The Ancient Monuments Bill

RECENT events have demonstrated beyond all question that the revision of our Acts for the protection of ancient monuments is a vital necessity. Stonehenge, the greatest of all our relics of the past, but a national possession only by private benefaction, was within an ace of permanent disfigurement and vulgarisation. It was saved only by a national appeal for funds to purchase the adjacent land. The Roman Wall, a monument no less unique and equally dependent upon its surroundings for its full significance and its appeal to the historic imagination, was and still is, in danger from an act of vandalism which would devastate one of the most characteristic stretches in its whole range. Happily, the proposals to exploit the natural resources of that area, which entailed the quarrying of some millions of tons of stone, with an illusory limitation that operations were to extend only over a brief period of years, were not allowed to pass unchallenged. The effect of the influential protest which followed the announcement of what was proposed is to be seen in the provisions of the Bill to amend the Ancient Monuments Acts which was introduced into the House of Lords by Lord Ponsonby on Dec. 3, and of which the text is now available.

In at least three directions the new Bill extends the principles of previous Acts. It enlarges the powers of the Commissioners of Works in the matter of schemes of preservation, in the range of their expenditure, and in enabling them to prohibit the exportation of ancient monuments from the country.

Under § 22 of the Act of 1913, the expression

"monument" it is laid down, "includes the site of any such monument, or of any remains thereof, and any part of the adjoining land which may be required for the purpose of fencing, covering in, or otherwise preserving the monument from injury, and also includes the means of access thereto." To a certain extent this was a compromise with the rights of private property, and in fact, in reserving to the public the means of access, together with so much land as was necessary for the purposes of preservation, as well as the site of the monument, at the time it was framed it did represent a very considerable advance in the assertion of the claims of the community as against the rights of the individual. It did no more, however, than claim the minimum essential for the protection of the structure of the monument or what remained of it. No attempt was made to safeguard its character in so far as this was dependent upon historical or natural setting.

In the case of historic buildings in urban surroundings any provision with such an end in view obviously would have been unpractical, while for other relics of antiquity, more especially, perhaps, prehistoric monuments, most of them situated in open land or isolated on moors and downs, such provision may have seemed unnecessary. It was not foreseen that a vast extension of motor traffic was at hand which would bring in its train an increase in the number of excursionists for whose entertainment and refreshment provision would be made, as well as a wider distribution of bungalow towns and suburban villadom. But the refreshment booth and the bungalow which, equally with the buildings for which the Government was responsible, menaced Stonehenge, are as nothing compared with the far graver danger from the demand for road metal, enormously increased by the provision of arterial roads and prepared surfaces for motor traffic. The quarrying at Malvern serves to show what might happen in any district which provided suitable material, and the inevitable disfigurement which threatens the countryside once guarded by the Roman Wall.

The gravity of the situation which has arisen from the development of modern social and commercial conditions cannot be too strongly emphasised. From one point of view it calls for, from another it justifies, the extension of the powers of the Commissioners of Works in dealing with ancient monuments. It is proposed to enact that the Commissioners may frame schemes for preserving the amenities of ancient monuments and that such schemes may provide for prohibiting or restricting building works, the felling of trees, quarrying and excavations, and for otherwise restricting the user of land within the controlled area. Further, in the definition of an ancient monument for this purpose and in so far as affects the acquisition, guardianship, receipt of voluntary contributions towards maintenance, and the transfer of ancient monuments, the term is extended to include any land comprising or adjacent to an ancient monument which, in the opinion of the Commissioners or the local authority, is 'reasonably required for the purpose of maintaining the monument or its amenities, or for providing or facilitating access, or for the exercise of proper control or management.'

It will be seen that under the provisions of the Bill it is proposed to give the Commissioners wide powers. Not only may they prohibit any action of the owner or his representatives in the vicinity of the monument which would be likely to be injurious or unsightly, but according to their interpretation of what constitutes the amenities of the monument, they themselves may determine the area to which that prohibition extends. In view of the past record of the Commissioners in the action they have taken in relation to ancient monuments, it is improbable that their interpretation of their powers under these provisions will be such as to be regarded as unduly harsh. The rights of the owner, however, are now to be protected by the provision that a preservation scheme may provide for compensation to persons whose property is injured by the scheme. When no such provision for compensation is made, objection to the scheme may be raised, within three months of the date of the order confirming it, by any person so affected. In that event the scheme shall cease to have effect two years from the said date unless it is confirmed by Parliament. Thus the Act would ensure a period during which the monument would be fully protected while the case was argued on either side. Expert opinion would obtain a hearing, and it may be assumed the public would be informed through the Press of the merits of the case. The action of Parliament eventually would ensure that a weight of opinion in favour of the scheme would prevail. By a similar provision for objection in the case of a preservation order which places the monument under the protection of the Commissioners, the owner is placed in a more favourable position, as under the existing Act there is no opportunity for appeal until the Bill to confirm the order is before Parliament.

The Bill also proposes to enlarge the powers of

the Commissioners in the matter of finance Unlike the Ancient Monuments Acts of certain other countries, such, for example, as Switzerland, the British Acts have made no adequate provision for the maintenance of ancient monuments At present the powers of the Commissioners in respect of preservation and upkeep are confined to those monuments of which they are owners by transfer or of which they have been constituted the guardians by a deed executed by the owners The powers of local authorities are wider, for they may, if they think fit, bear the cost or contribute towards the cost of preserving, maintaining, and managing monuments of which they are not the owners and guardians, provided the monuments are in or near the area for which they are the authority These powers, however, it will be noted, are permissive only The responsibility for a monument which is the subject of a preservation order, but of which the Commissioners or the local authority have not been constituted owners or guardians by deed, falls upon the owner , but he is under no compulsion to maintain The results in some cases have been disastrous

To some extent the difficulty is met under the provisions of the new Bill The powers of the Commissioners and local authorities are enlarged in the case of monuments of which they are guardians It is proposed that they should now be empowered to incur expenditure on excavating and examining such monuments , while in the case of monuments of which the Commissioners are not owners or guardians, they will be empowered to undertake and pay for "work" While it may be presumed that such authorisation would not cover the cost of maintenance, it could be made to cover urgent work essential to preservation

It will be noted that the work of excavation is here added to the permissive powers of both the Commissioners and local authorities The Bill also gives the Commissioners power to enter upon any land believed to contain an ancient monument and excavate for purposes of examination, except that if that land be occupied in connexion with a dwelling-house, or in private ownership, the consent of the occupier or owner is required

A further provision as regards finance would empower the Commissioners to bear the expense in whole or part incurred by an authority through preserving the amenities of an ancient monument in carrying out a scheme under the Town Planning Act, 1925

As a final measure of protection, it is proposed that the Commissioners may by order prohibit the export from Great Britain of any monument or any part of it This order will continue in force until any order is made revoking it It shall also be open to a local authority to obtain an injunction against the exportation of an ancient monument by application in the county court of the area in which the monument or any part of it is situated

The faulty definition of a monument, which specifically stated that it was a 'structure' or an 'erection', is changed An amendment was desirable here in order to bring within the class of 'ancient monuments' remains of archæological interest which could not be regarded as either "Monument" will now include "any building, structure, or other work, whether above or below the surface of the land and any cave or excavation"

Our ancient monuments have suffered grievously in the past from lack of adequate attention, and many a priceless relic has vanished or has been mutilated, both before and since the passing of the Act of 1882, through public apathy or official indifference There are signs that a healthier public opinion, more fully alive to the significance of the ancient monument, is on the increase If the Bill now before Parliament becomes law, as it should, and with no undue restriction laid upon the authorities whose duty it will be to administer it, the nation will be one stage nearer the complete realisation that in relation to the material evidence of the past, to day is at best the trustee of to morrow

The Twilight of Selenium

The Selenium Cell its Properties and Applications By George P Barnard Pp xxix + 331 (London Constable and Co , Ltd , 1930) 35s net

IT is a remarkable fact that in spite of the keen interest displayed in selenium ever since the discovery of its response to light fifty-eight years ago, no complete treatise on its properties has appeared in English until now Students have had to rely on the small German handbooks of Ruhmer and of Ries, or the compendium, "Il Selenio", published by Bianchi in 1919 If Mr Barnard had done no more than compile his 50 pages of excellent bibliography he would have conferred a considerable benefit on the scientific public But his book does much more than that

The study of the properties of selenium has reached a peculiar position The reaction following upon the earlier claims of inventors which failed to materialise has been so severe that the excellent work of more recent days has had to disguise itself,

so to speak, under pseudonyms Thus, television by means of infra red rays and selenium is called '*noctovision*', and a powerful London company for the manufacture and utilisation of selenium cells is known under the name of 'Radiovisor' There has never been a time at which more selenium cells were constructed and used, or when such rapid and solid progress was made in the study of their properties But few dare confess to it It is the twilight of selenium, the eclipse of the 'moon element'

When, in 1872, the light sensitiveness of selenium was discovered, Mr Shelford Bidwell said at the Society of Telegraph Engineers "Mr Preece has told us that by the aid of the microphone the tramp of a fly can be heard, resembling that of a horse walking over a wooden bridge, but I can tell you something which, to my mind, is still more wonderful that by the aid of the telephone, I have heard a ray of light fall on a bar of metal"

Everyone would have expected that after such an introduction the combined efforts of the scientific world would have sufficed to unravel the secrets of the marvellous substance which presented such a phenomenon Yet, fifty five years after, Prof Gudden, who has spent a lifetime in studying photoelectric phenomena in crystals, says "It is as hopeless to expect to understand what happens in selenium from the observation of selenium cells as it would be to determine the laws of vibration from the investigation of a creaking hinge"

Prof F C Brown is one of those who spent many years investigating large single crystals of selenium, but his work has not yet reached a satisfactory conclusion Gudden and Pohl have at all events, established one basic fact, namely, that in the insulating red form of selenium the effect of light upon the conductivity is both instantaneous and linear, though reckoned in micro micro amperes These red crystals have, according to Kyropoulos, a refractive index so high as 3 5 and obey Maxwell's law of refraction Much of the work on selenium of the next fifty years will no doubt be done on red selenium

When the D C conductivity of a substance is to be studied, we must, unfortunately, have electrodes, and selenium with electrodes constitutes a 'selenium cell' It should not surpass the ingenuity of our physicists to make the monoclinic crystals of conducting selenium arrange themselves in a regular and reproducible order, and to find an electrode, say of carbon, which has no chemical effect upon the substance We know that the square root law of light action is obeyed at faint illuminations down to very low values, and that is some foundation

There used to be a slogan in the Cavendish Laboratory at Cambridge when anything difficult had to be undertaken "Do it with selenium!" (pronounced, in defiance of Greek etymology, "selenium"), and Mr Barnard certainly enumerates an imposing array of results achieved by the 'creaking hinge' Fire and burglar alarms, automatic machines for counting stamp cancellations and even carcases, street lighting and train control, the mechanical estimation of fog and smoke density, and the control of camera shutters, are some of the successful applications of selenium Cox's magnifier of cable signals is fully described, as is Symonds's ingenious device for counting interference fringes This and the optophone could not possibly function with any form of photoelectric cell

When we come to the applications of intermittent light we are on less difficult ground, for all considerations of the zero in the dark can be eliminated or disregarded The only element that matters is the amplitude of the response

It has been found that selenium responds to notes of a frequency of 12,000 hertz It is therefore capable, in spite of its 'lag', of following the whole gamut of the notes used in music Theoretically, its response ought to vary inversely as the pitch, and a correction would have to be applied to make the higher notes stronger This would be inconvenient but for the fact that every reproducer devised so far must be corrected in one sense or the other Usually it is the lower notes that want strengthening The correction is the easier for the fact that there is plenty of current to spare Prof Thirring showed recently that selenium gives from 1000 to 1,000,000 times as much response as any photoelectric cell

A most valuable feature of this excellent book is the collection of chemical, optical, and electrical constants of selenium Everyone will naturally turn to these tables for information as to the resistivity, only to be told that it lies somewhere between 10^5 and 10^{10} ohms/cm ^{3} The figure 10^6 given by Siemens might have been quoted as an approximate practical guide E E F D'A

Immunisation of Plants

L' immunità nelle piante Per D Carbone e C Arnaudi (Monografie dell' Istituto Sieroterapico Milanese) Pp xii + 274 + 3 tavole (Milano Istituto Sieroterapico Milanese, 1930) 25 lire

DISEASE in plants is a subject which sooner or later brings to the mind of initiated and uninitiated alike the possibility of assisting our crop and ornamental plants with some of the more

recent discoveries in human and animal pathology which are in daily use for reducing the ravages of disease Realising that the results of the simplest operations in animal and vegetable therapeutics are not exactly similar, and that the structure and functions of the body parts of animals and of plants have little in common, it is encouraging to find that the more complex application of serum and vaccine therapy to plants is being continuously and seriously studied in Italy by the joint work of Dr D Carbone and Dr C Arnaudi, who, in this latest monograph from the Institute of Serotherapy of Milan, have reviewed the whole subject of immunity in animals and plants and the practical applications of the knowledge gained by their work

In England the published opinions of some of our prominent physiologists and plant pathologists show that there is little sympathy with the view that disease resistance can be secured in plants by methods which are successful in animal pathology, it being asserted that in plants a reaction to disease is localised and not found, as generally in animals, throughout the body, moreover, there is no blood stream by which anti bodies can be distributed throughout the plant It is further pointed out that in plants—and this, of course, applies to agricultural crops—new organs (roots, branches, flowers, seeds) are being continually produced, necessitating the rapid spread of the immunising factor, and unless there is some prospect that acquired immunity will be transmitted to the freshly developing organs, the study of serum and vaccine therapy in plants is likely to receive meagre support Scientific workers, however, are not daunted by difficulties, and certainly not by those which are only suggested It is with a feeling of admiration, therefore, that we note these authors have 'nailed their colours to the mast', for on the cover of their work appear some words of Sir J C Bose "Animal life finds an echo in the vast inarticulate life of plants The vital processes of the one and of the other are guided by identical laws"

The title of the book conveys no indication that it is only slightly concerned with the natural immunity of plants and chiefly with the serotherapeutical aspect Prof S Belfanti, in his preface, introduces this monograph as one result of a plea for unity and interchange of ideas which he made at the Perugia Congress of Italian Microbiology in 1929 He bewails the splitting of microbiology into autonomous branches, and suggests physiopathology as a science comprising the study of the conditions which determine the common pathological state of all living beings

The terminology of animal immunity is dealt with in the first thirty pages, and examples are given when each definition of a term is discussed A special section is devoted to the immunity reactions of certain of the lower animals, since these are not so far removed from plants as are the vertebrates

An insight is next given of the congenital immunity naturally present in plants, touching on the subject of specialisation of parasitism, Dr Arnaudi criticises adversely the modern tendency to multiply the number of biologic forms of a parasite An attempt is not made to give a complete review of the literature, and discussion of certain work is avoided when this is highly specialised and does not, in the author's opinion, assist in obtaining a general view of the subject It is somewhat surprising, however, that no mention is made of well known investigations on the grafting of immune and susceptible plants, since the authors have been deeply concerned with the possibility of transportation of immunity factors in the sap Very little original work is included in this first discussional part of the monograph, a method of technique, however, is given for the culture *in vitro* of plant tissues and the maintenance of botanical sections alive for about a month Dr Arnaudi thinks that eventually this will enable the phases of symbiosis or of infection and the corresponding cell reactions to be followed exactly

Chap III, on acquired immunity in plants, begins Part 2 of the book Some few facts are brought forward in an attempt to show that phenomena of plant and animal resistance to disease are not altogether dissimilar Dr Arnaudi describes the work of others and one of his own experiments with *Bacterium tumefaciens* on geraniums when dealing with resistance to superinfection He summarises the results of eight experimenters with vaccination of plants and details two of his own vaccination studies Complete immunity as a result of vaccination is claimed in begonia and kidney bean from *Botrytis cinerea*, in orchids from *Orcheomyces* spp and *Rhizoctonia repens*, and in bean from *Bacillus carotovorus* In other cases a degree of resistance is gained but the period of duration of the immunising effect is short, varying from one week to one month The mechanism and technique of vaccination are discussed A section on acquired passive immunity includes description of an experiment in which galls on geranium were made to shrivel up by keeping the cut stems in a liquid containing

anti-*B tumefaciens* serum obtained from a rabbit By the same method a fresh infection by the parasite was made to fail

In the ninety pages of Chap iv, which delves deeply into the relation of animal immunity to that of plants, the whole subject of the presence or absence in plants of pseudo antibodies and the various antibodies known to human bacteriologists is exhaustively dealt with by Dr Carbone Knowledge accumulated by other workers is given *in extenso*, and original experiments are detailed which must have required truly laborious technique An example is that involved in adapting and performing the complement fixation test It is not shown that plants do or do not produce antibodies

The final chapter, entitled " Phyto Immunity in Practice ", is somewhat disappointing, as are also the conclusions arrived at It appears that in our desire for crop plants resistant to disease, we are to rely rather on the work of geneticists than on being able to confer acquired immunity Moreover, the reader is left with the idea that an enormous amount of arduous work has been performed and much has been written with insufficient results to warrant the inclusion of a chapter with this title There can be no doubt of the great ability of these investigators, however, who are to be congratulated on having accomplished much in laying a foundation for future work W M WARE

Alchemical Manuscripts

Union Académique Internationale Catalogue of Latin and Vernacular Alchemical Manuscripts in Great Britain and Ireland dating from before the XVI Century By Dorothea Waley Singer, assisted by Annie Anderson and Robina Addis Vol 2 Pp viii + 329 755 (Brussels Maurice Lamertin, 1930) 10 Belgas

THE publication of a second part of Mrs Singer's catalogue of alchemical manuscripts enables us to form some idea of its usefulness as a guide to the *Corpus Scriptorum Alchemistarum*, a usefulness which will be materially enhanced by a promised third part containing indexes of names, places, and first lines It would be hard to exaggerate the importance of this work to the historian of scientific thought in western Europe, we are here put in possession of a key to the materials from which the story of the development of alchemical theory can be written Up to now, no historian of chemistry except Kopp, and in a lesser degree Berthelot, has gone to the manuscript sources for his information, all of them, when they have not copied one from another, have aimlessly turned a few pages of the printed texts and extracted some sentences from them to small profit

The literature of alchemy was collected in the seventeenth century by Zetzner in six closely printed volumes and later by Manget in two folios—mainly from printed sources The earliest treatises have in the main escaped printing down to our own days, while those of the early texts reproduced are incredibly corrupt by the accretion of notes and interlineations and by accidental omissions But no thorough revision of the classics of Latin alchemy will be possible until the scholars of France and Italy have followed the example here set In the meantime, any student of philosophy, equipped with some knowledge of the medieval Aristotle, will find here a rich field open to him

The catalogue is arranged in the order of the historic development of alchemical thought, first of treatises of Byzantine or Hellenic origin such as the " Turba Philosophorum ", the " Emerald Table ", and other treatises ascribed to Greek authors, real or apocryphal, then to Arabic authors, to Latin authors in prose, to anonymous treatises, to the large body of alchemical verse, to chemical crafts, and to receipts of all descriptions The named treatises were included in the first part, the remainder are here given and their study throws an interesting light on the processes of chemical technology in the Middle Ages One does not see how this arrangement can be improved upon, but it must not be allowed to mask the fact that alchemical theory in western Europe was entirely Arabist in its origin and growth Chemical technology is purely Byzantine and Hellenic, but it was altogether divorced from theory, and the " Turba " is never quoted by any writer in the first century and a half of alchemical literature But though Greek thought had no direct action on Latin writers, it was the ultimate source of Arabic alchemy as regards the theory of metals, the elixir of life being apparently of Chinese origin No doubt a few Byzantine adepts found their way into the west—Roger Bacon mentions a Greek he had known, and there is the still earlier case of the Jew of Bremen

The story of translation from the Arabic begins with Robert of Chester in 1144, Plato of Tivoli and Hugo Sanctallensis, and goes on to Gerard of Cremona, who before his death in 1187 translated three classics of alchemy—two of them only printed in our own time, by Berthelot and the writer A number of treatises were translated

before the middle of the thirteenth century, as shown by the quotations from them in the "Speculum Naturale" of Vincent of Beauvais (1245), the alchemical writings of Roger Bacon ending 1267, and the writings of Albertus Magnus on minerals and the "Speculum Astronomicum" St Thomas also accepts the scientific possibility of alchemy The series of philosophic writers on alchemy closes with Arnold of Villanova at the end of the thirteenth century Two expository works of some value as accounts of current theory were written in the first half of the fourteenth century—the "Margarita Novella" of Petrus Bonus and the "Quintessence" of Johannes de Rupescissa—but no new ideas are to be found in them, the developments of the Aristotelian theory of matter had been exhausted and the pursuit of the transmutation of metals had been abandoned, not as impossible but as impracticable The fifteenth century brings in a spate of tracts, all with high-sounding claims, reiterating the old formulæ and clothed in the old mystification of language

It is impossible to rate too highly the unwearying industry of Mrs Singer and her helpers, they have searched and almost re-catalogued not only the great collections of Sloane and Harley in the British Museum, of Digby and Ashmole at Oxford, but also every corner of every library, great or small, in Great Britain, and have revealed a scarcely suspected wealth of manuscripts When their provenance is examined and tabulated some interesting results may appear It would seem that the earliest centre of alchemical activity was in northern Italy, that from there it spread to the south of France, thence to Paris, becoming common in England in the fourteenth century, as witness the "Canon's Yeoman's Tale" of Chaucer Its progress is marked by the Act of 1403 making it illegal—alchemy had become a shield for coiners of false money The Act, however, was powerless to stay the flood of students and treatises—some of them voluminous like those ascribed to Ramon Lull, which first appear in 1443 (translated from a non-existent Catalan original) There are, too, a number of official licences to practise alchemy on record, and more remarkable still, three Royal Commissions to inquire into its possibilities as a means of paying the King's debts—the last a very strong one consisting of four bishops and a number of high officials It would be interesting if Mrs Singer, who has ferreted out of the Record Office some alchemical tracts, could come upon the reports of these Commissions Licences and treatises come to an end in England at the last quarter of the fifteenth century, 1476 for the licences, 1471 and 1477 for the treatises of Ripley and Norton Commerce was offering a more certain road to wealth than alchemy

In the thousands of extracts of more or less barbarous Latin in badly written, badly spelled and contracted manuscripts here printed, it is not to be expected that there should be no doubtful readings, but speaking with no inconsiderable experience of medieval hands, I can say that the work as a whole would do credit to an expert palæographer and bibliographer It is the sort of work that only an enthusiast would undertake, and it betrays the hand of an amateur only in the desire for completeness which has led Mrs Singer to give us lists of the manuscripts of the "Canterbury Tales" and such like works which have been made the subject of intensive study elsewhere Mrs Singer and her assistants have earned the hearty thanks of all who are interested in the history of scientific thought ROBERT STEELE

Gumbotils and the Pleistocene Succession

Iowa Geological Survey Vol 34 *The Pre Illinoian Geology of Iowa* By George F Kay and Earl T Apfel Pp 304 + 3 plates (Iowa Iowa Geological Survey, 1929)

SINCE the middle of the last century, certain sands and gravels which occur embedded in glacial boulder clays have been interpreted as accumulations of genial interglacial periods A similar construction has been placed upon the peats and forest trees which over the same time have been derived at intervals and from widely separated localities in these layers in northern Europe and North America In more recent times the importance of deeply weathered boulder-clays as indicators of interglacial conditions has been frequently stressed, as by A Jentzsch and C Gagel in Germany, and by A Penck and E Brueckner in the region of the Alpine glaciation These weathered layers, however, have never had quite the same emphasis placed upon them in connexion with the recognition and extensive mapping of the interglacial horizons as by Dr G F Kay and his colleagues on the Iowa Geological Survey during the last ten years or so It has to be admitted that the effectiveness of the old methods is definitely limited, for the sands and gravels are impersistent and of diverse origin, while the peats and trees are few and fragmentary and of local occurrence only The weathered clays or 'gumbotils', on the other hand, are of wide extent and considerable

thickness and can be mapped as stratigraphical units

The gumbotil, to use the term introduced by Dr Kay, is a grey to dark coloured clay, very sticky—'gumbo' is a sticky clay—destitute of lamination and stratification It is tenacious when dry and breaks with starch like or polyhedral cracks when wet It represents the thoroughly leached and oxidised boulder clay resulting from the chemical weathering of the till on wide, flat surfaces of country during interglacial periods, aided by the action of frost, wind, sun, and animals and the organic acids arising from the growth of vegetation The iron, silica, colloidal clays, and simpler colloidal silicates have been carried downwards from the surface and the calcareous materials have been leached out, though to a shallower depth than that reached by the oxidation In this way, the percentage of alumina in the surface layers has increased at the expense of the other constituents

From the point of view of Pleistocene geology, the State of Iowa is probably the most important in North America It lay within the influence of the Labrador and Keewatin ice sheets, and, perhaps partly because of this position, served during the nineties of last century as the battle ground where the idea of the multiplicity of the glacial period definitely obtained the victory in North America The successive drifts, denoted the Nebraskan, Kansan, Illinoian, Iowan, and Wisconsin (separated by the interglacial horizons of the Aftonian, Yarmouth, Sangamon, and Peorian), are all to be found within its borders, while its records of the inter glacial periods are probably fuller, better preserved, and have been studied in more detail than in any other part of America

The mapping of the gumbotils by Dr Kay and his colleagues during the last eighteen years has added greatly to our knowledge of the character and distribution of the different drifts and the interglacial layers The Nebraskan drift, averaging 100 feet in thickness, is thought to have covered originally the entire State, not excluding its north-east corner, formerly contained within the 'Driftless Area', where isolated patches of an old drift have been observed on the remnants of the Pre Pleistocene peneplains The Kansan drift, about 40 feet thick, covered the whole State, except the so called 'Driftless Area' The Illinoian drift occurs in the south-east, the Iowan drift in the north-central third, and the north west The Wisconsin drift, characterised by its fresh and youthful features and immature drainage, is restricted to the north west central part of the State Plate II of this Report gives a very welcome map of the areal distribution of the several drifts as determined by the old sections and by the new ones exposed in the making of more than 15,000 miles of graded roads

The Aftonian and Yarmouth interglacial periods, according to the authors, are each to be measured by hundreds of thousands of years The steep-walled and drift buried valleys, which are distinctive features of the bedrock topography, are thought to have been cut, not in preglacial times as is generally held, but chiefly in Aftonian times The depth of the Aftonian erosion is locally so great as 400 feet or more, though figures of 200 feet are more common

The belief in such prolonged interglacial intervals seems to be counter to the trend of thought on the eastern side of the Atlantic, where the tendency is to curtail the length of the Glacial Period

The average thickness of the Nebraskan gumbotil is 8 feet, of the Kansan, more than 11 feet, and of the Illinoian, 3 feet The Iowan and Wisconsin tills have no gumbotils

A description of the drifts and their gumbotils forms the bulk of the present book, while one chapter (iii) is devoted to a complete and invaluable summary of the history of investigation and classification of the Pleistocene accumulations of the State It contains a restatement of the case for the retention of the Iowan glaciation as a separate glaciation, a view which has been repeatedly questioned by Leverett, partly from field studies, partly from the difficulty of equating five glaciations in North America with four glaciations in Europe

The report is well illustrated with maps and pictures The usefulness of the photographs, some of which are by no means clear, would have been enhanced by the insertion of marginal names and lines opposite the different horizons they portray

Our Bookshelf

Death Customs an Analytical Study of Burial Rites By Dr E Bendann (The History of Civilization Series) Pp xiii+304 (London Kegan Paul and Co, Ltd, New York Alfred A Knopf, 1930) 12*s* 6*d* net

MISS BENDANN has brought together the evidence bearing upon the conception of death among the peoples of four areas—Australia, Melanesia, northern Siberia, and India The object of her analysis is to demonstrate the varying effect of the character of the concept upon death and burial customs For this purpose, under the headings 'similarities' and 'differences', various beliefs, rites, and customs,

such as the origin of death, causes of death, disposal of the dead, dread of the spirit, mourning, taboo, the special function of women in mourning rites, and so forth, are examined in detail She deals " rather cavalierly ", as Dr Goldenweiser puts it in his preface, with Spencer, Tylor, Frazer, Rivers, and others, but whether her criticism is also judicious, it may be left to the reader to decide Her own conclusion is that " we have no authority to speak of a uniform line of development which carries man from one stage to another ", while certain kinds of parallel sequence which make for an advance in cultural development are thought to be due " not so much to historical causes as to psychological ones " Thus the author's final position represents a compromise between the evolutionary point of view and that of the historical school The death complex is regarded as in part composed of certain inherent psychic features, and the only elements which are held to be exclusively characteristic of the death situation are mourning customs as such and the ideas in regard to the life after death

The Rôle of Research in the Development of Forestry in North America By I W Bailey and H A Spoehr Pp xiv + 118 (New York The Macmillan Co, 1929) 6s net

THE primary object of this book is, the authors state, to determine how and to what extent certain categories of the natural sciences may be of service to sylviculture during different stages of its development In connexion with the sciences, the authors consider that there are two distinct methods of investigating complex biological phenomena - one the extensive observational method of the descriptive sciences, and the other the intensive analytical method of the basic experimental sciences

The subject is dealt with under the heads Agriculture as contrasted with sylviculture, ie research and its application in sylviculture as contrasted with agriculture and medicine, present status of forestry in the United States, existing agencies for descriptive and empirical investigation in forestry, can research in the basic experimental aspects of forestry be developed and handled adequately by existing agencies, and, finally, new agencies required for research, particularly in the fundamental physiological and ecological aspects of forestry There is much in this little book which should appeal to a wider circle of foresters than those in North America for whom it is especially written, the authors may be congratulated on a most useful and interesting piece of work

Essays and Addresses Sociological, Biological and Psychological By a Surgeon Pp xiii + 277 (London H K Lewis and Co, Ltd, 1930) 10s 6d net

THIS book is a collection of lectures, addresses, and articles published during the last twenty years, recording thoughts and opinions on various social problems approached from the biological point of view Although the individual chapter subjects vary considerably, three fundamental principles are apparent throughout the volume They are the necessity for a fuller recognition of the influence of evolution in all human affairs, the importance of hereditary constitution, and the need for a closer application of biological principles in the attempt to solve social problems The conclusions put forward are not concerned with theories and principles alone In a discussion of some causes of racial decay, a practical method of national stocktaking is suggested, a means of ascertaining quality as well as quantity As the considered opinions of one who combines a scientific training with a close study of racial welfare requirements, and who is held in the highest esteem in his own profession—the authorship is but thinly veiled—this book merits the attention of all whose duty it is to guide legislation as applied to the improvement of national health

The Archæology of Roman Britain By R G Collingwood (Methuen's Handbooks of Archæology) Pp xvi + 293 + 8 plates (London Methuen and Co, Ltd, 1930) 16s net

THIS is a book which was badly needed indeed The literature of Roman Britain is highly specialised, difficult of access, and extremely technical Mr Collingwood has aimed at supplying the elementary but fundamental knowledge which is essential in entering upon the study of Romano British culture Still more will it help those who, not being specialists, wish to follow intelligently the reports of results which are being achieved season by season on a number of sites up and down the country Each of the different classes of antiquities is here described in detail—roads, camps, forts, towns, villas, temples, native settlements, and so forth Especially valuable are the chapters which deal with the pottery, both Samian and coarse ware The chapter dealing with the latter is of interest not merely to the beginner but also to the expert, for in it Mr Collingwood has made a first attempt to form a series of nearly a hundred dated types The very full illustration from drawings by the author, both in this chapter and in that dealing with brooches, will be found invaluable Mr Collingwood has been at great pains to give every assistance to the student

The Truth about Cancer Published for the British Empire Cancer Campaign Pp xv + 124 (London John Murray, 1930) 2s 6d net

THE various committees of the British Empire Cancer Campaign which have been concerned in the preparation of this small book for the general public have succeeded very well in a difficult task The ' man in the street ' is perhaps not much concerned to understand the nature of malignant tumours, but he will certainly be less liable to die of cancer if he will absorb the broad facts about its causation and treatment which are set out so plainly here More stress might have been laid on prevention, on the special efficacy of tar and soot in causation, on the lessons to be learned from the fact that industrial labourers have much more cancer than professional men The account of the early symptoms is particularly well done, and should bring many people to their doctors at a time when a cure is reasonably within range

Fluorescence of Mercury Vapour under Atomic and Molecular Absorption

IT is familiar that mercury vapour under pressures of a few centimetres of mercury gives a green fluorescence when excited by wave-lengths near the resonance line λ2537. Proceeding away from the resonance line, I have observed the fluorescence with wave-lengths so long as λ3450, though at this extremely low excitation dense vapour is needed. This note deals with excitation near the resonance line.

The fluorescence is much brighter near the entrance than elsewhere, due to rapid exhaustion of the most effective constituents of the exciting radiation. I have emphasised that there is a *discontinuity of intensity* as we proceed along the beam, and this is attributed to the existence of two kinds of absorption, atomic and molecular. Atomic absorption is dominant at first. The radiation capable of this kind of absorption is limited to about 0.05 A. on either side of the resonance line. I call the fluorescence from it the *core* effect, and the much weaker fluorescence, due to outlying radiation, the *wing* effect. The latter does not suffer rapid extinction as the beam traverses the vessel. Some continental physicists who have been interested in the question are unable to accept this point of view, and consider the apparent discontinuity an illusion, regarding the fluorescence absorption as molecular in every case.

A full discussion will be published later. I write now to record that the reality of the distinction between the wing and the core effect is confirmed by observing what happens when a suitable addition of hydrogen gas is made to the mercury vapour. It is easy to adjust the hydrogen admixture so as to extinguish completely the core effect, leaving the wing effect almost unaltered. I have obtained the latter with hydrogen pressures so high as 10 cm.

RAYLEIGH.

Evidence for a Stellar Origin of the Cosmic Ultra-penetrating Radiation

WHILE in former years all observers were agreed that the sun does not contribute any noticeable amount to the total intensity of the cosmic ultra-radiation, the increase in the sensitivity of the apparatus used within recent years, and the increase in the number of observations made at different stations and under different experimental conditions, makes it possible to investigate once more whether the influence of the sun is altogether negligible.

Very accurate and trustworthy registrations of the cosmic radiation have been carried out with Prof. G. Hoffmann's high pressure ionisation chamber at Muottas Muraigl (2456 m. above sea level) in the Engadine. These measurements show, beyond any doubt, that the average intensity of the radiation is somewhat greater in daytime than during the night. G. Hoffmann and F. Lindholm[1] give the average difference between day and night intensities as 0.12 mA., ~0.0125 ions per c.c. per sec. while the apparatus was unscreened from above, and 0.04 mA., ~0.0042 *I* with a lead screening of 6 cm. and 9 cm. thickness. (The letter '*I*' always denotes "ions per c.c. and sec.".) F. Lindholm,[2] with the same apparatus, found from longer series of observations (8 months) the values in the accompanying table (see Table 6 of his paper).

In Hoffmann and Lindholm's apparatus a compensation current of one milliampere corresponds to an ionisation of 0.104 *I*. Therefore the total intensity of the ultra-radiation with the apparatus unscreened from above was about 2.50 *I* at Muottas Muraigl.

The difference between day and night intensity can be taken, provisionally at least, as the actual intensity of the solar penetrating radiation. One can see at once that at Muottas Muraigl, 2456 m. above sea level, about one-half of this solar radiation component is able to penetrate through 10 cm. of lead. This component is therefore far more penetrating than the gamma rays from radioactive substances. If we assume that all of the above mentioned 0.011 *I* is of solar origin, we can compute the absorption coefficient in lead μ_{Pb} (it will suffice to take the case of perpendicular incidence) from the equation

$I = I_0 e^{-\mu_{Pb} d}$ taking $I_0 = 0.011$, $I = 0.0058$, and $d = 10$ cm.,

thus we obtain $\mu_{Pb} = 0.064$ cm^{-1} and the mass absorption coefficient $\left(\frac{\mu}{\rho}\right)_{Pb} = 5.7 \times 10^{-3}$ cm^2/gm.

This value is almost exactly equal to the mass absorption coefficient value of the total cosmic radiation at the same altitude ($(\mu/\rho)_{Pb} = 6.3 \times 10^{-3}$ cm^2/sec. as found by Büttner on the Eiger glacier 2.3 km. above sea level).[3] If we assume that part of the (0.011 *I*) difference between day and night values with unscreened apparatus is due to an increase in the average content of radium emanation and its products in the air during daytime, then we should get an even more pronounced hardness of the solar penetrating rays, that is, a smaller value for their mass absorption coefficient. Therefore we are justified in concluding that *the sun emits penetrating rays of at least the same penetrating power as the well-known cosmic ultra-radiation. The total amount of the solar penetrating rays (at 2456 m. above sea level) is about one-half per cent of the total intensity of the cosmic radiation, as it is seen from the accompanying table.* Of course, one might think it possible to explain the increase in the total radiation during daytime as due to an indirect influence of the sun (that is, an increase in the scattering of the ultra-rays by the heating of the atmosphere during the day). In this case, however, one would expect that this scattered radiation, represented by the difference between the day and night values, would be much softer than the general cosmic radiation; but this is in contradiction to the experimental results analysed above.

Recent observations of R. Steinmaurer[4] on the summit of the Sonnblick (3100 m. above sea level) in the summer of 1929, made with three different instruments (two of the Kolhörster double loop electrometer type and one of the Wulf–Kolhörster type), also show clearly that the total ultra-radiation in daytime is slightly higher than at night; the difference amounts to about 0.7 per cent (0.06 *I*, average difference for the three forms of apparatus mentioned above, the total intensity on the Sonnblick being about 8.7 *I* with the screening open on the top). The increase of radiation was also observed with apparatus screened with 7 cm. iron all around, but the number of these observations on the Sonnblick is not sufficient for quantitative calculations. It may be mentioned that even in the old observations on the summit of the Obir (2000 m. above sea level), made by V. F. Hess and M. Kofler,[5] the solar influence is noticeable (the total intensity of the ultra-radiation plus earth radiation during the day being 11.11, during the night 11.09 *I*, in the average for 13 months), although at that

time the apparatus were not screened from the earth radiation The difference of 0 02 I was—at that time—considered as practically amounting to zero

Observations with apparatus of the Wulf- or Kolhörster type for shorter periods (like those of Kolhörster-v Salis on the Jungfraujoch, on the Mönch, and of Buttner at other places in the Alps) naturally do not show the influence of the solar component of the ultra-rays, on account of the lesser degree of accuracy of the means, therefore Corlin,[6] using the observations on the Mönch and the Zugspitze, came to negative conclusions as to the solar influence From the data given below it is quite safe to conclude, according to the most accurate and most numerous observations at present available, that *the sun contributes an amount of about 0 5 per cent to the total intensity of the cosmic ultra radiation at 2 5 km above sea level The penetrating power of the solar ultra rays is at least as great as that of the total cosmic radiation* There is no doubt that this solar component of the ultra radiation is also present at lower levels, on account of its very small absolute intensity it will, of course, be far more difficult to prove its existence in these levels An analysis of the very accurate registrations of the total radiation by Hoffmann and Steinke in Königsberg and in Halle in this direction might be successful

Period	Number of Days	Armour open above		
		Mean Values		Difference (Day—Night)

If the sun, as the fixed star nearest to our planet, emits rays of about the same qualities as the total cosmic penetrating radiation, one cannot but assume that all fixed stars are sources of a radiation of similar qualities The sun being a relatively old star of the yellow dwarf type may, of course, be expected to yield far less total quantity of the ultra penetrating radiation than, for example, the younger giant stars Naturally, the ultra penetrating rays which we observe can only come from the outermost layers of the stars, since they are not able to penetrate material layers of more than a few hundred metres water equivalent

It is not possible, at present, to say more about the nature of these stellar ultra rays whether they are electrons or protons accelerated in cosmic electric fields, or indeed photons (quanta) created by atomic mass shrinking or annihilation processes This hypothesis of a partly stellar origin of the ultra penetrating cosmic radiation does not necessarily exclude the possibility that another part of this radiation is created in interstellar space by the formation of certain elements out of hydrogen, according to Eddington's and Millikan's ideas, although the principle of minimum hypothesis would rather induce us to try whether the stellar origin hypothesis, based on the experimental evidence of the solar ultra penetrating rays, would suffice to explain the observed facts

The conclusions put forward in this note certainly support the original ideas of Prof Nernst first mentioned in 1921[7] A few years ago, when the first results of observations on the daily period according to sidereal time were published, he wished that it were possible to increase the sensitivity of our apparatus until we could detect the ultra rays from a single stellar nebula or a single star I think the results put forward here indicate that a modest beginning has been made in this direction At least it has been possible now to detect the influence and the penetrating power of the ultra rays from the sun It may be added that the evidence here brought forward for a stellar origin of the cosmic ultra rays is completely independent of the existence of a daily period according to sidereal time, a subject which is still under discussion

An X-Ray Study of Mannitol, Dulcitol, and Mannose

A RECENT investigation, carried out at the Davy Faraday Laboratory of the Royal Institution, gave the following results for these three substances

Mannitol Space group, Q_4, $a = 8\ 65$ A $b = 16\ 90$ A, $c = 5\ 56$ A, density, 1 497 gm per c c, number of molecules per cell, 4

Dulcitol Space group, $C_{2h}{}^5$, $a = 8\ 61$ A, $b = 11\ 60$

A., $c = 9.05$ A., $\beta = 113° 45'$, density, 1.466 gm. per c.c., number of molecules per cell, 4.

Mannose. Space group, Q_4, $a = 7.62$ A., $b = 18.18$ A., $c = 5.67$ A., density, 1.501 gm. per c.c., number of molecules per cell, 4.

A study of the X-ray data suggests that in all three cases the long dimension of the molecule corresponds to the a axis; in the alcohols, the molecules appear to have the long chain configuration; in the sugar, that of the manno-pyranose ring, with the longest dimension in the direction of the a axis.

The reasons for assigning these structures to the various crystals will be discussed in a paper which will appear shortly.

Structure of the Crystal Lattice of Cellulose.

FROM an examination of the available data for cellulose and the sugars, we have formed the conclusion that the six-atom sugar ring is associated in the crystalline state with certain linear dimensions which are approximately constant, and that at least one of these dimensions usually corresponds to one of the axial lengths of the unit cell. The existing crystallographic data are as follows:

	a	b	c	Density
Native cellulose	8.3	10.3	7.9, $\beta = 84°$ [1]	1.52
Hydrate cellulose	8.14	10.3	9.14, $\beta = 62°$ [2]	1.56
Cellobiose	5.0	13.2	11.1 $\beta = 90°$ [3]	1.556
Sucrose	11.0	8.7	7.65, $\beta = 103\frac{1}{2}°$ [4]	1.588
Mannose	7.62	18.18	5.67 [4]	1.501
Glucose	10.40	14.89	4.99*	1.544
Fructose	8.06	10.06	9.12*	1.598
Sorbose	6.12	18.24	6.43*	1.654

* Calculated from the density, crystal class and axial ratios.

The most striking feature of the above list is the small variation in density shown by these saccharoses. This in itself strongly suggests an approximate close-packing of some molecular unit, but when we arrange the data as in the following table, it becomes still more apparent how the dimensions of this unit—undoubtedly the sugar ring with its side-chain—impress themselves on the dimensions of the various unit cells.

	Axial Dimension	Cross-sectional Product	
Native cellulose	10.3	$8.3 \times 7.9 \sin 84 = 65.2$	66.6
Hydrate cellulose	10.3	$9.14 \times 8.14 \sin 62 = 65.7$	
Cellobiose	11.1	$5.0 \times 13.2 = 66.0$	
Mannose	5.67	$(\frac{1}{2}\times)18.18 \times 7.62 = 69.3$	
Sucrose	11.0	$8.7 \times 7.65 \cos 13\frac{1}{2} = 64.7$	
Sucrose	7.65	$(\frac{1}{2}\times)11.0 \times 8.7 \cos 13\frac{1}{2} = 46.5$	51.7
Glucose	$(2\times)7.45$	$10.40 \times 4.99 = 51.9$	
Mannose	7.62	$5.67 \times (\frac{1}{2}\times)18.18 = 51.5$	
Mannose	$(4\times)4.55$	$5.67 \times 7.62 = 43.2$	41.0
Fructose	$(2\times)4.56$	$(2\times)5.03 \times 8.06 = 40.6$	
Sorbose	$(4\times)4.56$	$6.12 \times 6.43 = 39.3$	

Putting $xy = 66.6$, $yz = 51.7$, and $xz = 41.0$, in order to determine the mean values of x, y, and z respectively, gives $x = 7.27$, $y = 5.64$, and $z = 2 \times 4.58$. We suggest that the interpretation of these results is that on the average, the sugar ring takes about $4\frac{1}{2}$ A. normal to the ring, about $5\frac{1}{2}$ A. across the ring in the direction of the cellulose chains, and about $7\frac{1}{2}$ A. across the ring in the direction of the side-chain, $-CH_2OH$.

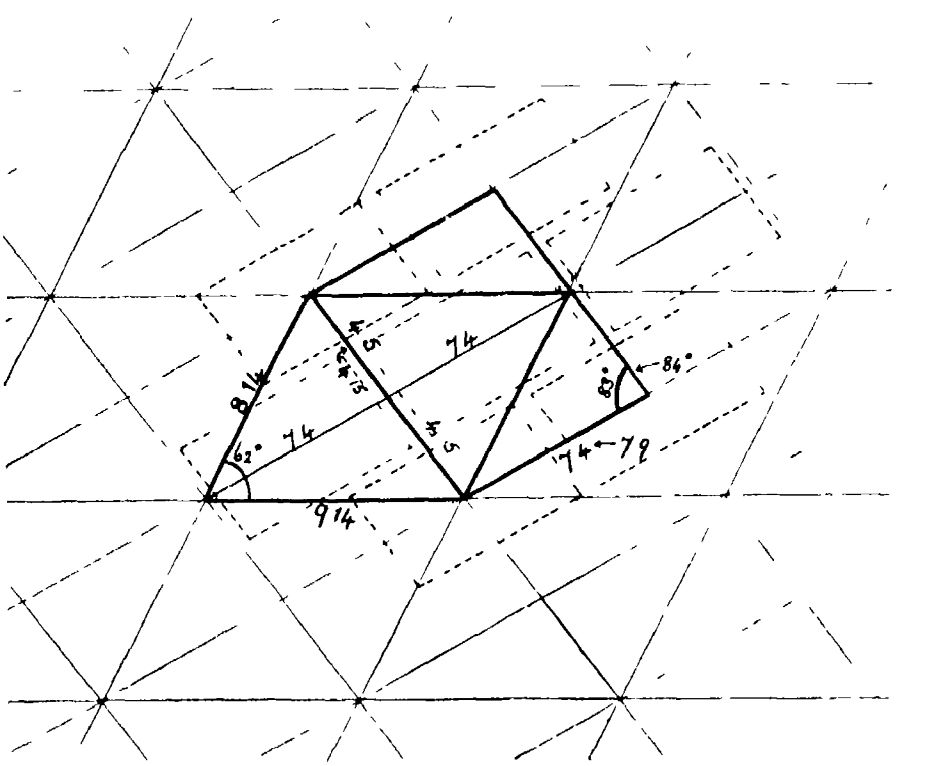

FIG. 1.

Applying now these values to the case of cellulose, we see that there is no *dimensional* reason why the plane of the hexagonal glucose residues should be taken parallel to the a axis (8.3 A.), as has been proposed by Meyer and Mark.[1] In fact, the balance of evidence, particularly the evidence to be derived from the dimensions of cellobiose and the stable form of cellulose (hydrate cellulose, mercerised cellulose), indicates that the plane of the rings should lie more nearly parallel to the c axis (7.9 A.).

The great advantage of this point of view lies in the way in which it links up the structures of native and mercerised cellulose, and in the simple picture which it offers of the mercerisation process. Fig. 1 shows diagrammatically how closely related are the two structures, and how small a change is required in order to pass from one to the other. The change in density is very small and it may be recalled that for some time it was believed that both native and mercerised cellulose gave rise to one and the same X-ray photograph. All this is quite in keeping with what we know of the changes in other dimorphous crystals.

Against these arguments must be placed the evi-

dence which has been adduced from intensity measurements But both the theory and practice of intensity measurements on natural fibres are in a very immature state, and it is risky to argue that any proposed structure of cellulose accounts for the paucity of X ray reflections, when a similar phenomenon is shown by other natural fibres, such as silk and hair, built up of totally different molecular units

Ovoviviparity in Sea-Snakes

IN a communication on this subject in NATURE of Oct 11, 1930, p 568, Dr Smith discusses my note on *Laticauda colubrina* I am quite aware that Dr Smith's statement that all sea snakes are viviparous was something more than a mere reiteration, but I consider that both he and previous authors have generalised from insufficient data

When I wrote my previous note, I was fully alive to the fact that the deposition of eggs might conceivably be an abnormal occurrence, brought about by captivity I have since had the opportunity of investigating the matter more fully, and had prepared an account (to appear in the *Bulletin of the Raffles Museum*, No 5, which will be published shortly), before Dr Smith's letter appeared

Witnesses whom I have no reason to doubt have found the eggs and observed hatching This takes place on islands near Singapore in June, July, and August

Four females kept in captivity produced eggs, none of which contained an embryo, although some of the eggs were laid a considerable time after the snakes arrived

In view of the evidence which I have collected, on one hand and Dr Smith's remarks on a specimen of this species, containing embryos, on the other, only one conclusion appears possible the species must be capable of either type of reproduction Either a local race inhabiting the islands near Singapore is oviparous, or the individual is influenced by the possibility or otherwise of access to dry land * Such an explanation is by no means impossible, the Laticaudinæ are definitely in a transitional state between a terrestrial and an aquatic habitat, ovoviviparity *is a form of oviparity, and far removed* from true viviparity, a mere question of the point in development at which the egg already a separate entity, is deposited The form of the skull and of the ventral shields, the method of casting the skin, the presence of ticks, all point to a shore habitat in the locally obtained specimens of *Laticauda colubrina* The flat tail and, possibly, the colour are the only adaptations to a marine life

Dr Smith mentions a specimen which deposited eggs at the Zoological Society's Gardens, I believe this to be a specimen recently obtained by me off Singapore, and dispatched to the Zoo It appears to have borne out its local provenance by depositing eggs during August The fact that the eggs were laid singly proves nothing, two of my specimens laid batches of six

On the general question of reproduction in sea-snakes, then, it appears that we may say that the Hydrophiinæ, *in those species that have been observed*, bring forth their young alive, but there is no evidence to show whether they are truly viviparous or ovoviviparous, of the Laticaudinæ, examples of oviparity and ovoviviparity have been observed, and it is possible that these two degrees of the same condition may take place within the bounds of a single species

NORMAN SMEDLEY
Raffles Museum, Singapore, Nov 8

* Semper's discovery of a female guarding her young on land is strong evidence of oviparity It is almost inconceivable that a snake which has developed ovoviviparity a definite adaptation to an aquatic life, should take the trouble to come ashore to deposit its young

Periodic Process in a Chemical Reaction

THE accompanying photograph (Fig 1) shows a rather remarkable case of a periodic process in a chemical reaction The object shown is a potassium photoelectric cell made in this laboratory The cell was made by the usual method in which, after careful baking out of the glass, potassium is introduced by

FIG 1

distillation from a reservoir sealed on to the vacuum system The potassium was then formed into a uniform layer on the bulb and the window opened by gentle heating

On sealing off the cell from the pumps a minute crack occurred behind the projecting tube which encloses the cathode lead An exceptionally small leak was thereby caused and the potassium layer oxidised very slowly Instead of oxidising uniformly, sharply marked rings were attacked first Even when the potassium was completely oxidised the rings were still visible, as the oxide in them was white while the remainder was a very pale yellow and finally the material in the rings turned to liquid potash solution while the remainder was still solid

The rings are roughly circular with centres at the crack, and the approximate radii of successive rings measured along the surface of the bulb are as follows

Curve No	Radius	Curve No	Radius
1	1 2 cm	8	3 3 cm
2	1 85	9	3 7
3	2 2	10	4 1
4	2 5	11	4 5
5	2 7	12	5 0
6	2 9	13	5 6
7	3 1	14	6 6
		15	7 7

The diameter of the glass bulb was 6 6 cm

The Photosensitised Decomposition of Nitrogen Trichloride and the Induction Period of the Hydrogen-Chlorine Reaction

AN investigation was commenced by us about two years ago with the view of obtaining further evidence as to the mechanism of the induction period produced in the photochemical hydrogen-chlorine reaction by the addition of small measured quantities of ammonia and other substances[1]

In preliminary experiments with ammonia it was observed that a small continuous increase of pressure of strictly zero molecular order occurred during the induction period Ammonia reacts with excess of chlorine to produce nitrogen trichloride and ammonium chloride,[2] and the observed effect is explained as a photosensitised decomposition of the nitrogen chloride by the chlorine A closely similar reaction, terminating suddenly with a semi explosive pressure change, was observed in mixtures consisting of pure chlorine and small quantities of nitrogen trichloride only, the total pressure increases obtained corresponding to the net reaction

$$2NCl_3 = N_2 + 3Cl_2$$

Quantum efficiency measurements with homogeneous light of wave lengths 366 $\mu\mu$ and 436 $\mu\mu$ indicate that the photosensitised decomposition of the nitrogen trichloride in chlorine alone, proceeds by way of re action chains of short length, the quantum efficiency falling to a limiting value in the neighbourhood of 2 as the chlorine pressure is increased 'Inert' gases, such as helium, argon, nitrogen, and oxygen, have specific retarding effects when added to the mixture, and, as the pressures are increased, finally depress the quantum efficiency towards the above limiting value of about 2

Variation of the total illuminated or unilluminated surface is without measurable effect, and it would appear that the reaction chains are initiated and con trolled in the gas phase

A further study of the induction period has shown that hydrogen has a retarding influence on the decom position of the nitrogen trichloride numerically equal to that of helium

The inhibiting effect of nitrogen trichloride on the hydrogen-chlorine reaction may be explained in the light of modern views of the negative catalysis of chain reactions, and one is led to the conclusion that small quantities of hydrogen chloride, comparable in amount with the nitrogen trichloride destroyed, should be formed during the induction period This has been con firmed Details of these investigations, together with a quantitative interpretation of results, will be pub lished elsewhere at an early date

The Band Spectrum of Silver Hydride.

ON account of difficulties in getting a convenient source of light, earlier investigations on the band spectrum of silver hydride[1] (AgH) were mainly limited to a small wave length region at λ3180 λ3480 By means of a device, I have now been able to extend these investigations to a region including a very great number of bands

The source of light is an electric arc operating in hydrogen at reduced pressure The positive electrode is made of a silver aluminium alloy The aluminium (10 per cent) has a wonderful effect on the intensity of the silver hydride bands, and in addition the troubling N_2 spectrum disappears completely. The increase of the intensity is probably due to a decrease of tem perature in the arc—the alloy chosen corresponding to the minimum points on the melting diagram of Ag-Al—an effect quite analogous to that of the high potential small current arc used previously

In this way, the rotational structure of fourteen bands belonging to the $^1\Sigma \rightarrow {}^1\Sigma$ system in silver hydride have been analysed and arranged in a vibrational scheme It appears from this scheme, that the vibrational levels of the lower electronic state can be expressed by the formula

$$F''(v) - 1723\ 5v'' - 33\ 5v''^2 - 0\ 0094v''^3$$

The excited electronic state, however, exhibits certain irregularities of spacing in its rotational and vibra tional levels, which may originate from a perturbing electronic level An approximate calculation of the dissociation energy in both states gives us

$$D' \sim 6300 \text{ cm}^{-1} \qquad D'' \sim 19000 \text{ cm}^{-1}$$

Combining these values with that of the electronic frequency of the system ($\nu_0 - 29{,}900$ cm $^{-1}$) the energy difference between both products of dissociation will correspond to a term difference of about 19,000 cm $^{-1}$, and supposing that the hydrogen atom is left unexcited, this difference should fit into the term scheme of the silver atom It might be suggested that the normal level (^2S) and the still unknown $^2D'$ correspond to these products, but strong objections could be raised to this suggestion

The investigation is now being pursued with high dispersion showing a beautiful isotope effect in the bands This and the problems already mentioned will be discussed more fully in a future paper

Properties of Dielectrics in Electric Fields

I AGREE with Mr Addenbrooke, in his letter in NATURE of Nov 22, as to the desirability of avoiding the illogical nomenclature involved in applying the term 'dielectric constant' to a quantity which is apt to vary greatly according to the prevailing con ditions

I should like to point out, however, that this matter has not been overlooked by physicists and electrical engineers

We believe that V Karapetoff[1] first urged the use of the term 'permittivity' as originally proposed by O Heaviside[2] in place of specific inductive capacity This term is now common amongst British and American electrical engineers, and is given as preferred to specific inductive capacity, dielectric constant, etc, in the "British Standard Glossary of Terms used in Electrical Engineering", published by the British Engineering Standards Association in 1926 Further, the term 'inductivity' has also been proposed

It might be of interest to point out here that according to Faraday's conception, the specific in ductive capacity of a substance is a mere number, being the ratio of two measurements, one of which is made with the substance and the other with air or the ether (vacuum) as dielectric medium In arranging the system of units so that the specific inductive capacity of the ether is unity, the quantity still remains a numeric

According to Heaviside, however, a medium must

possess two physical properties if waves are to be propagated therein, and he therefore suggested it was desirable to postulate their real existence, and admit that they are measured by the 'permittivity' and 'permeability' of the substance in question, notwithstanding that the precise physical interpretation may remain unknown.

Something similar was done in regard to atomic weights, which were referred to the weight of the hydrogen atom taken as unity, before the real existence of atoms was established.

To this extent, therefore, it may be stated that the 'permittivity' and 'permeability' of a substance measure real physical properties, though, as in the case of the atomic theory with the discovery of atomic numbers, a more fundamental property may one day be found.

Conjunctival Halos.

THE halos familiar to those who resort to swimming baths at night present a subject of some interest. They are referred to in a pamphlet published by the Ministry of Health on "The Purification of the Water of Swimming Baths" (1929), p. 18, as follows: "Owing to the difference in composition between tears and bath water, any prolonged swim causes a slight mechanical or osmotic conjunctivitis, as may readily be observed, after a long swim, by looking at a distant light by night, when the light will be seen surrounded by a halo, due to slight conjunctivitis."

There are, in fact, two spectrum-coloured halos, each with its outer edge red, thus indicating diffraction as their cause. The inner halo shows considerable dispersion. It is noteworthy that, unlike the effect seen through lycopodium-covered glass, the space immediately surrounding the source of light is dark.

The radii of the halos are easily measured by means of a 'Jacob's rod', and are found to be:

Radius of red outer edge of 2nd order halo = 8° 25′
" " " 1st order halo = 4° 49′

The second order spectrum is comparatively faint and therefore the first order value is the more trustworthy.

Inserting this in the equation $(a+b)\sin\theta = (2n+1)\frac{\lambda}{2}$, and taking the wave-length of the red light as $700\mu\mu$, we get 0.0125 mm. as the value of the 'grating interval' $(a+b)$. The second order spectrum gives the value 0.0120 mm.

It seems, therefore, that the surface of the cornea is covered with structural elements of this order of magnitude. Shelford Bidwell arrived at a similar conclusion from other evidence. The experiment described in his "Curiosities of Light and Sight" (1899), pp. 124-129, indicates the existence of elements $\frac{1}{2000}$ inch (0.0127 mm.) in length or breadth.

The refractive index of the cornea is 1.350 (Krause, in Helmholtz), and of water 1.333. This difference is evidently enough to bring the structure into sufficient relief to produce the diffraction.

Tyndall (*Phil. Mag.*, [4], vol. 11, p. 332, 1856) has described a similar effect in which the centre of the ring system is bright.

An Ostrich Shamming 'Wounded'.

THE device of pretending to be wounded in order to lure marauders from the nest is one that has been recorded in the case of a considerable number of species of ground-nesting birds, mostly belonging to the more specialised families. So far as I can recollect, it has never been observed in the case of the ostrich.

Dr. T. A. Nash, a former pupil of mine now in the service of the Government of Tanganyika, writes to me as follows:—'On Oct. 24 last I noticed a male ostrich coming straight towards me, not farther off than 50 yards. The bird trailed its wings as if they were broken, and then seeing me, started off slowly at right angles to its original direction. One wing would flap spasmodically and then the ostrich would sit down, looking backwards to see how near I was. As I approached, the bird would stagger to its feet, lumber on a few yards, and then sink down. Once it appeared to be too weak to stand up and toppled over on to its side, where it lay panting. Feeling certain that the ostrich had been mauled by a lion, I called for my rifle in order to shoot it, when one of the boys called, 'The bird is well and only acting; it must have a nest near.' Leaving one boy to watch the bird, the rest of us retraced our steps, and we found the nest about 40 yards away from where I had first seen the bird.

'The 'nest' simply consisted of a clearing in the grass, with eight young birds sitting on the powdered black earth amidst broken egg-shells. Other young had scuttled off into the long grass. In addition, there was one egg in the nest. Without touching anything, we concealed ourselves at some distance off. Almost immediately we saw the male trotting back in perfect health, accompanied by the female. The female must have been at some distance off, feeding, the male being left to look after the nest—and very well he did it.'

It is interesting to find such intelligent behaviour in so primitive a bird as the ostrich.

Letter from Charles Darwin to Lord Farrer.

I SEND herewith a copy of a letter to the late Lord Farrer from my father, Charles Darwin. So far as I can ascertain, it has never been published. It was evidently dictated, probably in the afternoon when tired by his morning's work. His remarks on observation and reasoning seem to me to be of especial interest. A letter on the same subject, definitely admitting his error, is given in "More Letters", vol. 2, p. 373.

"May 19, 1868.

"Many thanks for your notes. I do not doubt that you are right and I wrong. How I came to make such a blunder I do not know, for I examined the flowers repeatedly. I suppose I reasoned from the shape of the caudicle, and it is a fatal fault to reason whilst observing, though so necessary beforehand and so useful afterwards. I will try to find a specimen to convict myself. I wish you or someone could find out what insects visit the fly ophrys and for what purpose. I am delighted to hear that you are interested about the structure of orchids. I was formerly quite fascinated with these plants, especially with O. Pyramidalis and the common listera."

Stellar Structure and the Origin of Stellar Energy *

By Prof E A MILNE, F R S

PERHAPS the most striking general characteristic of the stars is that they can be divided into two groups of widely differing densities In the first group, which comprises the majority of the known stars, the densities are of 'terrestrial' order of magnitude, that is to say, their mean densities are of the order of the known densities of gases, liquids, and solids They range from one-millionth of that of water to ten or, in rare cases, perhaps fifty times that of water In the second group the densities are of the order of 100,000 times that of water Of the second group, the 'white dwarfs', only a few examples are known, but they are all near by stars, and it is generally agreed that they must be of very frequent occurrence in Nature, though difficult of discovery owing to their faintness Whether stars exist of intermediate density remains for future observation The possibility of the existence of matter in this dense state offers no difficulty As pointed out by Eddington, we simply have to suppose the atoms ionised down to free electrons and bare nuclei At these high densities the matter will form a degenerate gas, as first pointed out by R H Fowler But this leaves entirely unsolved the question of why, under stellar conditions, matter sometimes takes up the 'normal' density and sometimes the high density Owing to the probable great frequency of occurrence of dense stars, it might reasonably be asked of any theory of stellar constitution that it should account for dense stars in an unforced way

There are two main theories of stellar structure at the present moment That of Sir James Jeans accounts for the existence of giants, dwarfs, and white dwarfs, but only at the cost of *ad hoc* hypotheses quite outside physics It assumes stars to contain atoms of atomic weight higher than that observed on earth, and it assumes them to be relentlessly disappearing in the form of radiation, it appeals to discontinuous changes of state consequent on successive ionisations, for which there is little warrant I think it is true to say that the majority of astronomers do not accept this theory

The theory of Sir Arthur Eddington does not claim to account for the observed division of stars into dense stars and stars of ordinary density, nor does it establish the division of ordinary stars into giants and dwarfs On the other hand, it claims to establish what is known as the mass luminosity law from considerations of equilibrium only, that is, without introducing anything connected with the physics of the generation of energy It claims to show that the observed fact that the brighter stars are the more massive can be deduced from the conditions expressing that the star is in a steady state, mechanically and thermally It does this by making the hypothesis that the stars (giants and ordinary dwarfs) consist of perfect gas Closer consideration of the actual formulæ used by the theory shows that it scarcely bears out the claims made for it by its originator The 'formula for the luminosity' of a star makes the luminosity very nearly proportional to its effective temperature, and so the so-called proof of the mass luminosity law involves a semi-empirical element, namely, an appeal to the observed effective temperatures of the stars, for the observed values of which the theory *fails to account* Another difficulty encountered by the theory is that it makes the interiors of the more luminous (giant) stars cooler than those of the fainter stars, and it makes the interiors of both too cool for the temperature to have any appreciable influence on the rate of generation of energy, by stimulating, for example, the production of radioactive elements or the conversion of matter to radiation

The claim to establish the mass-luminosity law from mere equilibrium considerations cannot, however, be sustained for a moment We may regard a star in a steady state as a system provided with an internal heating apparatus (the source of energy) It adjusts itself—state of aggregation, density distribution, temperature distribution—until the surface emission equals the internal generation of energy L But provided the luminosity L is not too large (in order that the mass shall not burst under radiation pressure), it is clear that a given mass M can adjust itself to suit any arbitrary value of L If, starting with one steady state, we then alter L (upwards or downwards) by altering the rate of supply of energy, the star will simply heat up or cool down until the surface emission is equal to the new volume of L—precisely like an electric fire L and M are thus independent variables so far as steady-state considerations are concerned The fact that L and M show a degree of correlation in Nature must be connected with facts of an altogether different order, namely, with the physics of energy generation It is essential to recognise the difference between the formal independence of L and M as regards steady-state considerations and the observed correlation of L with M in Nature The observed mass luminosity law must depend on the circumstance that in some way the more massive star contrives to provide itself with a stronger set of sources The claim to establish the mass luminosity law from equilibrium considerations only appears to me a philosophical blunder Further, it is unphilosophical to *assume* the interior of a gas to be a perfect gas, either knowledge of the interior is for ever unattainable or we should be able to infer it from the observable outer layers

When we dispense with the perfect gas hypothesis and at the same time recognise the independence of L and M as regards steady-state considerations, it is found that a rational analysis of stellar structure automatically accounts for the existence of dense stars without special hypothesis Further, it shows, as common sense would lead us to expect, that the more luminous stars must have

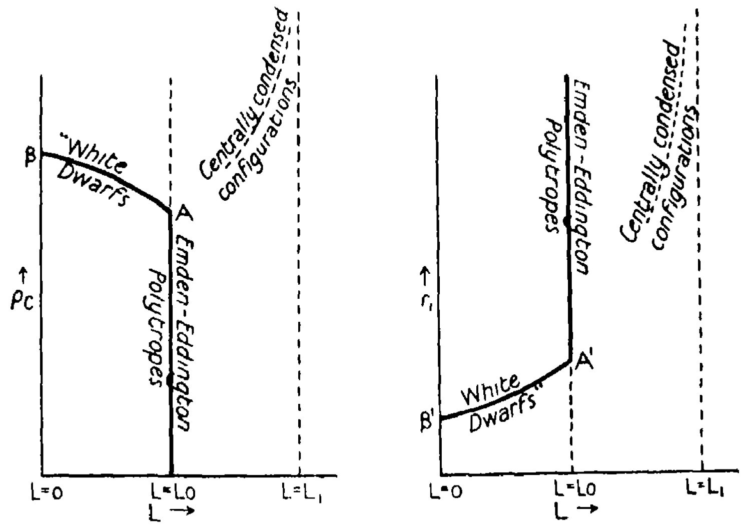
* Substance of lectures delivered at the Royal Institution on Dec 2 and Dec 9, 1930

the hotter interiors Here the temperatures are found to range up to 10^{10} degrees or higher, depending on luminosity—a temperature sufficient to stimulate the conversion of matter into radiation In addition, it shows that the central regions of stars must be very dense, ranging up to 10^7 grams cm $^{-3}$ or higher Thus the difficulties met by earlier theories fall away as soon as the ground is cleared philosophically

The foregoing ideas suggest the following as the fundamental problems of stellar structure (1) What are the configurations of equilibrium of a prescribed mass M as its luminosity L ranges from 0 upwards, M remaining constant ? (2) What is the effective temperature T_e associated with a given pair (M, L) in a steady state ? (3) What is the value of L which will actually occur for the physical conditions disclosed by the answer to problem (1) ?

We observe that the outer parts of a star are gaseous Consequently we can solve the problem of the state of any actual star by integrating the equations of equilibrium *from the boundary inwards*, we are entitled to assume the gas laws to go on holding until we find that the conditions are incompatible with them We then change to a new equation of state, and carry on as before We change our equation of state as often as may be necessary until we arrive at the centre

The answer to the first of the problems formulated above has been worked out, for certain types of source distribution and opacity, by the method of inward integration The results are sufficiently alike to be taken as affording insight into the nature of stellar structure in general, and are as follows For a given mass M, of prescribed opacity, there exist two critical luminosities L_1 and L_0 $(L_1 > L_0)$ such that for $L > L_1$ no configurations of equilibrium exist, for $L_1 > L > L_0$ the density and temperature increase very rapidly as the centre is approached $\left(T \propto r^{-1}\left(\log \frac{\text{const}}{r}\right)^{-\frac{1}{4}}\right)$, so that in the centre there is a region of very high temperatures and densities where the gas laws are violated, for $L = L_0$ a diffuse perfect gas configuration is possible, for $L_0 > L > 0$ the only perfect gas configuration is a hollow shell provided with an internal, rigid supporting surface of spherical shape Since in Nature no internal supporting surface is provided, to find the actual configuration when $L_0 > L > 0$ we construct the artificially supported hollow configuration and then remove the supporting surface The mass must collapse, and collapse will proceed until a steady-state is attained in which, except for a gaseous outer fringe, the gas laws are violated Such configurations may be termed 'collapsed' Configurations for which $L_1 > L > L_0$ may be termed 'centrally-condensed' The physical origin of the different types of configuration is simply the varying effect of light pressure For $L = L_0$ the light-pressure due to L is just sufficient to distend the star against its self gravity and maintain it in the form of a perfect gas For $L_1 > L > L_0$ light-pressure is so high that for equilibrium to be maintained gravity at any given distance from the centre must be assisted by concentrating as much matter as possible inside the sphere in question, when this process is carried out for all spheres, we get a central condensation For $L_0 > L > 0$, light pressure due to L is so low that the mass cannot support itself against its own weight in the form of perfect gas, and collapse sets in until the gas laws are disobeyed The diffuse configurations $L = L_0$ are unstable with respect to small changes of L



FIGS 1 and 2 —The linear series of steady state configurations of a mass M, of prescribed opacity, as its luminosity L varies (The white dwarfs are the collapsed configurations of the general theory The Emden Eddington polytropes are the gaseous diffuse configurations of the general theory they are unstable in general with regard to deviations of L on either side of the value L_0 The centrally condensed series has not been fully worked out—it awaits the construction of certain tables—but it may be provisionally identified with stars in the state of giants and ordinary dwarfs The diagram is to be understood as classificatory not evolutionary) (ρ_c = central density r_1 = external radius)

For collapsed or centrally condensed configurations the centre will be occupied by a gas in a degenerate state When the mean densities or effective temperatures of collapsed configurations are calculated, using the Fermi Dirac statistics for the degenerate gas, they are found to agree with the observed order of magnitude for white dwarfs Thus, collapsed configurations may be identified with white dwarfs A white dwarf is thus a dense star simply because its luminosity is too low, and its light pressure accordingly too low, for it to support its own mass against its own gravity From another point of view the calculation affords an observational verification of the numerical value of the 'degenerate gas constant' the coefficient K in the degenerate gas law $p = K\rho^{5/3}$, and so a check on the Fermi Dirac statistics

If collapsed configurations may be identified with white dwarfs, centrally condensed configurations

may be provisionally identified with ordinary giants and dwarfs, though the full determination of the properties of centrally-condensed configurations awaits the construction of certain tables Centrally-condensed configurations appear to have the properties that as L decreases from L_1 to L_0 the effective temperature rises to a maximum and then decreases again This would correspond to the observed division into giants and dwarfs I give this deduction with some caution, as it is not yet demonstrated rigorously in the absence of the tables above mentioned

A point not yet settled is the question of the continuity of the series of centrally condensed configurations with the collapsed configurations (Figs 1 and 2) There are indications that as L passes through L_0 *from above to below, the external radius* of the configuration may decrease discontinuously, the gaseous envelope collapsing on to the dense core If this is confirmed, it would follow that a star, when its steady state luminosity L falls through a certain critical value (depending on its mass), exhibits the phenomena of a nova or temporary star For it would have to disengage a large amount of gravitational potential energy in a short time, so that the actual emission would undergo a temporary increase, falling again to a value just below its previous value It would be highly interesting to have observational data as to the densities of a nova before and after the outburst The early type spectrum of the later stage of a nova may indeed be taken to indicate a high effective temperature, and so a small radius and high density, in accordance with our prediction

The important point about all the foregoing analysis is that it involves at no stage any special properties of matter or special assumptions The observed features of the stars are thus found to depend only on the most general properties of matter in association with light pressure

A question logically distinct from these is the origin of stellar energy Here we require to know something of the physics of energy generation The following suggestions are frankly of a speculative character Let us assume, in accordance with a hypothesis first made by Jeans (not his later hypothesis of super radioactive atoms), that protons and electrons can unite to form radiation Then thermodynamic considerations show that the process must be *reversible*—*photons can generate* matter We know that matter at ordinary temperatures is stable Hence we may postulate the existence of a critical temperature above which the process can go on in either direction Suppose this critical temperature has been passed at 10^{11} degrees Calculation then shows that at 10^{11} degrees almost the whole of the *mass* in an *enclosure* would be in the form of radiation, and further, that lowering of the temperature of the enclosure would result in more of the surviving matter present disappearing in the form of radiation The process is in fact the thermodynamic opposite of evaporation steam condenses to water with emission of energy, and the process is accordingly encouraged by cooling, matter 'evaporates' (to radiation) with emission of energy, and the process is encouraged by cooling Now, the centre of a star is a sort of thermodynamic enclosure with a slight leak It follows that if (as the steady state theory indicates) the central region of a fairly luminous star is at a temperature of 10^{11} degrees and a high density, then this central region is effectively a reservoir of very dense radiant energy, with a mere sprinkling of ordinary matter present Natural cooling of this reservoir provides the star's emission to space, and the reservoir is itself maintained by the conversion of matter into radiation inside it and on its confines

Calculations based on this idea are consistent with the usually accepted evolutionary time scale, and predict a rate of 'generation' of energy ϵ per gram of the right order, namely, $\epsilon = -\frac{4c^2}{T}\frac{dT}{dt}$ throughout the mass of the core, where $-dT/dt$ is the rate of cooling The rate of loss of mass is given by the usual formula $\frac{dM}{dt} = -\frac{L}{c^2}$ By combination of these formulæ it is found possible in principle to establish a relation linking M with T_c (the central temperature), *this is the additional relation which, by* expression of T_c in terms of L and M by means of the steady state theory, must lead in due course to a mass luminosity correlation Whether it agrees with the observed mass luminosity law remains for future investigation, but it is a final satisfaction that, after first considering L and M as independent variables, we are able to use the equilibrium configurations thus disclosed to arrive in outline at a solution of the problem of the actual correlation of mass and luminosity in Nature It is to be noted that the star's generation of energy is naturally non explosive, for it is simply a consequence of the natural tendency of the star to cool The star behaves, in fact, simply like a freely cooling body containing a central region of very high specific heat—namely, a pool of intense radiant energy, which is gradually drained away though partially reinforced by the conversion of matter From this point of view, it is not that a star descends an evolutionary path because its rate of generation of energy slackens, it is rather that the act of evolving and the act of radiating energy are identical

These suggestions as to the origin of stellar energy and the mode of stellar evolution are not to be pressed They are to be sharply distinguished from the steady state theory, which by the rational process of proceeding from the known stellar exterior step by step into the unknown interior indicates an inevitable series of configurations which correspond to the observed bifurcation of celestial objects into 'ordinary' stars and 'dense' stars

NOTE —The fundamental result of the rational method of analysis of stellar structure described in the foregoing article is the division of configurations into two types, the 'collapsed' and the 'centrally condensed' The existence of these two types can be demonstrated without complicated mathematics by the following argument Let r_1

Supplement to NATURE

No 3192 JANUARY 3, 1931

Biology in Education and Human Life *

By Prof A V Hill, F R S

DURING the last quarter of a century it has gradually been realised that biological science, no less than physical science, has an important rôle to play in the affairs of human life Man is a creature partly of his inheritance (which we are just beginning to understand), partly of his environment and education (which have long been matters of study and discussion) His nature, as a sensitive, responsive, and creative being, is determined partly by the material—in a wide biological sense—of which he is constructed, partly by the treatment to which—in development and education—that material has been subjected

Human Nature and Environment

I would not deny—far from it—the extreme importance of the environment of the traditions, of the stores of wealth and knowledge, of the accumulations of wisdom, wit, and loving kindness which surround us Do not imagine that experimental science leads necessarily to materialism in those who follow it Like Martha, indeed, we are often cumbered about much serving in our laboratories we have to be careful and troubled about many things—including the working of our apparatus which leaves us often, alas, with too little time for reading or reflection Those of you however, who, like Mary, have chosen the good part, do not be too sure that we poor experimental scientists are entirely lacking in appreciation of the more spiritual affairs It is only when provoked by theological dogma, or by prejudice blinding people's eyes to the most evident facts, that we lose our heads and tempers and become breakers of idols Naturally, I think, we are sane and reasonable people, people who if treated with a little kindness and understanding may often be made quite decent members of society Admitting however, the value of the accumulated wealth and wisdom in our environment, of the culture stored by centuries of thought and labour, the hard facts of experience and experiment tell us certain things, which cannot be denied, as to the biological background of our human nature These things, of which so many educated people are quite, or almost, unaware, are what I wish to discuss here

Each of us arose from the union of two cells, one of which alone decided the sex to which we belong Our inheritance of bodily characteristics and of mental tendencies was determined by certain elements in those cells, elements the separate existence of which is as certain as that of atoms and electrons Our bodies and our nervous systems developed in a certain way, affected—but not settled—by our environment, through the continual division of those cells The finished product—ourselves—depends for its proper functioning upon a variety of measurable factors, internal and external to the body Our children inherit the same tendencies and possibilities visible or latent, as we do, masked or exaggerated by the tendencies and possibilities of their other parents Health and happiness, power to contribute to the common stock, are linked as functions of the many variables of inheritance and surroundings The peculiarities of brain and nervous system, of internal secretions and digestion, are mingled with education and environment, with poetry and religion, in producing mind and character Great, therefore, as are our birthrights of environment, vast as are the unconscious effects of tradition and upbringing, we delude ourselves if we do not recognise that the nature of man the individual, and of mankind the organised society, depends in large measure on biological factors

The General Ignorance of Biology

It is easy to be too ignorant of these elementary facts it is possible for grown up men and women, otherwise educated people, to be wholly unaware of all that pertains to the science of living things Even among scientific men themselves, many are quite innocent of any acquaintance with that major half of natural knowledge which comes under the category of biology What would they say of a biological colleague who knew nothing of elementary

* Being the Henry Sidgwick Memorial Lecture delivered at Newnham College Cambridge on Nov 22

algebra, who could not use simple physical apparatus, who had never learnt to employ a balance, who could not tell the difference between momentum and energy? So great indeed is their innocence that many of them suppose the problems of biology to be quite simple, only rather messy and inexact! How many historians, scholars, lawyers, even philosophers, have any biological knowledge? Yet what would they think of a biologist who was completely ignorant of history, literature, or philosophy, who could not read a single foreign language? It would seem, however, that to be unversed in matters so important as those with which biology deals, and withal of such supreme interest, is no less to be deplored than to be quite unlearned in humane letters.

It is possible in the University of Cambridge to obtain an honours degree in science by taking the Natural Sciences Tripos and studying only physics, chemistry, and mathematics. It would be equally possible to take three biological subjects, but these would necessitate at least a certain knowledge of chemistry and physics. No man or woman, I feel, should be able to go out from this place with the hall mark of a scientist who has not taken, here or at school, some course in general biology. Many unfortunates, gifted with no power of solving equations or of conjuring with triangles, struggle for years in attempting to pass the mathematical examination for matriculation in various universities: and yet there is no requirement at all of knowledge far more fundamental to human life than mathematics. Latin our children must take in the 'Little Go': Latin is essential to the proper understanding of literature: biology only to the proper understanding of man! Mathematics and Latin are an excellent discipline for the mind: granted for those who have that kind of mind. But would you teach them these to the exclusion of all more natural knowledge? Would our colleagues in those subjects, often knowing nothing of biology, dare to assert that there is no mental discipline to be found in the study of life phenomena? Few discoveries are of such general significance, such universal application, not many facts have had such an effect on human thought in all its aspects, as that of evolution. Are the implications of evolution of less significance than those of the binomial theorem or of Latin grammar?

Economics deals with human life, with man in his social aspects; it cannot fail to be concerned with problems of population, food supply and transport, public health, heredity, eugenics, psychology, and medicine: all matters of great significance involving, if they are to be properly understood, the biological factor. How many economists have any acquaintance with biology? Admitting the value and importance of history as a factor in political economy, admitting the mental discipline of the classics and (for the sake of argument) the greater grace and dignity of the writings of those who have been brought up on Greek and Latin; admitting that mathematics enables the student to think in terms of flux and change, and is bound to aid in a study involving probability and the laws of large numbers of differing individuals: admitting all these things, is there no place for biology in a scheme of teaching and research in economics? I do not imply that economists should be experimental biologists. We teach physics and chemistry to our medical students, not because we expect most of them to use these sciences in their practice—they certainly will not—but as a necessary discipline and preparation for their minds. To exclude physics and chemistry from medicine would seem just as reasonable as to omit biology from political economy.

Biology in Relation to other Science

One difficulty in the teaching of biological science arises from the fact that this requires a knowledge of other things: of chemistry and physics, of a certain minimum of mathematics. It is possible for a mathematician, a physicist, or a chemist to be unaware of most that lies outside his proper study. Such narrowness is rarely found in a biologist: his work requires at least a nodding acquaintance with the other sciences. Except to the pure naturalist, and often indeed to him, the phenomena of life are bound to raise questions of chemistry and physics, or of meteorology and geography, at every turn. The coefficient of thermal expansion of water, for example, and its variation with temperature, determine the relative richness of cold and tropical regions in living fauna. Currents and climate, temperature and radiation, the constitution of the land, the composition of the air, these determine the incidence and possibilities of life. The concentrations of phosphate and nitrate in sea water are limiting factors in the amount of its living material; solar radiation acting on the plankton determines the great growth of spring and early summer. The presence of carbon dioxide in the air, of iodine, calcium, and oxygen in the streams: such factors, and an infinite variety of others, provide a necessary basis for any discussion of the natural habits and development of animals and plants.

Often enough the physical and chemical questions provided by life are very complex and difficult, requiring special training and experience for their solution. Herein, indeed lies the difficulty, not only in teaching biology, but also in tempting the ablest minds to take it up as a profession.

This difficulty can be solved only by a compromise. In its elementary stages the study of biology provides little of the discipline which we associate with mathematics, or with Latin and Greek. There is no *pons asinorum*: there are no things peculiarly difficult to understand; there are no problems to solve, no examples to set, no proses to translate, no poems to juggle into hexameters. The mind, like the body, can only be trained to its best performance by setting it to do what is hard, in facing and overcoming difficulties, in making efforts not merely of repetition but also of achievement. Elementary biology provides little of the mental gymnastics which we associate with these older studies. Moreover, in all but its simpler stages, biology requires a knowledge of other sciences: without these large fields of it are meaningless. The tendency, therefore, and in principle a good one, is to teach those other sciences first. Unless, however, we are prepared to tolerate a degree of specialisation in our schools which is undesirable both for education and for science itself, there is little time or opportunity left for still another scientific subject. Biology in consequence is left to take a second place—or no place at all—at school. The best minds of the coming generation are steeped in mathematics and physical science—if in any science—and it is difficult later to draw them off into biology.

Recruits to Biology

In the past the recruits to physiology and other biological subjects came largely from those who had studied classics and mathematics in their earlier days and then decided to devote themselves to natural science. The Science Tripos at Cambridge—as it was—had a great advantage in this respect, by leading many of the ablest students to study one at least of the biological subjects. The possibility of taking mathematics, as well as physics and chemistry, has largely closed that channel. I am sufficient of a reactionary to feel some of the advantages of the older traditional type of education. The practical difficulty has arisen owing to the much more widespread teaching of science at school. In previous days we came to a university with our minds open, and if we decided to study science we chose our subjects without prejudice. By the time, nowadays, that a student has spent at school some years already at one subject, he is unlikely to be so reckless as to burn his boats and transfer his allegiance elsewhere. Moreover, there is such a demand by their teachers for men and women of the highest ability, that every possible inducement is offered them, if they be able enough, to remain where they are.

I know that my mathematical and physical friends would be deeply grieved — and quite rightly, from their own point of view—were we biologists able to tap the source of their ablest students. Our problems, however, are at least as important, at least as interesting, and far more difficult than theirs, and I have no doubt at all that many of the ablest workers in our universities who now devote themselves to mathematics, physics, and chemistry would have made, had they been caught early, equally distinguished biologists. I am sure, indeed, that many of our classical or legal friends, had they been given the chance, would have done at least the same: they are not so incompetent either! As a practical step, biology must demand that, with all its intellectual interest and its importance in human affairs, it should be brought sufficiently to the attention of boys and girls to enable them to decide with their eyes open whether that, or something else, is what they wish to study. The quality of our recruits would rise, could time be found in the last few years of school to introduce, in a general way, the ideas and possibilities of biological science. Those should be regarded as lacking education who are altogether ignorant of the nature of living things.

Biology an Essential Factor in Education

The discipline of the mind, important as it is, is not the only object in education, any more than is the production of athletic champions the chief purpose of physical training. Many of the subjects taught at school—history, geography, modern languages, poetry, divinity, music—are to be regarded rather from the point of view of their cultural value than as simple mental gymnastics. Experience has shown that biology also can be included in this larger category, even for children of a relatively tender age. An admirable pamphlet, "Biology in the Elementary Schools and its Contribution to Sex Education", published by the American Social Hygiene Association, describes a series of experiments in the teaching of biology, even to quite young children, by a group

of sympathetic and intelligent people "To children in general, regardless of their upbringing, the world of living nature is vastly interesting" "Children have shown in the course of their studies in biology ample evidence of their ability to classify facts, recognise relations between ideas, make generalisations, formulate results" "They have found new problems in old haunts, have examined them resourcefully, critically, objectively" It is true that such teaching requires more skill and understanding, more forethought and preparation than much of the established routine of the schools Biology poorly taught is as bad as history poorly taught To introduce biology wholesale, and without the provision of intelligent and sympathetic teachers, might be dangerous and would certainly lower its value as an ingredient in a humane and liberal education Let us retain without question the subjects which discipline the mind by their formal precision, their logical difficulties but among those which are taught in order to breed a wider understanding of the world, I would urge that, in the ideal school, biology in its general aspects should have an assured and honourable place That place, however, must be acquired gradually

In a variety of ways such a minimum of biological knowledge as I would have every child possess can minister to his or her needs and thoughts and difficulties The problems of sex are much simpler if seen from the natural and objective point of view Reproduction is an honest and straightforward matter from the biological aspect Inborn differences in mental and physical qualities, and the manner of their origin, are essential factors in the structure of society our views of human relationships are bound to be affected by the existence of such differences—and to breed rational views on human relationships is one chief purpose of education The basis of the family or the tribe, the relative effects of inheritance and environment, the aristocratic or the democratic principles in government, all these are matters which lively young minds will ponder and debate, and which ultimately depend upon the intrinsic properties of man, the biological unit Problems of mental and bodily health, of nutrition, of physical training, of disease, belonging naturally in one sense to medicine, are most readily approached by children, as by adults, through the channel of biology

It is possible, of course, to trade on ignorance, for selfish and even for unselfish ends Those who believe in war may object to enlightened education on matters pertaining to reproduction as likely to diminish the supply of 'cannon fodder' Those who desire to maintain the rights of inherited power, or rank, or wealth, may prefer to uphold the biological fallacy underlying an aristocratic constitution of society Those who look to socialism as a cure for human ills may try to disguise the fact that all individuals are not, and cannot conceivably be made, alike in quality or character To all, however, who desire to know and to spread the truth in such matters, trusting in the good sense of mankind, there can be no question that if the claims of biology are verified, it is right to demand for it a proper place in education

Inheritance and Eugenics

Can the claims of biology be verified? I will give a few examples Let us take first the subject of inheritance, and assume (for the sake of argument and simplicity) the gene theory of its mechanism In recent years, owing to careful experimental studies, the manner in which natural characteristics are inherited or handed on has become apparent, if not in detail, at least in general outline There are many common fallacies about inheritance, derived from imperfect experimental knowledge or by false deduction from experience Much of so called eugenics is based upon such fallacies It is often imagined, for example, that by preventing the breeding of feeble minded individuals the race might in a few generations be completely relieved of the burden of feeble mindedness Assuming (to quote Jennings) that the feeble minded make up about one third of one per cent of the population, it is possible to compute that about ten per cent of the population bear *one* of the defective genes, a pair of which lead to the defect in question In a population of 50 millions there is a group of 45 millions having none of the defective genes at all, another group of 5 millions, quite normal minded but with one defective gene, people whom we may describe as carriers of feeble-mindedness, the defect being latent but ready to appear in the offspring if combined with a similar one from the other parent, and a minor group of 160,000 actual feeble minded, carrying two defective genes If both the second and the third groups together could be prevented from breeding, feeble mindedness could be eliminated in a single generation This, however, in our present state of knowledge, is quite an impossible achievement, there is no way of recognising a defective recessive gene except in its occasional effect on the offspring If we could prevent—and to this there are merely the usual sentimental objections—

the breeding only of the third group, the actual feeble-minded, we should get rid at once of about 11 per cent of these defective people in the next generation

The procedure, however, of eliminating this 11 per cent would have affected very little the reservoir of carriers, the five million just mentioned Repeated in the next generation it would have comparatively little additional effect, and would need to be continued indefinitely to maintain even the ground gained I am not saying that this should not be done—it *should* be done, but we must not expect too much from it It has been computed that if a character governed by these rules affected one per thousand of the population, and if we attempted to eliminate it by preventing the propagation of those who possess its two defective genes, it would require 68 generations (or 2000-3000 years) to reduce its incidence to 1 in 10,000 Two morals may be drawn (1) that eugenic hindrance to breeding, with the knowledge we now possess, might produce a definite but not a startling effect in bettering the race, and (2) that research in such matters should be pressed on, for if we could find the means of recognising latent defective genes in those who carry them, we should have forged a tool which, in a single generation if men would submit to its use, would relieve mankind for ever, or at least until they arose spontaneously again, of some of the scourges of the race

Mankind, in all probability, has many millions of years yet to run before forces quite outside our control finally render the earth unfit for habitation Anything which we can do, by rearing a fitter race of men, to make the future happier and richer would seem to be well done Some qualities are obviously more desirable than others There exist human beings who are vigorous, wise, virtuous others that are not, the differences depend in part upon inheritance Could we eliminate the tendencies not only to undesirable mental qualities but also to harmful physical ones—susceptibility to disease such as cancer and tuberculosis, deformities, various forms of weakness and unfitness—how happy and how beautiful a race might yet reign upon the earth Look, as Jennings says in his book, "The Biological Basis of Human Nature", on what has been done for the breeds of cattle and poultry and for cultivated plants Shall we use, it is often asked, our knowledge of genetics for the improvement of domestic animals and fruits, and neglect the infinitely more important improvement of the human stock? This is the question which eugenists ask The answer—to some a very unexpected one—can readily be given, loosely quoting Jennings's words

"There is no obstacle in the known principles of genetic science to the attainment of such a result, provided we can decide on the qualities we wish to preserve or promote in our human stock, and provided that the necessary methods are applied with the necessary thoroughness for the necessary length of time The difficulties are not in the theory but in the practice A practical breeder must be placed in complete control with instructions to fear not God neither regard man in the execution of his project He will mate a few individuals possessing characteristics as near the desired ones as he can find, and he will stop the propagation of the rest Then he will proceed to bring to light the defective genes by reversing the rule of family eugenics, that is the canons against inbreeding The selected progeny of his first cross will be inbred, as cattle are inbred This will bring together, on the one hand, defective genes, on the other, desirable genes, the results will appear in the personal characteristics of the individuals produced A great stock of defective and deformed individuals will appear along with a number that are not defective or are less defective Those showing undesirable traits will again be eliminated, the rest again inbred By a continuation of this process, with at times judicious crossing of superior individuals followed by further inbreeding and elimination, the defective and undesirable genes will gradually be uncovered and removed from the race In this way after many generations a race will have been produced all of whose individuals show the combination of characteristics sought a combination of the highest characteristics found in man (so far as none of these are incompatible with the others) The obstacles to the production of this result lie not in the theory of the matter but in its practice Obviously, however, the practical obstacles are insuperable"

Mankind would not submit to the tyranny required This type of eugenics, based upon the analogy of the domestic animals, does not lie within the bounds of practicality

Applications of Biology

The first and perhaps the most dramatic applications of modern biology have been in the prevention of disease Pasteur followed up his demonstration that spontaneous generation does not occur, with the discovery that infectious diseases, such as typhoid, diphtheria, and pneumonia, are caused by living organisms Most of these are bacteria many of the rest, like those of measles, are too small to be seen Others are of an animal nature, like the active causes of malaria and sleeping sickness Together with such discoveries arose the science of parasitology The life histories of various parasites were

unravelled, with the result that it has been possible in many cases to stamp out the corresponding disease or affection Frequently there is an association between some parasite or animal and the microscopic agent of some disease Anti typhoid inoculation, the control of diphtheria, the elimination of malaria over wide areas of the earth—these have been some practical consequences of such work No longer do we think of disease as due to evil spirits, or as magic sent by God for our punishment In such matters biology has certainly produced a very evident effect

In the economic fields of agriculture, forestry, and cattle raising the study of parasites and of the organisms of disease has proved no less important Throughout the British Dominions to day there is urgent need for zoologists and botanists, young men of enterprise and scientific training, to aid in solving important practical problems The demand is far greater than the supply At the present time, at Plymouth, a certain degree of success seems already within range in predicting the quality and the approximate locality of herring fisheries from year to year Water supply and sanitation require biological knowledge, bacteriological technique The transport of living fruit from the ends of the earth is a joint problem of *biology and engineering The freezing of meat*, the drying of milk, the preservation of eggs, the canning of fish, the safeguarding of vitamins in food, the standardising of drugs, all such matters implicitly assume a certain biological knowledge These are not unimportant things in human life Constructing Latin verse or studying Greek philosophy may be better gymnastics for the mind, but even Cabinet ministers and leader writers might find a little biology useful for an understanding of the world

It is not necessary to insist upon the close relation between physiology and medicine, the oldest almost of all sciences and arts No man has served medicine better than William Harvey, who by the vivisection, as he says, ' of toads, serpents, house snails, shrimps, crevisses, and all manner of little fishes ", together with a host of other animals, discovered the circulation of the blood—the greatest single discovery in the whole of medicine From his day downwards along the years the services of physiology to medicine, and to the alleviation of human disability and suffering, have accumulated Not many of us are doctors, but most of us from time to time are patients To understand even a little of what medicine means, of the general principles upon which it is based, to regard ourselves objectively, when we are sick, as an experiment, to think of public health, of medicine, and of surgery in concrete terms instead of as a form of magic surely if an elementary knowledge of biology can secure these things—and I think it can—it deserves a better place in our curricula Perhaps the most important service of biology is to give men a reasonable attitude towards life

Psychology

These are practical affairs In universities, however, and in schools, we study things not merely because they are practical but chiefly because they are interesting things that are interesting will be practical enough in good time In most branches of learning, we have to weigh the value of human evidence Evidence, as we know, is coloured by emotions and desires few, however, realise how often or how much Why is it that one person, or one group, inevitably draws one type of conclusion from the evidence, another draws a different? In our conscious minds we are honest, or we try to be honest, enough why, however, do we reach different conclusions from the same apparent facts? In historical matters we must often ask whether it is *not more probable that human senses were deceived*, that human judgments were at fault, than that such and such a thing ever happened at all In records of miraculous cures and of wonders of all kinds, in the tales of witnesses of accidents in ordinary life, we know how our opinion of the value of evidence must always be tinged with a certain scepticism The senses of man may be deceived, his sensations may be misunderstood or misinterpreted, his judgment—especially after the event—may be distorted by what he wishes, or thinks he ought, to believe

These are matters of human psychology and behaviour and psychology is based upon the physiology of the senses and the brain Those who have no idea of the mechanism of sensation, who believe in the absolute existence of all they see or hear or feel, who do not realise that these are simply judgments, summaries, pictures in the nervous system, of millions of nerve messages received from their peripheral sensory organs, are all too ready to be led astray into false judgments of fact Thus arise beliefs in the existence of things that do not exist at all, outside our own sensations Common superstitions, magic, spirit photographs, premonitions, all the incredible things we read even to this day in the daily Press

about omens or curses or bad luck—these would vanish into thin air were the evidence to be examined objectively in the light of what is known of the fallibility of human senses and judgment I have often thought that a university should have a professor of conjuring to demonstrate how easily we can be deceived and a reader in mental disorder to convince us how much our judgments, even of matters of fact, may be affected by our expectations, our state of health, our emotions, our desires

Psychology, to the degree that it has an objective basis, is founded upon observation and experiment on animals and men 'Behaviourism' may not be so important as some of its advocates claim conditioned reflexes may not be the origin of all our actions, as certain enthusiasts maintain psycho-analysis may invent, as well as discover, the hidden causes of our mental states Other sciences also have made grave mistakes in their youth Which among them shall first cast a stone at psychology? How often has physics discovered a complete formula for the universe? How often has the mystery of life been solved? Based, however, on the physiology of sensation, on the objective study of reflex and cerebral activity, on observation of the behaviour and development of animals and men, on the analysis of instinctive actions and intelligent reactions based on these there can be no doubt of the importance, or of the future growth, of psychology Psychology is a biological science—biological in its widest sense—and it has great gifts to bring to the other branches of human knowledge in allowing us to appreciate and understand men's motives, men's instincts, men's behaviour as individuals or in larger groups, and the various disturbances which affect their minds and conduct

We can take a more charitable view of apparently perverse behaviour if we realise that abnormal mental states are relatively common, and that desires and emotions, feelings and memories, underlie all human conduct We shall be more likely to be reasonable ourselves if we recognise the imperfections of our cerebral machinery, if we appreciate our own motives, if we understand—which is not at all easy—the origins of our actions The most humane approach to the study of human conduct, I would urge, is one which takes due account of the biological factors in humanity

Progress by Experiment

Biology in the present stage of its development is inevitably concerned with practical experiment it has not yet attained the precision of knowledge at which theoretical treatment of its problems is often of significance Physics, on the other hand, in its philosophical implications, is stretching out far into the unknown its mathematical aspects are occupying the attention of some of the greatest intellects of the age It is possible for a man to make the most important contribution to physical science, although himself quite unskilled and unversed in experiment or observation This is not yet possible in biology, nor will it be for many years to come Biological material is so much more complex, so much more difficult to fit to a decisive experiment, the number of its variables is so much greater We have to deal with an almost infinite variety of mechanisms, confined in a single living cell which may lie almost on the limits of visibility

Reflect, for example, on what our inheritance means We are in the first place human beings, not onions or elephants then perhaps we are white human beings, with red hair, blue eyes, and freckles we have physical, mental, emotional, and moral characters of all kinds we hand these on in turn to our children and our children's children through unlimited generations We do so merely by the influence of a single living cell The male cell, with all its infinite variety of mechanisms and possibilities, weighs something of the order of a one hundred millionth of a milligram Picture the whole paternal inheritance of all the people in the United States of America derived from a single milligram of material the inborn characteristics of the entire human race present on the earth to day drawn from chromosomes weighing less than a single drop of water The astronomers arouse our imagination and envy by their tales of the almost infinitely great think of all future human history, in its endless variety, depending on material weighing less than a pin, *then* we can realise that the problems of biology are not altogether easy

Vitalism and Mechanism

Much labour and much skill have been devoted for many years to the study of such highly differentiated tissues as muscles and nerves We do not pretend to explain the growth, the apparently purposeful development of these in the body Our highest aim for the moment is to understand their working Success, though meagre, has been sufficient to give us confidence that there is nothing to stop us on the road of our desire To the degree that physics and chemistry are reasonable and intelligible, so also the phenomena of life are reasonable and intelligible It is quite sure that no sentinel stands across the path to forbid our

further advance We hear much discussion of the relative philosophical merits of mechanism and vitalism both contain elements of truth, but the whole truth is neither in the one nor in the other

There is no more reason for expecting to explain life in terms of physics than physics in terms of life The powers of the human intellect alone are the limit to our understanding of either When a physical event occurs in a living cell or creature it has a physical cause, which, assuming we are skilled and clever enough, we can discover If, however, as Jeans says, all physics is ultimately mathematics and the order behind the universe is mathematical, then, mathematics being a function of one corner of the human mind, physics is ultimately physiology! Philosophically we can have it which way we like practically, in biology, we must make good and significant experiments and observations

Competition and Co operation

If we survey the totality of living things, we see two main forces at work that of competition or the survival of the fittest, that, on the other hand, of co operation in the service of the community The higher animals are communities of cells—and the cells must work together or the community will perish Man is a gregarious creature, he lived at first as a member of a family, then as a member of a tribe, more recently as a member of a nation Some day, it is certain, he will live as a member of mankind The evolution of mankind as a living organism has been extraordinarily rapid in recent years, that of man the individual is bound to be, at the present stage and hereafter, very slow Already we see, in such organisations as the League of Nations, the idea at work of mankind as a single organism, trusting not chiefly to the survival of the fittest, but to the principle of co operation The conception of mankind as a living biological unit is one of great significance for the future of the race By eugenics, so far as it is practicable—and with further knowledge it may become not only practicable but easy—we shall ensure that survival of the fittest shall continue to keep the race from degeneration, without the bloodshed and cruelty of its natural incidence By co operation we shall make certain that the malignant growths of national hatreds do not wreck an otherwise healthy organism

The Claims of Biology

I make strong claims for biology—but do not think I am advertising my own wares Indeed, if I can analyse my motives properly, I am protesting against my own ignorance of, my own lack of education in, the most interesting things in the world Had I spent a little less time at Latin and Greek, had the theory of equations and the convergence of infinite series loomed a little less large on my horizon, I might have had time, if someone would have taught me, to learn about living things at an age when they could be remembered Knowing just enough, however, to realise the wonder, the beauty, the complexity of life in its scientific sense, and the degree to which workers with every variety of mind can contribute to the living organism of biological knowledge, I have set out to urge that the claims of biology must be treated very seriously

There are not many departments of knowledge in which its contribution can be neglected, there are not many aspects of life which can remain indifferent to its teaching Nearly half a century ago died Francis Maitland Balfour, brother of Mrs Sidgwick, a man whose early promise—could it have been fulfilled—would have placed him among the greatest of Cambridge biologists Another brother, Arthur James Balfour, died recently all his life a friend, and far more than a friend, of science, even in his last years he rendered, by his counsel, very important service to medical research and to applied psychology Henry Sidgwick him self, were he alive to day, would have been one of the first to see the significance of biology, in its wider aspects, in matters of human conduct The days fortunately are gone when children had to be informed that babies are sent down ready made from heaven The stage has been passed where full grown men and women can be told that the ideas of absolute good or evil are derived from the same mysterious source Henry Sidgwick's ethics was in keeping with the point of view of to day, that the idea of good is intimately associated with the highest welfare of the race with the notion that the health, the happiness, the wisdom, the beauty of mankind as a sentient living organism must be the final arbiter in deciding what is good and right

Printed in Great Britain by R & R. Clark, Limited, *Edinburgh.*

be the radius of a configuration, arbitrarily assigned beforehand. Let us endeavour to construct a gaseous configuration with this radius. If such a configuration be capable of being constructed, let us in imagination take a journey inwards to the centre, starting from the boundary. Let M be the total mass, $M(r)$ the 'surviving' mass left inside the sphere of radius r when we have reached the distance r from the centre. Then $M - M(r)$ is the mass already traversed. Consider now the influence of light-pressure. If L is large, light-pressure will be large and will balance an appreciable fraction of gravity, and accordingly the density gradient will be small. But if L is small, light pressure will be small, and the density-gradient will be large. Thus, when L is large, we shall have traversed a smaller mass $M - M(r)$ in the shell between r_1 and r than when L is small. Consequently, when L is large, $M(r)$ will be larger than when L is small. In other words, as we journey inwards, when L is small we 'consume our mass' faster than when L is large. If L is sufficiently small, we may have consumed our whole mass M before we arrive at the centre; in that case the only configuration of radius r_1 and mass M is a hollow shell internally supported by a rigid spherical surface. If L is sufficiently large, we shall, however, tend to have an appreciable mass $M(r)$ surviving unconsumed however near we approach the centre, and this surviving mass $M(r)$ can only be packed inside r at the cost of high density with violation of the gas laws. Thus these configurations for large L must be centrally condensed. For small L, on the other hand, no configurations of radius r_1 and mass M, unsupported, can exist, and the actual configurations must be 'collapsed' ones. 'Collapsed' configurations prove to be much more nearly homogeneous than 'centrally condensed' ones.

Scientific Centenaries in 1931

WITH the forthcoming celebrations in London in September, first of the centenary of the discovery by Faraday of electromagnetic induction and then of the centenary of the British Association, the year 1931 promises to be one of outstanding interest to men of science, especially as these events will be preceded by the Second International Congress of the History of Science and Technology, also to be held in London. At Cambridge, too, a committee of distinguished men has been appointed in connexion with the centenary celebrations of the birth of Maxwell (1831–1879). Among other famous physicists who were born the same year as Maxwell were P. G. Tait (1831–1901), D. E. Hughes (1831–1900), Sir Francis Bolton (1831–1887), a founder of the Institution of Electrical Engineers, S. H. Burbury (1831–1911), and Johannes Bosscha (1831–1911), once the acknowledged leader of Dutch physicists, while a hundred years ago died J. T. Seebeck (1770–1831), the discoverer of thermo-electricity, and Henry Foster (1796–1831), the Copley Medallist of the Royal Society in 1827. Two hundred years ago, on Oct. 10, 1731, Cavendish was born at Nice.

Among the anniversaries of 1931 of great interest to mathematicians is that of the tercentenary of the death of Henry Briggs (1561–1631), the first Gresham professor of geometry, and from 1620 Savilian professor at Oxford, an appointment in which he succeeded Savile himself. The first improver of logarithms after Napier, Briggs wrote two great works, his "Arithmetica Logarithmica" and "Trigonometria Britannica". At his death Briggs was buried beside Savile in the chapel of Merton College. Another well known name is that of Brook Taylor (1685–1731), "one of the most able British mathematicians after Newton", and secretary to the Royal Society. Baron Maseres (1731–1824), the mathematician and judge, was born the year Taylor died. Maseres, Taylor, Briggs, Burbury, Cavendish, and Tait, like Maxwell, were all graduates of Cambridge; while last century, few Cambridge mathematicians had a higher reputation than E. J. Routh (1831–1907), who shared the Smith prize with Maxwell. The year 1831 also saw the death of the remarkable French woman mathematician, Sophie Germain (1776–1831).

Of the names of astronomers recalled by the passing of a century, mention may be made of Jean Louis Pons (1761–1831), the discoverer of 37 comets; of the Rev. F. Fallows (1789–1831), the first Royal Astronomer at the Cape of Good Hope, where he died; of Edward Stone (1831–1897), who was the predecessor of Gill at the Cape; and Bredichin (1831–1904), the successor of Otto Struve at Pulkova Observatory. A very notable achievement in astronomy is recalled by the tercentenary of the observation by the philosopher Gassendi, on Nov. 7, 1631, of the transit of Mercury across the sun's disc. The occurrence had been predicted by Kepler, but Gassendi alone among his contemporaries appears to have made adequate arrangements for observing the transit, and happily his foresight and ingenuity were amply rewarded by his success.

Other distinguished men of science born a hundred years ago include the American agricultural chemist, Samuel William Johnson, whose two books, "How Crops Grow", 1868, and "How Crops Feed", 1870, were translated into French, German, Russian, Italian, and Japanese; the German chemist, Hans Heinrich Landolt (1831–1910), who was spoken of in the *Journal of the Chemical Society* as "the patriarch of physical chemistry", and the British chemists, Matthiessen (1831–1870), Northcote (1831–1869), Bloxam (1831–1887), and Atkinson (1831–1900), all of whom enriched chemical literature. The year 1831 also saw the birth of the great Austrian geologist, Eduard Suess (1831–1914), Copley Medallist of the Royal Society in 1903, whose name is now to be seen on a tablet affixed to 4 Duncan Terrace, Islington, where he was born; of Carl Albert Oppel (1831–1865), the eminent German palæontologist; of Othniel Charles Marsh (1831–1899), long in charge of the division of vertebrate palæonto-

logy in the United States Geological Survey, and the discoverer in 1871 of the first pterodactyl remains, and of Eugène Renevier (1831–1906), the distinguished Swiss geologist Swiss science is also represented by François Huber (1750–1831), the naturalist, who, though smitten with blindness, wrote a notable work on the habits of bees, British surgery is represented by John Abernethy (1764–1831), of St Bartholomew's Hospital, one of the foremost medical teachers of his time, the birth of British industrial chemistry by Archibald Cochrane, ninth Earl of Dundonald (1749–1831), who wrote an account of coal tar and established works for the manufacture of soda from common salt, but reduced himself to penury The bicentenary of the birth of Erasmus Darwin (1731–1802) will not only recall an interesting figure of the eighteenth century, but also will serve to remind us that on Dec 27, 1831, his famous grandson, Charles Darwin, left England in H M S *Beagle*

In the realm of engineering and invention many interesting centenaries will fall due Sir Hugh Myddleton, who gave London its first waterworks, died in 1631, Patrick Miller, who, with the aid of Symington, experimented with steam boats in 1788, was born in 1731, while 1831 saw the deaths of Symington himself, of Blenkinsop, a pioneer of the locomotive, of Sir Samuel Bentham, and of Henry Maudslay, probably the finest mechanician of his day The same year saw the birth of Sir Andrew Noble, the great artillerist, of Ludwig Nobel, 'the Baku oil king', of Pullman, maker of the first sleeping-car, and of James Starley, who "by his improvements rendered bicycles and tricycles machines capable of general use", and by his energy raised Coventry to the position of a centre of industry

Obituary

DR ELLWOOD HENDRICK

A *FRIEND* cannot be defined He is never made he comes, when and how who shall say? Only where the wind listeth He cannot be a woman subtle, homosexual harmonies tie the relationship He is the greatest and rarest of discoveries the inestimable loss The intensity of friendship may vary greatly waiting as it does upon opportunity for its upgrowth, ripening with time, its character is of instant determination at least, you know at once who are the people you will like

Ellwood Hendrick, almost by his name, made instant appeal to me ten years or so ago when we met at one of our summer chemical gatherings To write the common, catalogued, laudatory notice of such a man is impossible, the more as he has no base professional claim When with him I had the feeling that "Rip van Winkle" was at hand, having Jefferson's inspired presentation of the delinquent in mind– a vision unfortunately impossible to the modern generation Hendrick was a bit of a Rip and both in build and manner of Dutch complexion, with sufficient *Diable au corps*, I believe of Irish origin, to make him artist and humorist as well—no mere testubical chemist Giving avuncular advice on the study of chemistry, he could slyly write—

> You'd better join the Church before
> This course is well begun,
> Because you'll need to exercise
> The art of faith, my son
>
> I used to think theology
> Was rather rough on doubt
> But chemistry with ions beats
> Theology all out

Long an admirer of Lafcadio Hearn—the strangest of hybrids, Greek-Irish by descent—in reading his "Life and Letters", by Elizabeth Bisland (1906), I had wondered what manner of man the Ellwood Hendrick could be to whom Hearn had addressed such wonderful outpourings, even calling him 'Dear, Devilishly Delightful, Old Fellow' (in 1891) Hearn wrote his friend's epitaph in using these words This is what I at once found him to be We exchanged letters freely and it took me but a short time to fathom the secret of Hearn's love of the man The full story of this friendship was given by Hendrick, in an essay he contributed to the *Bulletin of the New York Public Library* last year, he had presented the precious originals of the Bisland letters to the Library in 1919

Hendrick tells how he first met Lafcadio Hearn, in 1888, in New York, at a select gathering of literary people, including Elizabeth Bisland—the most beautiful woman he ever saw Hearn was then on his return from two years in the French West Indies, this was a year before he went to Japan Quickly seeing how utterly miserable Hearn was in the presence of strangers, owing to his intense shyness, accentuated by his partial blindness, Hendrick soon took him away—as an old Heidelberg Corps student should, naturally to 'a none too respectable beer cellar', the only possible place of resort in the circumstances The beer fulfilled its divine appointed purpose They talked of many things In the end Hendrick resolved that here was his opportunity

> " that if this man would only let me, I would cultivate his friendship and be with him as much as I might, for it seemed as though, through him, a light was dawning on my horizon
>
> "Perhaps I had better explain a little about myself I had studied chemistry abroad and had planned to organise a great synthetic organic chemical industry in the United States It had started and proceeded for three years until we finally produced excellent materials But our sales organisation was defective, tariff changes and a bad year ensued, there arose disagreement among the proprietors, the bonds foreclosed and that was an end to it all for me I was young and foolish and resolved to have nothing more to do with chemistry which had been, I felt, a false mistress to me The dreams of my boyhood and

young manhood were shattered, I believed my future to have been destroyed, that nothing but commonplace things would be available to me and that the whole business of living was hardly worth while It was easy enough to make a living by sticking to my job but even if it did lead to a better post and more pay it lacked the distinction on which I had set my heart—and been disappointed In short, my ambition was hardly to be recognised

"I did not tell these things to Lafcadio as I have told them here but he sensed the situation And just as I resolved that night to cling to this man in the hope of enlightment, I believe he resolved to fan the almost extinct spark of ambition in his new companion, who was ten years his junior, until it might burn again and warm his disappointed soul"

Ellwood Hendrick was born at Albany, N Y, on Dec 19, 1861, he died in his New York home on Oct 29, 1930 Educated for the most part abroad, at twenty he became manager of the Albany Aniline Dye Works—it is not surprising that he was unsuccessful He then spent over thirty years in insurance work He returned to chemical work, in 1917, with the Arthur D Little Co, Cambridge, Mass In 1924, he was appointed curator of the Chandler Museum in Columbia University Of late, he exercised a great influence upon the social development of Columbia students, seeking to make them men of the world All sorts of willing helpers came to his aid—distinguished actresses and others He had a very pretty pen, as all know who have his delightful volume of "Percolator Papers" (Harper Bros, 1919), a model in its way—named after the organ of the New York Chemists' Club He could write on subjects so far apart as Saul of Tarsus and C_2H_5OH—even ascribe to the latter the greater influence for good in the world

Hendrick was a perfect letter writer Early in March of last year, he wrote me a rapturous account of "Green Pastures", the work of his friend Marc Connelly "I'm so full of it, I want to write about it to some sympathetic soul" To him it was a wonderful picture of the way in which the 'darkies' took the Bible and adjusted it to their own minds (This may not be without repercussion upon ourselves, if we consider what is the effect upon students of textbook tarradiddles and modern pseudo scientific mysticism) "It is all real from a simple and childish point of view that everybody had once I urge you to see it It is free from all the offensiveness of apologetics" His charm, in fact, lay in his being himself a primitive In "Green Pastures", Hendrick was in the element native to his spirit HENRY E ARMSTRONG

WE regret to announce the following deaths

Mr T F Bourdillon, formerly conservator of forests, Travancore, on Dec 19, aged eighty one years

Dr Geo F Freeman, director of the Federal Experiment Station at Mayaguez, Porto Rico, since April last, an authority on cotton breeding, on Sept 18, aged fifty three years

The Right Hon Lord Melchett, P C, F R S, chairman of Imperial Chemical Industries, Ltd, on Dec 27, aged sixty two years

Prof John Munro, emeritus professor of mechanical engineering at the University of Bristol, on Dec 19, aged eighty one years

Prof Pierre Termier, Inspector General of Mines and Director of the Service de la Carte Géologique, who was elected in 1909 a member of the Section of Mineralogy of the Paris Academy of Sciences, aged seventy one years

News and Views

WE have on more than one occasion had suggested to us that articles on investigations being carried on at various research centres would be of interest to scientific workers elsewhere The selection of such centres is, however, a little difficult, and the result might be regarded as invidious, unless it referred to the activities of a particular investigator and the group of workers around him After all, scientific research is peculiarly individual whether carried out alone or with the help of others It seemed to us, therefore, that an approach to investigators themselves, inviting them to state the main subjects to which they are now devoting attention or problems which they would like to see solved, might lead to some interesting and suggestive notes Inquiries, with this intention, have been sent to a number of people engaged in research, and in another column we associate replies received with the birthdays of those who have sent them It is proposed throughout the year to publish similar notes under the title of "Birthdays and Research Centres", and we believe that the information thus brought together will prove of wide interest

IN the issue of NATURE for Dec 27, under "News and Views", reference is made to "the birthday anniversaries of three veteran workers in science and educational progress" In the case of Dr William Garnett, who celebrated his eightieth birthday on Dec 30, mention should be made of his work in Newcastle and the counties of Northumberland and Durham during the ten years he resided in Newcastle upon Tyne When in 1884 he was appointed principal and professor of mathematics in the Durham College of Science in Newcastle, he found the College still in occupation of temporary premises ill adapted for its work Circumstances combined to crown Dr Garnett's insistent advocacy for the erection of special buildings, a site was acquired, and building operations begun with the north east wing, which was opened in 1888, to be followed six years later by the completion of the south east and south west wings In 1894 Dr Garnett resigned the principalship to take up the organisation of technical education for the London County Council Since that time the work in Newcastle has progressed, not only is the main building completed, but also many others have been erected on the site, in connexion with what is now known as Armstrong College Further, it was mainly on Dr Garnett's initiative that the University of Durham sought and obtained a supplementary charter, which provided for the admission of women to degrees in all Faculties save that of theology, a restriction removed later when the University was reconstituted Finally, Dr Gar-

nett took an active and prominent part in promoting and organising schemes for technical education, not alone in Newcastle, but also in the counties of Northumberland and Durham

JAN 5 is the bicentenary of the death of Étienne François Geoffroy, the French chemist and physician, who was a fellow of the Royal Society and a member of the Paris Academy of Sciences Born in Paris, Feb 13, 1672, the son of a well to do pharmacist, Geoffroy studied at Paris and Montpellier, visited various parts of France, and came to England as physician to the French Ambassador In 1707 he was made professor of chemistry at the Jardin des Plantes and later on became Dean of the Faculty of Medicine at the Collège de France He did much by his personal influence to mitigate the severity of the strife then raging between Parisian physicians and surgeons, and he was the author of a "Traité de la matière médicale" which was published after his death "Geoffroy", says Senier, "was the first to construct Tables of Affinity, in which the substances are arranged in columns, each having successively less attraction for the one mentioned first This was undoubtedly a very great advance, and led directly to the important work of Bergmann" Geoffroy's younger brother, Claude Joseph (1685–1752), also a member of the Paris Academy of Sciences, wrote some sixty memoirs on natural history and chemistry, while his son, Étienne Louis (1725–1810), a correspondent of the Institut, was the author of the "Histoire des insectes des environs de Paris" and other works

EARLY last year we directed attention to the pamphlets issued by the Safety in Mines Research Board headed "What Every Mining Man should Know" The third of these pamphlets has just been issued and has for its title "How Some Firedamp Explosions are Prevented" The pamphlet explains in simple language the various methods used to safeguard against gas explosions (to use the phrase of the pamphlet itself) It would perhaps have been wiser to have spoken everywhere not of a safeguard against gas explosions but of minimising the danger of gas explosions, because it cannot be too often repeated that no invention yet produced is an absolute safeguard against explosions, but that the various modern methods described in this pamphlet do make explosions of firedamp far less likely to occur It is needless to say that the pamphlet is well and clearly written, but it may be doubted whether it will really accomplish its desired end First of all, as has already been pointed out, it is doubtful whether any large number of coal miners will even take the trouble to read these pamphlets In the second place, it will be seen from the Annual Report of H M Chief Inspector of Mines for 1929 that in that year there were 68 explosions of firedamp causing accidents, of which no less than 50 were caused by the use of naked lights It is obvious that until the prohibition of naked lights in collieries is carried much further than it is at present, explosions of firedamp are bound to occur Nevertheless, it is obvious that the more widely information such as that contained in the present pamphlet is disseminated among coal miners the greater is the probability that the men themselves will learn to take efficient precautions against such occurrences

THE Report of the Science Museum for 1929, recently published by the Board of Education, contains statistics of the number of visitors, particulars of the progress of the various departments lists of acquisitions and their donors, and the report to the Board of the Advisory Council, of which Sir Hugh Bell has for many years been the chairman That the popularity of the Museum has increased during the last few years, and especially since the opening of the new galleries in Exhibition Road, is well known The efforts made to meet the public taste have indeed been so successful that at times the galleries have been inconveniently crowded Attendance charts included in the Report show, as might be expected, three peaks coinciding with the school holidays at Christmas, Easter, and August, when the Museum is thronged with boys and girls The working models, a feature the Museum owes to the late Mr Isaac Last, have always proved attractive, and though it may be doubted that the working of, say, the Rateau steam turbine, is understood by many who turn it round, there are simpler exhibits which the young can understand With reference to this, the Report says "A most interesting and instructive series of working models, within the range of their intelligence, could be designed and exhibited in a special gallery or galleries, which would serve as an introduction to the exhibits in the main galleries" There is no room at present for such a collection, but a commencement has been made with the construction of the models required

THE question of further accommodation at the Science Museum is referred to several times in the Report, which states that it is not possible to exhibit certain objects or develop some of the collections, owing to the want of space About seventeen years ago, the late Sir Francis Ogilvie read a paper on the Science Museum to the Royal Society of Arts, and this, when published, contained a plan of the new buildings as suggested by the Departmental Committee on the Science Museum and the Geological Museum The plan showed a range of buildings extending from Exhibition Road to Queen's Gate Had the War not intervened, no doubt the whole of this scheme might by now have been well advanced But so far only one of the three sections has been erected When the great advances made during the last quarter of a century in physical science, engineering, and technology are taken into consideration, we are not surprised that the growth of the collections has outstript the growth of the Museum buildings The new Geological Museum is now being constructed, and it is to be hoped means will be found for carrying on with the second section of the Science Museum In its scope, the Science Museum reflects very fully the great industries on which the material progress of Great Britain depends, and at the same time recalls the work of the great pioneers who made

us, at one time, the engineers and manufacturers for the whole world It is of the greatest value for technical men, teachers, and students to be able to study both past and present practice, as they can do at the Science Museum, while the importance of the Museum as an educational institution is proved by the use made of it by the schools of London and elsewhere

HITHERTO European broadcasting has been very successful in avoiding interference between the waves from transmitting stations, but recently there has been serious interference between London Regional, Mühlacker, Graz, and what is apparently a harmonic from the Warsaw station This is due partly to the small space in the broadcasting spectrum allotted to each of the transmitting stations and to the very high powers now being radiated into space by some of them, but it is mainly due to the fact that the European broadcasting conferences have not the power to control and dictate to the transmitting stations Some of the countries, also, do not respond to their recommendations Luckily, happy relations hold between the broadcasting authorities, and so a remedy for the Muhlacker interference—which has sometimes taken away nearly all the pleasure of listening to the London Regional transmission in the south of England—will be devised The power at present emitted from Muhlacker is 70 kilowatts, and as it is proposed to double it in the future, the necessity of preventing interference is urgent Judging from the number of very high power transmitting stations at present being erected in Europe, it would be well for the broadcasting authorities to look ahead and take steps to avoid interference In this respect Europe is not so happily situated as the United States, where there is a central authority appointed by the Government which can dictate to and control the various transmitting stations In the States, also, there is no risk, as in Europe, of disagreement between two nations on political issues

THE section for scientific and optical instruments and photographic apparatus at the British Industries Fair, Olympia, London, Feb 16 27, will occupy some 6000 square feet on the ground floor of the Grand Hall A joint exhibit has again been organised by the British Optical Instrument Manufacturers' Association There will be instruments for all branches of research and industry and for educational purposes, including a particularly fine exhibit of visual aids to teaching It is, perhaps, not generally known that British manufacturers of optical glass supply lenses to America for cinema cameras and projectors, and that one firm is actually exporting the bulk of its spectacle lenses to the United States Every kind of modern optical instrument is obtainable from British manufacturers, and there are some British instruments not made elsewhere which are used all over the world, including Germany There will be a novel display of marine and aerial lighting equipment, including a flashing buoy-light and aerodrome floodlights and models of lighthouses and airway beacons The section for chemicals at the Fair will occupy some 11,000 square feet on the ground floor of the Grand Hall Invitations to the Fair may be obtained by scientific workers, teachers, and others on application to the Department of Overseas Trade, London, which entitle the holder to travel to and from the Fair by rail at the rate for a single journey plus a third

A DEMONSTRATION of the work being carried out in radiology by the Radiological Branch of the Research Department, Woolwich, was given on Dec 18 and 19 The items were demonstrated by members of the staff, and a general summary was delivered afterwards by the director, Mr V E Pullin Among the items demonstrated were the following —Exhibits illustrating the technique in the preparation of radiographs of metallic objects, the designs and construction of experimental X ray transformers, together with their accessory apparatus, an experimental X ray equipment designed to work at 250,000 volts, with either valve or mechanical rectification, and with or without smoothing condensers, oscillograph studies of the current and voltage wave forms in an X-ray circuit, the construction of experimental X ray tubes up to 300,000 volts, apparatus for the radiographic examination of gun tubes and similar heavy forgings demonstrations of X ray crystal analysis of steel by means of line spectra, where precision measurements to an accuracy of one in a thousand were shown, also X ray analysis of explosives and propellants, together with new designs of X ray spectrum apparatus A large number of guests, both from the Services and outside academic and industrial organisations, were present

IN a communication elsewhere in this issue, Dr V F Hess again raises the question of whether part of the cosmic radiation may come from the sun There can be no question that any solar component is very small, and that the accuracy of most of the older measurements would not have sufficed to show its presence Dr Hess considers, however, that this is established by recent work of Hoffmann and Lindholm with a large high pressure apparatus, which has been used at a height of 2456 metres at Muottas Muraigl, in the Engadine These observers found consistently that the ionisation due to the penetrating rays was about one half per cent greater by day than by night, and, moreover, that the absorption coefficient of the difference in ionisation was about the same as that of the whole of the cosmic radiation Dr Hess takes the view that it is legitimate to suppose that the difference represents the contribution of the sun, and that the absorption measurements show that this is at least as hard as the main radiation Corlin's conclusion—based on a statistical analysis—that the sun is not a radiator, is referred to lack of precision in the data employed by him If Dr Hess's views prove to be correct, and the sun, and so presumably all stars, are to be regarded as sources of the rays, it will become desirable to reconsider critically the alternative view that they arise in interstellar space

CONSIDERABLE interest and no little controversy was aroused in America in 1927 by the announcement

that Mr Harold Cook had discovered metates for grinding corn and an arrowhead in association with fossilised mammalian bones of Pleistocene age in the Holloman gravel pit at Frederick, Oklahoma In view of the verdict passed on similar discoveries which have served as a basis for a claim for a high antiquity for man on the American continent, it is not surprising that the announcement was received with considerable reserve, and the conclusion that the Oklahoma gravels afforded evidence of the contemporaneity of man and a Pleistocene fauna in America was questioned by more than one anthropologist of standing The accuracy of the interpretation of the geological evidence by Mr Harold Cook and others is now disputed by Dr O F Evans, of the University of Oklahoma, in a communication to the *Journal of the Washington Academy of Sciences*, vol 20, No 19 Dr Evans, in the light of his wide experience of the geology of the region, maintains that the gravels of the Holloman pit are a redeposit made after a period of post Pleistocene uplift, having been eroded by a stream in the bed of which the pit was situated This stream was diverted shortly after the redeposit was made The artefacts which were found in association with the fossilised bones had been lying on the surface of the gravels when the latter were eroded, and were redeposited with them Dr Evans's citation of similar deposits in the adjacent area supports his view, to which the relatively recent character of the artefacts—in any case, an element of doubt—gives further cogency Once more 'indisputable' evidence for Pleistocene man in America has failed to carry conviction

THE sixteenth meeting of the International Geological Congress will be held in the United States in 1932, with headquarters at Washington A series of excursions, to occupy about ten days late in May, is being arranged to precede the general sessions these will be partly in the north east, to suit the convenience of those arriving at New York, partly in the southern States, starting from Washington, and in addition there will be a transcontinental trip for those landing at San Francisco The Organisation Committee is planning the preparation and publication of a monograph on the petroleum resources of the world, and papers on this subject will be conspicuous in the programme of the general sessions The latter are provisionally fixed for the early part of June Other topics proposed for special consideration include estimates of geological time, problems of batholiths and metalliferous deposits, sedimentation, geomorphology of arid regions, and fossil man Suggestions for other topics are invited, and should be sent to the General Secretary After the general sessions, two alternative transcontinental excursions are proposed, each occupying 32 or 33 days, and two shorter excursions, one to the iron and copper districts of the Lake Superior region (13 days) and the other to Oklahoma and Texas (10 days) If desirable, the latter may be transferred to the group of excursions preceding the general sessions, in order that petroleum geologists may not be excluded from one of the transcontinental trips Excursions to Alaska and the Hawaiian Islands are also under consideration, and will be arranged if a sufficient number of visitors express the intention of taking part All inquiries should be addressed to the General Secretary of the Organising Committee, Sixteenth International Geological Congress, Washington, D C

THE first annual report of the Executive Council of the Imperial Agricultural Bureaux has been published Eight bureaux dealing respectively with soil science, animal nutrition, animal health, animal genetics, animal parasitology, plant genetics (crops and herbage plants being considered separately), and fruit production were set up in 1929 under the directorship of the heads of the research institutes in Great Britain at which they are located The chief officer, however, in almost every case has had training or experience in some part of the Empire overseas The main function of the bureaux is to act as clearing-houses of information in that branch of agricultural science with which they are concerned, and to promote direct contact with research workers overseas Arrangements have been made for the collection of research information from all parts of the world and for summaries to be disseminated to all workers in the Empire Although the first year was necessarily devoted largely to organisation, several of the bureaux have already been able to make a start in the distribution of the information they have collected Research work is not undertaken by the bureaux, but they are able to put workers in different countries encountering similar difficulties into touch with each other, and thus aid co operation As regards finance, all the Empire countries represented on the Executive Council contribute a share to a common fund A sum of £20,000 was originally suggested as the total yearly contribution, and estimates for next year amount to £19,300 Each bureau is being encouraged to develop along its own lines, but although there may be diversity of detail they all have a common object—service to the workers on agricultural science in the Empire The success of the bureaux, however, depends on the measure of support given by the research workers and the use they make of them

AN Association of International Patentees, Incorporated, with headquarters in New York and corresponding secretaries in various parts of the world, has recently been formed Its objects are to care for the interests of patentees and their congeners, to promote improvements in patent law, to help patentees to find financial support, to organise exhibitions and conferences, and to supply information The movement is at present mainly centred in the United States, though it aspires to become international Its vice-presidents include eleven ministers of various nations accredited to the United States, Dr Hugo Eckener, Prof Einstein, and two distinguished representatives of Canada and British Honduras The advisory board is drawn from England and the United States, the committee on scientific and educational research from Canada and the United States, and the advisory committee on patents from foreign diplomatic representatives accredited to the United States National councils are in process of formation in other parts of

the world The success of such a body in exerting international influence and in attaining its objects—particularly the notoriously difficult one of finding financial support for struggling inventors—must depend mainly on the personality and enthusiasm shown by its more active promoters, and the probable extent of its success can scarcely be predicted at this early stage

PLANS for a new building at the Massachusetts Institute of Technology contain unusual provisions for fundamental research and advanced instruction in physics and chemistry Funds for starting the building, which will join two wings of the present buildings on the east side of the main buildings, are available from the gift of £500,000 by Mr George Eastman in 1916 The new four story structure will include a well-equipped shop for the construction and maintenance of instruments, a lecture room, and a joint library and reading room for the use of the staff and students in physics and chemistry The research rooms have been designed to permit of great flexibility The construction specifications call for a structure of unusual rigidity with foundations of heavy reinforced concrete to aid in eliminating vibration An additional separate spectroscopic laboratory will be housed in a building which will occupy a site in the quadrangle formed by the new physics building The two floors of this laboratory will be supported on a foundation entirely separate from that of the outer walls and the roof of the building This foundation is to be more than three feet thick, and composed of alternate layers of sand, felt, transite board, ground cork, and reinforced concrete These elaborate precautions are expected to eliminate shocks and vibration from industrial processes in the neighbourhood and the movement of traffic on adjacent highways Provision will also be made for maintaining extreme constancy of temperature in this laboratory The equipment will include apparatus which has been collected at Leland Stanford University by Prof G R Harrison, who this year joined the staff of the Massachusetts Institute as Director of the Research Laboratory of Experimental Physics Plans for a cryogenic laboratory for fundamental studies in the science of low temperatures are also under consideration The main physics building is being designed by Messrs Carlson, of the architectural firm of Coolidge and Carlson, and the spectroscopic laboratory by the engineering firm of Charles T Main, Inc

ACCORDING to an article in *Paper Making and Paper Selling*, which has been reprinted by the New Northfleet Paper Mills, the process of making vegetable parchment by immersing suitable paper in sulphuric acid was discovered by W E Gaine in England in 1853 After later investigations by the German chemist, A W Hofmann, and the development of machinery, enabling the production of parchment to be carried out as a continuous process, by a Bohemian paper-maker, Robert Fritsch, the manufacture of parchment developed almost exclusively on the Continent, and within a few months of the outbreak of War the parchment required for the packing of food stuffs for the British Army and Navy was practically unobtainable Since the War, under the initiative of Mr William Harrison (chairman of the Inveresk Paper Company), the British Vegetable Parchment Mills, at Northfleet, Kent, have been established, and this account of their activity, issued by the mills, is printed on imitation Japanese vellum made by the mills and accompanied by a range of samples of British parchment which seems to show that the technique of the production of this valuable product upon a commercial scale is now fully mastered

THE October issue of *Isis*, the International Review devoted to the History of Science, contains an article by the editor, Dr G Sarton, on the discovery of the dispersion of light and the nature of colour The first three pages are devoted to an account of pre Newtonian work, including Markus Marci's decomposition of white light by a prism and his proof that the rays so obtained did not change their colour, and Grimaldi's suggestion that the colours were due to different undulations The next thirteen pages are occupied by a facsimile reproduction of Newton's "New Theory about Light and Colours", which was published in the *Philosophical Transactions* of the Royal Society for Feb 19, 1672 Last year the September issue contained Dr Sarton's article on the discovery of the law of conservation of energy, with facsimile reproductions of Mayer's "Bemerkungen uber die Krafte, etc", in the *Annalen der Chemie und Pharmacie* for 1842, Joule's "Calorific Effects of Magneto Electricity and the Mechanical Value of Heat" in the Report of the British Association for 1843, and a page of Carnot's manuscript written between 1824 and 1832 The comments on the controversy as to the relative values of the contributions of Mayer and Joule sum up the position judicially

SOME months ago the Royal Horticultural Society asked for information about portraits of certain eminent horticulturists and botanists to complete a supplementary volume to *Curtis's Botanical Magazine*, which will contain the photographic reproductions of the portraits and biographical notices of those to whom the volumes were dedicated (one hundred in all) All but one of these portraits have now been traced The portrait required is that of the Rev John Clowes (1777–1846) He was born at Broughton Hall, near Manchester, was a member of Trinity College, Cambridge, and a fellow of the Collegiate Church, Manchester (now the Cathedral) He gave up the benefice on succeeding to the family estates in 1833 In his time he was a prominent orchid amateur, and his fine collection of orchids was left by will to the Royal Botanic Gardens, Kew He should not be confused with the famous Swedenborgian of the same name, whose portrait now hangs in Chetham's Hospital, Manchester, and who died in 1831

NAUKA POLSKA (Science and Letters in Poland), published by the Institute for the Promotion of Science and Letters in Poland (J Mianowski Funds, Warsaw, Staszic Palace, 1930), is a periodic publication, the first volume of which appeared in 1918 It is devoted to general information about the progress of

science and the arts in Poland and abroad, although the Polish side is naturally the dominating feature Unfortunately, the whole of it is published in Polish without even short summaries in any other European language, thereby decreasing its value as a means towards international co operation Of the two volumes published last year, Vol 12 contains a complete list of all archives, museums, libraries, and scientific institutions and societies in Poland, with a concise account of each Vol 13 contains some articles of general interest and special articles on the organisation of learning in several European countries There are also included news of scientific activities both in Poland and abroad, reviews of new books, and bibliographies of sociology and the history of science (1928–30)

DR R S TAYLOR, Principal Medical Officer, Somaliland, reports the occurrence of no fewer than eighteen earthquake shocks which were experienced at Zeila (11° 20′ N , 43° 30′ E) between Oct 24 and Oct 28 One shock occurred on Oct 24, two on Oct 25, twelve on Oct 27, and three on Oct 28 No details of times or intensities are given, but the shocks were probably slight and local only , nevertheless, the report is of interest, because Somaliland is not an 'earthquake country', and earthquakes are very rarely experienced there

THE following have been elected officers for the year 1931 of the Canadian Phytopathological Society *President*—W P Fraser, University of Saskatchewan, Saskatoon, Sask , *Vice-President*—D L Bailey, University of Toronto, Toronto, Ont , *Secretary-Treasurer* —T G Major, Tobacco Division, Central Experimental Farm, Ottawa, Ont

APPLICATIONS are invited for the following appointments, on or before the dates mentioned —A physics master at Cowley School, St Helens—The Secretary for Education, Education Office, St Helens (Jan 13) A research assistant in the physical chemistry department of the University of Leeds—The Registrar, The University, Leeds (Jan 14) An assistant lecturer and demonstrator in chemistry in the University College of South Wales and Monmouthshire—The Registrar, University College, Cardiff (Jan 14) A sewage works chemist in the surveyor's department of the Urban District of Dagenham—The Clerk of the Council, Council Offices, Valence House, Chadwell Heath, Essex (Jan 17)

Our Astronomical Column

Astronomy in Virgil —Mr S B Gaythorpe appropriately celebrates the Virgil bi millenary by a paper in the November issue of the *Journal* of the British Astronomical Association on the astronomical allusions in his poems He notes that Anchises places astronomy high among the arts that make a nation glorious "With the rod they will trace the paths of heaven and tell the rising of the stars" ("Aen " VI) There is a well known problem as to who was intended by Virgil for the unnamed companion of Conon "Who marked out with his rod the whole heavens for man " ('Ecl " III) Many astronomers' names have been suggested, but Mr Gaythorpe suggests that the allusion is simply to the unknown man who first divided the heavens into constellations

Most authorities have assumed that Virgil was quoting from some work that was ancient even in his days when he spoke (in "Georgic " I) of the Bull opening the year with his golden horns Mr Gaythorpe notes that there is a sense in which it was true in his own times In mid April Aldebaran could have been seen to set heliacally, with the horns of the Bull plainly visible in the twilight, and Sirius (also mentioned in the poem) farther to the left It is clear that Virgil recognised the practical use of such observations for regulating the times of sowing and other agricultural operations Mrs Evershed, in a companion paper, notes that Dante, in the "Inferno " and "Purgatorio ", makes Virgil give accurate information on many points of astronomy Virgil seems, however, to have made an error about the southern hemisphere, thinking that its inhabitants reversed not only summer and winter but also night and day , "When dayspring comes to us, there Hesperus kindles his lamp " ("Georg " I) In the corresponding passage in Dante, the travellers have emerged at the antipodes of Italy, so the reversal of night and day comes in correctly there.

Spectrum of β Lyræ —A detailed analysis of the spectrum of this extraordinary star was undertaken at intervals by the late Mr F E Baxandall during the last ten years of his life, and the results of his study are now given in the *Annals of the Solar Physics Observatory of Cambridge* (edited by Prof F J M Stratton) Two series of spectrograms taken at Cambridge, together with an earlier series kindly lent by the Allegheny Observatory, form the basis of this investigation, which adds many details to our knowledge of this stellar system, without, however, deciding conclusively its physical nature The absorption spectrum is apparently of dual origin—an oscillating *B*8–type spectrum, and one of type *B*5, which, though not stationary as previously thought, shows only slight radial velocity variations There is also a suggestion of a third source of absorption lines which may be of the nature of a Trojan planet Contrary to earlier hypotheses, the *B*5 star is apparently smaller and more massive than the *B*8 star, but is surrounded by an extensive gaseous envelope which is responsible for the bright lines Several outstanding anomalies still remain unexplained, but the memoir is a valuable contribution to the subject, and forms a fitting memorial to the labours of its originator

Two more Trojan Planets —The Trojan group of minor planets is growing rapidly Odysseus was discovered some months ago, and two more Trojans are announced in *U A I Circ* No 307 These were discovered at Königstuhl on Oct 17, and designated *UA* and *UB* 1930 Using arcs of six weeks, Drs Kahrstedt and Stracke have deduced orbits that indicate periods so close to that of Jupiter as to justify the designation of Trojans The period found for *UA* is about a year longer than that of Jupiter, but it cannot yet be considered as accurately known There are now five Trojans (including Odysseus) the longitude of which exceeds that of Jupiter by about 60°, and four (including *UA* and *UB*) on the other side of Jupiter The eccentricity of *UA* is given as 0 29, so that it is nearly twice as far from the sun at aphelion as at perihelion The magnitudes of both planets are about 14½ The interesting planet 944 Hidalgo, which travels out almost to Saturn's orbit, is now returning sunward, and an ephemeris is given for next July in "Kleine Planeten ", but as the magnitude is only 18½, it will probably not be detected until the following year Its orbit is quite cometary, but its aspect has always been stellar

Research Items.

Healing in Ontong Java.—Measures taken for healing the sick in Ontong Java (Lord Howe's Island) in the Western Pacific are described by Mr. H. Ian Hogbin in *Oceania*, vol. 1, No. 2. Disease, in common with the weather, success in fishing, sorcery, and a hundred other things which affect the daily life of the people, are caused by *Kipua*. Every individual soon after birth receives a *kipua* (spirit), a double or airy body invisible to ordinary eyes. Although a *kipua* is not closely attached to its owner, it is not free until he dies. It then becomes free, and only then can it interfere in the ways mentioned, in the lives of other people. Illness being caused by the *kipua* can only be treated by ceremonies addressed to the *kipua*. An exception is made in the case of boils, contusions, ringworm, malaria, sprains, and swelling of the limbs, which are treated by natural means. The more serious diseases are classified; two classes, convulsions and paralysis, are regarded as incurable; but each of the remaining classes has its own specialist. The remedies are the property of certain joint families and are transmitted from headman to headman. An essential factor in the healing is a *pule* (cowrie) shell to which unbroken white coconut leaf, pandanus leaf, and a piece of the healer's hair are tied. The first essential is to find out which of the *kipua*, usually the spirits of the man's own ancestors, wish him to live and which wish him to die. Two methods are simple and may be carried out by anyone. The question being put to the *kipua*, the answer is given by knots made in strips of coconut leaf or by small pebbles. The more elaborate method requires the service of the specialist, a medium. When the sick man and his relatives have repaired to the house of the medium, the latter is possessed by each of the *kipua* invoked in turn, who states through him its wish. When the name of the *kipua* responsible has been ascertained, a ceremony follows, in the course of which the *kipua* is besought by prayer to give good things instead of evil.

Spread in British Isles of Black-necked Grebe.—The disappearance of the black-necked grebe (*Podiceps nigricollis*) as a British breeding bird was connected with the drainage of the fen area, but its recent re-establishment and spread shows an adaptability which makes it surprising that it should ever have become extinct. In 1904 it was first discovered to be breeding in Wales, in 1915 in a western lough in Ireland, in 1918 at Tring Reservoirs, and a few months ago C. G. Connell recorded the nesting of at least two pairs in a loch in the Forth area of Scotland (*Scottish Naturalist*, p. 105, 1930). Now C. V. Stoney and G. R. Humphreys have found in western Ireland a colony which they estimate to consist of about two hundred and fifty pairs, and that in a lough not more than two or three miles long and half a mile wide (*British Birds*, vol. 24, p. 170). It has been assumed, in regard to the spread of the black-necked grebe, that the colonists in the British Isles were immigrants from the Continent, where the species breeds in countries no farther away than Denmark, Germany, and Livonia. But the presence of the large Irish colony makes it possible that the new breeding places may have been peopled from the west rather than from the east.

Intestinal Protozoa of Wild Monkeys.—Robert Hegner and H. J. Chu (*Amer. Jour. Hyg.*, vol. 12, pp. 62-108, July 1930) report on an examination of forty-four wild Philippine monkeys, *Macacus philippinensis*, twenty-eight males and sixteen females, to determine whether they are parasitised with intestinal protozoa, and to compare these with species that occur in man. Cysts of *Entamœba histolytica* were not abundant and were mostly uninucleate. *E. coli* was found in twenty-two of the monkeys, and *E. gingivalis* in thirty-seven. *Endolimax nana* was present in twenty-two monkeys and *Dientamœba* in two (this is the first record from the monkey). Three species of *Trichomonas* were recorded. *Giardia lamblia* is a fairly common inhabitant of the duodenum and *Chilomastix mesnili* was present in fifteen monkeys. *Balantidium coli* was obtained from eight of the monkeys and showed great variation in size, probably due to racial rather than to specific differences. The authors consider that the evidence afforded by this investigation is "insufficient to separate as distinct species the eleven types of protozoa described from wild Philippine monkeys and the corresponding eleven types that live in man."

Observations on Living Tissues.—Prof. Eliot R. Clark and his colleagues in the Department of Anatomy of the University of Pennsylvania have recently developed a method of studying the living tissues of the rabbit's ear (*Daily Science News Bulletin*, Science Service, Washington, D.C.). A double-walled chamber or window, one wall being of celluloid or glass and the other a very thin sheet of mica, is so arranged on the ear of a rabbit that a thin layer of tissue is enclosed between the two walls of the chamber and can be examined microscopically. As the chamber can remain in place for months, the same area of tissue can be repeatedly observed and the details of the blood circulation studied; and in specially thin tissue, which can be examined with an immersion lens, the growth of cells and of capillaries can be followed day after day. The method will be of value also for the study of transplantations and of the reactions of tissues to different conditions.

Fungi in Butter.—Grimes, Kennelly, and Cummins have carried out an examinaton of butter samples taken with all suitable antiseptic precautions from the interior of a 56 lb. sample which had been kept at low temperature for two weeks, since it was packed at an Irish creamery. The cream is pasteurised, and none of these moulds was found to survive the temperature of pasteurisation. It is concluded that they have probably entered the butter either from the churn or the air (many creameries are near the road side, which increases the risk of contamination from this source). A list of twenty-nine moulds found in the butter is given in the *Scientific Proceedings* of the Royal Dublin Society, vol. 19 (N.S.), October 1930, and the authors note that many of them appear to deviate a little from the standard type of their species, which they think may be due to a process of development of insular strains, peculiar to Ireland.

Climatic Changes during the Pleistocene.—Dr. G. C. Simpson deals very fully with this still tantalising subject in the *Proc. Roy. Soc. Edinburgh*, **50**, pt. 3, No. 21, pp. 262-296, 1930. It is assumed that the glaciation of northern Europe during the Pleistocene was due to a shift of the pole associated with appreciable variations of solar radiation. The shift of the pole brought Europe into sufficiently high latitudes to permit the formation of an ice-sheet, but the variations of climate, such as are shown by the inter-glacial epochs, were due to the oscillations of solar energy. With two complete cycles of solar radiation it becomes possible to account for four advances of the ice. The Günz-Mindel and the Riss-Würm inter-glacial epochs occurred at the maxima of solar

radiation and were therefore warm, they were periods of increased precipitation in all parts of the world, corresponding to the two pluvial epochs which are known to have occurred during the Pleistocene. The Mindel Riss interglacial epoch is correlated with a minimum of solar radiation and it is therefore regarded as having been relatively cold and characterised by low precipitation. The sequence of vegetation types accompanying the climatic changes from maximum to minimum are park land, forest, tundra, grass with sparse trees, and steppe. The deductions are supported by the geological and archæological evidence available, and in particular it is possible to arrange the sequences of human culture, of the geological strata of East Anglia, and of the history of the ice age in the Alps into the inferred scheme of climatic changes.

Steam Tables. The August issue of the *Journal of Research* of the Bureau of Standards, Washington, contains an account of the determination of the thermal properties of saturated water and steam from 0° C. to 270° C. by Messrs. N. S. Osborne, H. F. Stimson, and E. F. Fiock, and a critical review of the measurements of these properties now available by Mr. E. F. Fiock. The determinations were made by electrically heating in a closed vessel a sample of the fluid at one saturation state until it attained a second saturation state, and measuring the electrical energy necessary. The results are expressed in tables of heat content of liquid, latent heat, heat content of vapour, in international joules per gram, of entropy of liquid and entropy of vapour in international joules per gram per degree Centigrade, for each 10° C. from 0° C. to 270° C. The results of the critical review of existing data are embodied in charts of the same quantities, and they show that from 0° C. to 100° C. the published steam tables agree with each other within the limits of tolerance of the International Skeleton Steam Tables of 1929, but that at higher temperatures several of the tables give figures which lie well outside these limits.

Thunderstorms and Penetrating Radiation.—The idea has been entertained that part of the penetrating radiation (or 'cosmic rays') might be due to the action of the large fields known to exist in thunderstorms. Prof. Millikan was, however, unable to obtain any evidence for this, and a new investigation by a different method, described by B. F. J. Schonland in the December number of the *Proceedings of the Royal Society*, confirms Prof. Millikan's result. On the contrary, it has been shown by Dr. Schonland that a *reduction* in the intensity of the radiation takes place when there is an active thunder cloud overhead, the effect being greatest for those clouds for which there was evidence that the upper positive charge was in excess. The quantity of water in the clouds is quite inadequate to account for the screening, which must be attributed to their electrical fields. From Dr. Schonland's discussion of his results, it appears that the upper limit to the energy of most of the quanta or corpuscles which make up the penetrating radiation must be less than 5×10^9 electron volts, a number which is reasonably consistent with the penetrating power of the rays. Dr. Schonland's results do not show definitely the nature of the primary radiation, but indicate that it consists either of ultra gamma quanta or of positively charged particles.

Energy Losses of Electrons in Carbon Monoxide.—Study of the energy losses of electrons in a gas, although yielding far less precise information than can be obtained spectroscopically, affords a valuable check on data obtained by the latter method, particularly in the matter of the probability of certain types of transitions. An investigation of the motion of electrons in carbon monoxide, described by Dr. E. Rudberg in the December number of the *Proceedings of the Royal Society*, shows that the important characteristic losses in this case correspond to 8.19, 11.17, 13.14, and 16.72 volts. The first two of these can be identified fairly closely with transitions of the molecule from the fundamental state, which is simple ($^1\Sigma$), to other singlet states, indicating that such rearrangements of the molecule, under this particular stimulus at least, are more probable than transitions from the fundamental singlet state to the other well known triplet states. The transitions are not, however, those which correspond to the minimum vibrational energy of the higher state, but to rather higher vibrational energy, in general accord with the principle that the change in the separation of the nuclei of the diatomic molecule is small in such cases. The other two losses of energy probably correspond to transitions to a higher (G) state, of which little is known, and to a state of the ionised molecule, respectively. Dr. Rudberg also gives data for the characteristic losses in carbon dioxide, but in this no correlation with spectroscopic data is possible, as the spectrum of this gas is as yet almost unknown.

Proteolytic Enzymes of *Carica Papaya*.—Nag and Banerjee (*Trans. Bose Research Institute*, Nos. 18 and 20, 1930–31) find that two proteolytic enzymes can be separated from unripe papaw fruit by shaking the expressed juice with kaolin and centrifuging. The liquid then contains an 'ereptase' which digests Witte peptone but not fibrin, while from the kaolin sludge can be extracted with salt a 'peptase' acting on fibrin but not on peptone. On the basis of these findings, the authors criticise the view of Grassheim that papain is a single tryptic ferment and agree with Vines that two enzymes are present.

Configuration of the Benzilmonoximes.—Experiments on the solubilities of the α- and β-monoximes of benzil in benzene are recorded in the October number of the *Journal of the Chemical Society* by T. W. J. Taylor and M. S. Marks, and the results are said to support the configurations for these compounds given by Meisenheimer. The argument is based on the assumption that the α-oxime in physical properties should be a hydroxylic substance, whilst in the β-oxime the typical hydroxylic physical properties should disappear, together with the assumption that the solubility of a hydroxylic substance is less than the 'natural' value calculated from the melting-point and latent heat of fusion. The Beckmann transformation, in this case at least, thus involves the groups in the *anti* position to one another.

Intensive Drying.—Some experiments on the vapour pressures of intensively dried benzene, described in the November number of the *Journal of the American Chemical Society* by E. J. Green, show that benzene which has been dried with phosphorus pentoxide in a fused glass apparatus for three years does not exhibit any change in vapour pressure with respect to the normal liquid in the same apparatus. Experiments are described which support the theory that the vapour pressure differences from the normal state may be explained by assuming the presence of minute traces of water vapour in the normal liquid rather than any catalytic effect due to the removal of water from the dried liquid. Calculations from solubility data show that only 0.000229 gm. of water is required to produce a partial pressure of 7 mm. of water in 1 gm. of benzene at 20°, whilst Raoult's law would require 405 times more water.

Geo-electrical Prospecting by A C Bridge Methods *

By A B BROUGHTON EDGE

ELECTRICAL methods of exploring for mineral or for investigating geological structures are numerous, but with few exceptions they fall into two groups, according to the manner in which the ground and the concealed conductive bodies lying within it are excited, and how the resulting electrical field is investigated

(i) *Surface Potential Methods* —In these, direct or alternating current is passed conductively through the ground between earthed electrodes spaced up to a mile or more apart The prospecting operations consist in determining the resulting distribution of potential in the ground and in interpreting the geological significance of any anomalies that are recorded

(ii) *Electromagnetic Methods* —In these, the ground is excited inductively by means of loops of insulated wire suitably disposed on the ground surface and carrying alternating current, usually at a frequency between 200 and 60,000 cycles per second The survey is then carried out with portable search coils, by means of which investigations are made of any anomalies that appear in the magnetic field

The object of the present article is to describe two methods of using a form of A C bridge (ratiometer) for electrical prospecting purposes, one of which comes under the first and the other under the second of the two groups that have been defined above The general principle, which is that of the ordinary A C bridge, was first applied by the author in 1925 to surface potential surveys carried out in Rhodesia The method was afterwards used in Australia by the Imperial Geophysical Experimental Survey, and from it the A C potential ratio method and instruments in the forms described below were developed

FOR DETERMINING SURFACE POTENTIALS

In order to explain the advantages of the A C potential ratio method it is necessary to refer to the well known equipotential line system which, hitherto, has been the only generally known means of investigating A C surface potentials Although the tracing of equipotential lines over the surface has the advantage of simplicity, it also has a serious defect, since it takes no account of the complex phase conditions that arise when alternating current is applied to ground of variable conductivity In such circumstances the resultant field has an *elliptically polarised* structure, in which true equipotential points can only have an instantaneous existence Although the conception of equipotential lines in such an alternating field is theoretically unsound, the out of phase effects met with in practice are not so great as a rule as to preclude the mapping of lines from which a general idea of the conductivity conditions can be obtained It often happens, however, that a survey of this kind becomes a very slow and inexact performance, and sometimes, when in the neighbourhood of important conductive bodies, the phase conditions are such that the method breaks down completely

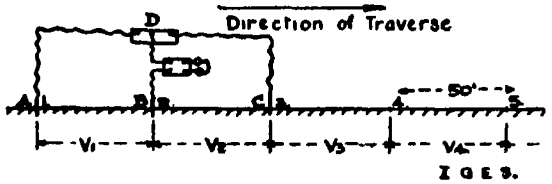

FIG 2 —Field procedure A C potential ratio method

The fact that this system becomes increasingly inaccurate as a buried conductor is approached is a sufficient indication that an additional surface potential method is required, by which the phase anomalies, which themselves are of diagnostic value, may be properly determined The A C potential ratio method described below is intended to fulfil this purpose

The principle of the method is shown in Fig 1, in which A, B, and C are contacts made with the ground and AO and CO are ratio arms in each of which a condenser and a resistance are connected Alternating current, usually at about 500 cycles per second, is passed through the ground between distant earthed electrodes The purpose of the device is to compare the potential drops V_1 and V_2 between the equidistant pairs of contacts AB and BC, and to determine the difference in phase angle between them To accomplish this, the capacity and resistance in each arm are adjusted until an exact balance is indicated by silence in the headphones The potential drops V_1 and V_2 will then be directly proportional to the total impedances † in the arms AO and OC respectively, or in terms of the resistances R_1 and R_2 and the capacitative reactances X_1 and X_2, which are read directly from the instrument

$$V_2 = \frac{R_2 \sin \tan^{-1} (R_1/X_1)}{R_1 \sin \tan^{-1} (R_2/X_2)} V_1$$

and $$\theta_2 - \theta_1 = \tan^{-1} R_2/X_2 - \tan^{-1} R_1/X_1,$$

where $\theta_2 - \theta_1$ is the difference in phase angle between V_2 and V_1, being of positive value when V_2 is leading V_1

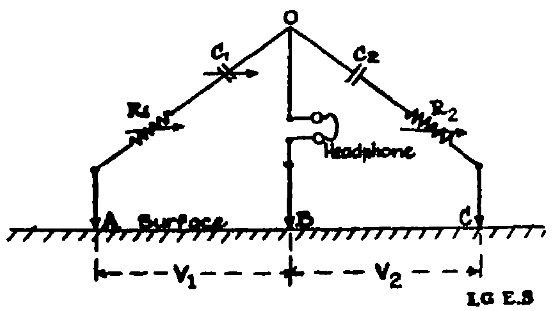

FIG 1 —Principle of A C potential ratio method

In Fig 1 the capacity and resistance in each arm are connected in series, but other combinations may be used As a result of a recent suggestion by D C Gall, an instrument is now being made in which a variable resistance alone is included in one arm of the bridge, the other arm containing a fixed resistance and variable condenser connected in parallel By this arrangement a larger phase angle range is available and the advantage of direct reading is obtained In the previous designs a somewhat tedious series of computations is necessary in order to obtain the potential ratios and differences in phase angle

As a rule, the field observations are made along

* Detailed descriptions of these methods and the apparatus employed will be included in the forthcoming publication of the Imperial Geophysical Experimental Survey, entitled "Principles and Practice of Geophysical Prospecting" This preliminary account is published with the approval of the Geophysical Executive Committee

† These should be of the order of 100,000 ohms Otherwise the accuracy of the determination may be seriously affected by the unknown contact resistances at A and C which enter into the measurement

straight lines, in the manner shown in Fig 2, the station interval depending upon the nature of the problem under investigation but usually being about 50 feet

The apparatus consists of three steel rods A, B, and

FIG 3—Ratiometer in use with amplifier on the operator's back

C, driven into the ground and connected to the ratiometer D, which is carried by the operator together with the headphones and amplifier as shown in Fig 3 Observations are made along the length of the traverse, the operator and his assistants moving forwards one station at a time, so that ratios are obtained for every successive pair of stations In the case shown in Fig 2, V_1 would be taken as an arbitrary unit and V_2, V_3, , etc, would then be referred to it by successive multiplication of the individual ratios $V_2/V_1, V_3/V_2$, , etc * A potential anomaly curve may then be constructed by plotting these multiplied ratios above the mid points of the station intervals to which they refer The differences in phase angle are summed consecutively, positive or negative as the case may be, and are plotted in a similar manner as a phase variation curve

It will have been observed that in order to obtain a balance with the bridge it is essential that the earth at contact B should be intermediate in potential with respect to the contacts at A and C It may happen, therefore, that even on a straight line traverse, points will be met with beyond which it is impossible to proceed in the ordinary way This difficulty may be overcome by side-stepping and including one or more stations off the line of the traverse, but with a bridge of a somewhat different design, now under construction, these deviations should no longer be necessary

In many cases it is sufficient to carry out a series of selected straight line traverses over the ground to be examined and to prepare potential and phase variation curves in the manner indicated above If a more systematic survey is required, observations must be made along a network of lines so that potential and phase values may be assigned to each station within the area These values are determined by vectorial addition and, after adjustment of closing errors, equipotential and iso phase lines may be interpolated

Field experience in Australia has shown that variations in ground conductivity are recorded very faithfully by this method In favourable circumstances the potential curves exhibit a well defined peak over each wall of a buried conductor, and with further research it is thought that the corresponding phase anomalies will be found to have a still greater diagnostic value In some districts in which marked variations occur in the surface conductivity, the method may be at a disadvantage unless the features to be investigated are of an outstanding character It is of particular service, however, as an auxiliary to the equipotential line method which, although of admitted value for reconnaissance purposes, is too crude for detailed investigations

For Comparison of Electromagnetic Fields

This application of the ratio arm bridge relates to the simultaneous comparison of magnetic fields at different points in the neighbourhood of conductive bodies, and the case of the vertical components at two points A and B is illustrated in Fig 4 The two identical coils C_1 and C_2, each having an area of several square feet, are supported in a horizontal position immediately above the points A and B and are connected together so that the e m f's induced in them will *assist one another* The ratiometer is then inserted into the circuit in the manner shown and is operated in precisely the same way as in the surface potential application of the instrument By this means the field intensities may be compared and the differences in phase angle determined Similar observations may be made for other positions of the coils and, in fact, the apparatus may be used in various ways for investigating the character of the ellipse at any point, provided that the differences in phase angle do not lie outside the range of the bridge It has been pointed out by D C Gall that in such cases a mutual inductance bridge would be more satisfactory and such an instrument is now under construction

As a rule, the field procedure and plotting of intensity and phase variation curves will be carried out

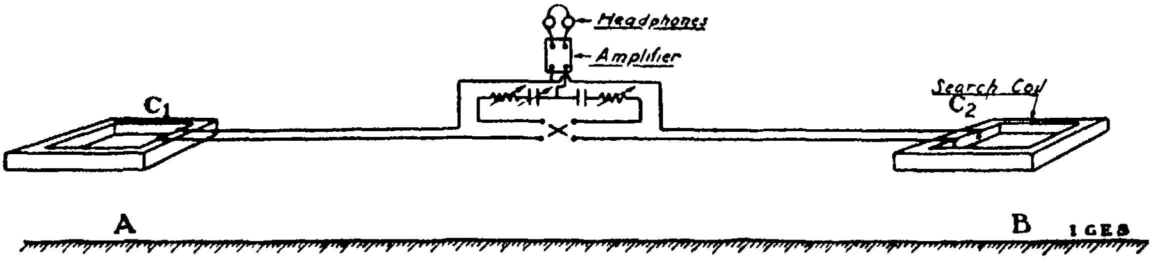

FIG 4—Comparison of magnetic fields with the ratiometer

* This multiplication is of complex numbers, that is, V_2/V_1 and V_3/V_2 are multiplied to obtain the magnitude of the product, and their phase angles are added to obtain the phase of the product.

in the manner already described for the surface potential method, but lines of equal magnetic intensity and iso phase lines may also be drawn

The method described above resembles the two-coil balancing system due to Sundberg and Lundberg, in which two similar coils are joined *in opposition*, with an amplifier and telephone included in the circuit In this case the relative strengths of the vertical fields are given by the secant of the angle through which one of the coils must be tilted out of the horizontal in order to produce a minimum of sound in the telephone It has been pointed out by Eve and Keys,* that this procedure is not always satisfactory owing to phase difference in the currents induced in the two coils, and the fact that the tilting of one of the coils will usually introduce a horizontal component into the determination These writers actually suggest a capacitance bridge in this connexion, but fear that such an instrument would prove too cumbersome for use under ordinary field conditions

Nomenclature at the Eleventh International Zoological Congress

THE account of the International Congress of Zoologists at Padua, published in NATURE for Sept 27, 1930 (pages 489 490), contained only the briefest reference to the discussions and conclusions on nomenclature The following account, which is strictly unofficial, may be of interest

The International Commission on Zoological Nomenclature consists of eighteen members, distributed so far as is practically convenient throughout the world Most of its work is conducted by correspondence, the intermediary being the secretary The present secretary is in Washington and is permitted by the U S Government to avail himself of official facilities

The commissioners meet in person at the International Congresses of Zoologists, which hitherto have been triennial, except for an interval from 1913 (Monaco) to 1927 (Budapest), but which by a resolution at Padua are henceforward to be quinquennial Hitherto each commissioner has been appointed for the triennial period , whether this will now be changed for a quinquennial period remains to be seen

Certain changes in the mode of appointment were accepted by the Padua Congress To replace the retiring commissioners, who are eligible for reappointment, the Commission, after considering the balance of subjects and of geographical regions, submits names to the Section of Nomenclature The Section can propose other names The nominees of both Commission and Section are referred to the Permanent Committee of the Congress, which makes the selection and reports it to the plenum of the Congress for confirmation

The commissioners assemble a week before the Congress opens, and work all day and every day at final discussion and voting on the questions raised during the interval These may be either opinions on points of nomenclature or proposals for alteration of the rules

Opinions are settled by a majority vote of the Commission, and this is generally obtained by correspondence

Proposed changes in the rules must also have received a preliminary majority vote of the whole Commission, that is, ten out of eighteen, and must then receive the unanimous vote of those present at the Congress, nine being a quorum It follows that, on one hand, eight commissioners may have opposed a proposal in writing, but that nine present in person may carry it , and on the other hand, that seventeen may have been in favour, but that one if present may block it These are extreme suppositions, but in actual practice the situation is no better, because of the difficulty of bringing all the members together, or even of obtaining a quorum of the actual commissioners To overcome this difficulty it has been the custom to appoint substitutes (alternates) for the absent commissioners from among zoologists attending the Congress Thus many of those who actually vote may have an imperfect understanding of the questions at issue. At Padua the preliminary work was done by the chairman (K Jordan), the secretary (C W Stiles), and three other commissioners , two more commissioners arrived later, but a quorum was not formed until alternates were appointed Of these there were no less than eleven, and among them Lt Col J Stephenson, Mr G C Robson, and Mr H W Parker acted for commissioners in various parts of the British Empire

On this occasion a further difficulty was due to the fact that before the meeting none of the proposals for change in the rules had received enough votes either to kill it or to bring it up for discussion Until the Congress assembled it was impossible to get the necessary votes, and then, even if they were obtained, it was too late for adequate and properly informed discussion

This state of affairs is manifestly undesirable, and for many years considerable dissatisfaction with these arrangements has been expressed, notably with the demand for a unanimous vote by those present There were two alternative amendments to this by law before the Commission, but unfortunately neither received enough preliminary votes to enable it to be discussed

The same was the fate of other important proposals Among them were alternative motions which would have had the effect of raising type designation by elimination from the status of a recommendation to the status of a rule This is a difficult question, and it is a pity that it could not be thrashed out

A proposal to revert to the XII Edition of Linnæus' Systema Naturæ" as the starting point of zoological nomenclature was definitely rejected, and the date of the X Edition was fixed precisely as Jan 1, 1758, in Article 26 of the rules

The definition of publication for purposes of systematic zoology was discussed at length, and the conclusions will eventually be submitted in the form of an opinion

The report of the British National Committee on Entomological Nomenclature was presented by Dr K Jordan, and its proposed emendations to the rules were considered A few, of merely editorial nature, were provisionally adopted and others deferred for further consideration

Proposals that superfamily names based on generic names should all end in *-oidea*, that new ordinal names should end in *ida*, and subordinal names in *ina* were discussed and held for further consideration

Proposals to apply the law of priority to family and subfamily names, under certain conditions necessitated by other provisions of the Code, were also inevitably held over The general opinion of the Commission seemed to be against further legislation for groups higher than genera

As regards homonyms, it was agreed that, *ceteris*

paribus, the name of a genus should take precedence over that of a subgenus, the name of a species over that of a subspecies

Article 19 of the rules says that "the original orthography of a name is to be preserved unless an error of transcription, a *lapsus calami*, or a typographical error is evident" It was agreed that the word "transcription" included, or rather was intended to mean, "transliteration" This article has sometimes important results in connexion with homonyms Concerning such trivialities as whether one should write *brownii* or *browni*, the Commission showed a wise impatience It also agreed that when a name, or part of a name in combination, had been spelled in diverse ways by different authors or even by the same author, it was not incumbent on a subsequent author, when making casual references, to follow this diversity of spelling It was enough that he should do so in professed synonymic lists

During the interval between the tenth and eleventh Congresses the Commission had formulated twenty six opinions (Nos 98 123), and these were adopted by the Congress These opinions have been or are being published by the Smithsonian Institution

The Commission would welcome the co operation of special committees for groups of animals Such co-operation already exists for entomology and proves of great advantage

The Commission believes that much confusion would be avoided if students of zoology had the opportunity—if not the obligation—to attend lectures on the rules of nomenclature

I have kept to the last the most controversial of the subjects that came up at Padua This is the interpretation of Article 25b of the Code It is there laid down that "The valid name of a genus or species can be only that name under which it was first designated on the condition (b) That the author has applied the principles of binary nomenclature" Article 26 says "The tenth Edition of Linné's 'Systema Naturæ', 1758, is the work which inaugurated the consistent general application of the binary nomenclature in zoology"

The question in dispute is the meaning of the phrase "binary nomenclature" One interpretation is that it means that form of zoological nomenclature which most zoologists associate with Linnæus and notably with the tenth edition of his "Systema", namely, one name for the genus, with which is associated another, so-called trivial name, to make up the *nomen specificum* The addition of a third name to distinguish a subspecies, or even of a fourth for a variety, does not affect the principle that the species is designated by a double or binary name The essence of the Linnean reform, as first fully expressed in the Tenth Edition, is the introduction of a *nomen triviale* in place of the former *differentia*, the *nomen triviale* being a pure name, not necessarily with any meaning, whereas the *differentia* was a descriptive diagnostic phrase, however short it might be

The other interpretation of "binary nomenclature" reduces it to mean no more than 'binary classification', in other words, the recognition of the two concepts *genus* and *species*, and their nomenclature, according to the old logical method, *per genus et differentiam*

The introduction of this latter method into systematic biology is ascribed to the botanist Tournefort (1719) The method was at first followed by Linnæus as by many others, but he perceived its nomenclatural cumbrousness (as indeed had Tournefort himself) and got over the difficulty by using the *nomen triviale* in place of the *differentia* This he essayed before 1758, but it was in that year, in the Tenth Edition, that he first applied it consistently to the whole animal kingdom

Taking the rules as they stand, any unsophisticated zoologist would, I think, adopt the former interpretation In the successive reports of the Congress and successive editions of the rules I have been unable to find anything that suggests the contrary, with the exception of four opinions (20, 24, 35, 89) These draw a distinction between the terms 'binary' and 'binominal' (undoubtedly they do not mean the same thing) and proceed to imply that 'binary' indicates nomenclature *à la Tournefort*, while only 'binominal' indicates nomenclature *à la Linné*

The history of this interpretation of the phrase 'binary nomenclature' has been given by Dr L Stejneger in a most careful paper (*Smithson Miscell Coll*, vol 77, No 1, August 1924), which leaves no doubt that the revisers of the Code in 1901 really did give the phrase what one may call the Tournefort sense, and that their reason for that interpretation was the desire to include the generic names of Brisson, L T Gronovius, Scopoli, and other writers after 1758 who did not follow the nomenclatural system of Linnæus, and to include them without making exceptions to the rules

That this was their intention was, as Dr Stejneger himself admits, far from obvious, and it certainly has never been clear to a large number of zoologists However that may be, there has been an increasing movement to give the phrase the same meaning as the tautological expression "binominal nomenclature" A proposal to that effect was before the Commission at Padua, but failed to receive enough preliminary votes to bring it up for discussion In the Section of Nomenclature, Dr Walther Horn then proposed the following motion "The Congress shall decide that only those publications shall be held to apply the principles of binary nomenclature in which the use of a single word for a generic name and a single word for a species name is consistently carried out" This was passed by a large majority in the Section, and when it came before the plenary session of the Congress, instead of being referred, as one expected, to the Commission, it was put to the meeting without discussion, and again carried by a large majority

It happens, most unfortunately, that those who support what I have called the Tournefort interpretation are for the most part citizens of the United States and include the distinguished and enthusiastic secretary of the Commission, whereas most of those who support the Linnean interpretation come from the rest of the world and in great part from Europe I do not, however, see any reason why this divergence of opinion cannot be accommodated The resolution does not, in my opinion, involve any alteration of the rules, it is a question of interpretation It does involve a redrafting of certain opinions, but it need not involve any change in their effect or in the acceptance of Brisson and the rest

It should be remembered that in 1901 it was not possible to suspend the rules to meet hard cases That practical reform was first achieved at Monaco in 1913 Therefore in 1901 the upholders of Brisson, Scopoli, and Co were obliged either to alter the rules or to interpret them so as to admit those authors They inadvisedly adopted the latter course and failed to make it clear

Their interpretation has been used, as stated above, to admit the uninominal generic names of certain writers after 1758 who did not follow the Linnean method But those writers did occasionally chance to use a specific *differentia* of a single word, and, on this interpretation, there seems nothing to prevent the admission of those appellations That, however, does not seem desired by anyone

Now we can suspend the rules, and we have already

found it necessary to do so in order to eliminate certain authors who, under the Tournefort interpretation, were admissible (opinion 89).

My proposal therefore is that we should, as the Congress has resolved, adopt the Linnean interpretation, which I personally believe to be the natural meaning of the words; that we should formulate a new opinion admitting the generic names of Brisson and the rest by *ad hoc* suspension of Article 25b; and that we should redraft those opinions that are affected (20 and 24). As for opinion 89, I succeeded at the time in getting it so drafted that its effect would not be altered by the change of interpretation now passed by the Congress.

If these proposals are approved by the International Commission, I do not see why we should not continue to work with that harmony and good feeling which have hitherto prevailed at our meetings.

F. A. BATHER.

University and Educational Intelligence

CAMBRIDGE.—Prof. Owen Thomas Jones, Woodwardian professor of geology, has been elected to a professorial fellowship at Clare College.

At Trinity College, A. S. Besicovitch, University lecturer in mathematics, and L. Wittgenstein have been elected to fellowships.

The Appointments Committee of the Faculty of Geography has reappointed Miss M. S. Willis, of Newnham College, to be University demonstrator in the Faculty.

The Council of the Senate recommends the acceptance of the offer of the Council of the Royal Society to provide within three years a sum of £15,000 towards the building and equipment of a Laboratory for special physical investigations in the University of Cambridge, to be used in the first instance for magnetic and cryogenic research.

LONDON.—The title of emeritus professor has been conferred on Dr. Alice Werner, formerly University professor of Swahili and the Bantu languages at the School of Oriental Studies.

On the recommendation of the Board of Management of the London School of Hygiene and Tropical Medicine, Sir George Newman has been appointed Heath Clark Lecturer for the year 1931.

OXFORD.—Prof. A. Einstein will deliver the Rhodes Memorial Lecture for the year 1930–31; he will be in residence in Oxford during the next summer term.

ST. ANDREWS.—On the recommendation of the Senatus Academicus, the Court on Dec. 19 unanimously agreed to appoint Dr. David Lennox to be reader in forensic medicine, and Dr. W. L. Burgess to be reader in public health, in recognition of their long and distinguished service to the University as lecturers in these subjects.

Mr. George H. S. Milln was appointed lecturer in radiology and electrical therapeutics in the University, and Dr. David Jack to be a lecturer in natural philosophy in the United College, St. Andrews.

The Senatus Academicus has appointed Dr. R. R. Marett, Rector of Exeter College, Oxford, as Gifford Lecturer for 1931–32.

It was reported that the last Examination for the diploma and title of L.L.A. will be held in May next. The only candidates to be received are those who have already obtained part of the qualification and desire to complete it.

Birthdays and Research Centres.

Jan. 1, 1869.—Prof. A. A. T. BRACHET, For. Mem. R.S., Rector of the University of Brussels and director of the Laboratory of Embryology of the Faculty of Medicine in the University.

Le laboratoire d'Embryologie de la Faculté de médecine de Bruxelles suit principalement deux lignes de recherches. D'une part, l'analyse des localisations germinales et du déterminisme de la morphogénèse chez les Vertébrés, spécialement les Amphibiens; d'autre part, l'étude de la physiologie de la mise en marche du développement et des cinèses de segmentation.

Jan. 7, 1885.—Prof. A. J. ALLMAND, F.R.S., professor of chemistry, King's College, London.

The chemical laboratory at King's College is a comparatively small one, and the conditions, therefore, unfavourable for directed team work research towards pre-specified major objectives. But I believe firmly that almost any subject, if worked on pertinaciously and with reasonable skill, conscientiously (that is, with self-criticism), and with the desire for early publication strictly suppressed, may yield at any time results of real interest, even of importance. On this account, I would hesitate to say which I consider the chief investigation now in progress in this laboratory.

My students are working (1) at photochemistry, particularly at present on the effect of wave-length on the union of hydrogen and chlorine, as also on other reactions; (2) on the problem of the complete evaluation of the partial molal free energies in systems of the type lead chloride–alkali metal chloride–water; (3) on the sorption of vapours and gases by charcoal and other solid sorbents.

These investigations have all been in progress for years and have all proved sufficiently fruitful to satisfy us.

Jan. 8, 1856.—Prof. H. LECOMTE, professor of botany in the Paris Museum of Natural History.

Since his appointment to the professorship of botany in the Paris Museum, Prof. Lecomte has directed the work of the staff definitely to the study of Colonial floras, which were known before only in a fragmentary way. The "Flore Générale de l'Indo-Chine" was the first undertaken (1906); forty-four parts, out of about fifty it will comprise, have been already completed, with the devoted assistance of the scientific staff, of many Parisian botanists frequenting the Laboratory, and of professors from Paris and provincial universities. Besides, a great quantity of working material has been assembled and is ready to study for the preparation of floras of other French colonies: Guiana, Antilles, tropical Africa, Madagascar, New Caledonia. For some years past, and to complete this work, Prof. Lecomte has undertaken the anatomical study of tropical woods, of great interest from the point of view of the affinities it reveals, and also for the applications it enables one to foresee. Two important books have been published on woods of Indo-China and Madagascar.

Jan. 8, 1868.—Sir FRANK W. DYSON, K.B.E., F.R.S., Astronomer Royal.

A problem to which attention might usefully be given is the determination of the radial velocities of distant stars, such as those of early B type and those with the *c* characteristic in the southern half of the Galaxy. Dr. Oort has shown that the rotation of the system of stars round a point in galactic longitude l_0 would give rise to a term $Ar \sin 2(l-l_0)$ in their radial

velocities where r denotes the distance and A is a constant Prof Plaskett from observations of 250 stars finds $A = 17$ km per sec for a distance of 1000 parsecs and $l_0 = 325°$, but he could only observe four stars between the longitudes 193° and 343°, and until this lacuna has been filled up by observations in the southern hemisphere, this important result must be regarded as insufficiently verified

ROYAL ANTHROPOLOGICAL INSTITUTE, at 8 30 —J W Layard Malekula

WEDNESDAY, JANUARY 7

ROYAL SOCIETY OF ARTS, at 8 —H Barnard Ancient and Modern Pottery (Dr Mann Juvenile Lectures) (1)

INSTITUTION OF ELECTRICAL ENGINEERS (Wireless Section), at 6.—F. M. Colebrook and R. M. Wilmotte: A New Method of Measurement of Resistance and Reactance at Radio Frequencies.—E. B. Moullin: A Variable Capacity Cylindrical Condenser for Precision Measurements.

INSTITUTION OF HEATING AND VENTILATING ENGINEERS (at 20 Hart Street, W.C.1), at 7.—C. G. H. Hallett: Notes on the Theory of Radiant Heating.

ELECTROPLATERS AND DEPOSITORS TECHNICAL SOCIETY (at Northampton Polytechnic Institute), at 8.15.—Modern Metal Cleaning.

ROYAL SOCIETY OF MEDICINE (Surgery Section), at 8.30.—Pathological Evening.

THURSDAY, JANUARY 8.

INSTITUTION OF MUNICIPAL AND COUNTY ENGINEERS (Northern Irish District) *(at Town Hall Bangor), at 3.—G. H. Fleming: Urban Works.*

ROYAL INSTITUTION OF GREAT BRITAIN, at 3.—Prof. A. M. Tyndall: The Electric Spark (5): Some Properties of Sparks and Arcs (Juvenile Lectures).

LINNEAN SOCIETY OF LONDON, at 5.—Prof. E. J. Salisbury: A Study of *Ranunculus parviflorus* L. with Special Reference to its Morphology and Ecology.—H. W. Pugsley and A. J. Wilmott: New British Plants.

INSTITUTION OF ELECTRICAL ENGINEERS, at 6.—C. E. R. Bruce: The Distribution of Energy liberated in an Oil Circuit Breaker with a Contribution to the Study of the Arc Temperature.

ROYAL AERONAUTICAL SOCIETY (at Royal Society of Arts), at 6.30.—A. Gouge: Some Aspects of the Design and Construction of Sea going Aircraft.

INSTITUTION OF ELECTRICAL ENGINEERS (at Loughborough College), at 6.45.—E. G. Clark and G. Fowler: The Consumer's Point of View.

INSTITUTION OF AUTOMOBILE ENGINEERS (Bristol Centre) (at Merchant Venturers Technical College, Bristol), at 7.—E. V. Pannell: Light Alloy Piston Development.

ROYAL PHOTOGRAPHIC SOCIETY OF GREAT BRITAIN (Colour Group—Informal Meeting), at 7.—Discussion on Faults and Failures in Colour Photography.

SOCIETY OF CHEMICAL INDUSTRY (Bristol Section) (at University, Bristol), at 7.30.—E. A. Ashcroft: Electrolysis of Fused Zinc Chloride.

NORTH EAST COAST INSTITUTION OF ENGINEERS AND SHIPBUILDERS (Tees side Branch Graduate Section) (at Cleveland Scientific and Technical Institution, Middlesbrough), at 7.30.—J. R. Cone: Ironwork Practice.

INSTITUTE OF METALS (London Section) (at 88 Pall Mall), at 7.30.—R. Genders: Extrusion.

OIL AND COLOUR CHEMISTS' ASSOCIATION (at 30 Russell Square), at 7.30.—Dr. T. H. Durrans: Solvents.

INSTITUTION OF WELDING ENGINEERS (at Institution of Mechanical Engineers), at 7.30.—*H. D. Lloyd and J. S. G. Primrose*: The Use of Pure Iron Electrodes for Welding Cast Iron.

FRIDAY, JANUARY 9.

ROYAL GEOGRAPHICAL SOCIETY, at 3.30.—Dr. C. M. Yonge: Life on the Great Barrier Reef (Christmas Lecture for Young People).

ROYAL SOCIETY OF ARTS (Indian Section), at 4.30.

ROYAL ASTRONOMICAL SOCIETY, at 5.

MALACOLOGICAL SOCIETY OF LONDON (at Linnean Society), at 6.

INSTITUTION OF ELECTRICAL ENGINEERS (London Students' Section), at 6.15.—A. Dean and M. M. Macmaster: Mercury Arc Rectifiers.

OIL AND COLOUR CHEMISTS' ASSOCIATION (jointly with Society of Chemical Industry, *Literary and Philosophical Society* and *Society of Dyers and Colourists*) (in Psychology Department, University, Manchester), at 7.—W. O. D. Pierce: Human Factors in Colour Judgment.

JUNIOR INSTITUTION OF ENGINEERS, at 7.30.—J. Doonan: Monel Metal: Some Notes on its Production and Industrial Application.

GEOLOGISTS' *ASSOCIATION* (in Botany Theatre, University College), at 7.30.—Special General Meeting.

SATURDAY, JANUARY 10.

ROYAL INSTITUTION OF GREAT BRITAIN, at 3.—Prof. A. M. Tyndall: The Electric Spark (6): Large Sparks (Juvenile Lectures).

PUBLIC LECTURES.

TUESDAY, JANUARY 6.

UNIVERSITY OF LEEDS, at 6.—Prof. W. Garstang: Life in the Sea.

WEDNESDAY, JANUARY 7.

MUSEUM AND ART GALLERY, BELFAST, at 8.—F. Rutter: Modern British Art.

CONFERENCES.

DECEMBER 31 TO JANUARY 5.

GEOGRAPHICAL ASSOCIATION.

Friday, Jan. 2 (at London School of Economics).

At 10 A.M.—Major R. W. G. Hingston: In the Tree Roof of the Guiana Forest (Lecture).

At 11.30 A.M.—*Miss R. M. Fleming: Regions of Russia* (Lecture).

At 2.30.—Meeting for Teachers in Secondary Schools for Discussion on a paper by B. C. Wallis on School Geography from the Point of View of an Examiner.

Meeting for Teachers in Primary Schools.—Geography and the Extension of the School Age. *Discussion to be opened by E. J. Orford.*

Saturday, Jan. 3 (at London School of Economics).

At 10.15 A.M.—Dr. P. W. Bryan: The Distribution of Houses in England and Wales as a Population Index (Lecture).

DECEMBER 31 TO JANUARY 7.

CONFERENCE OF EDUCATIONAL ASSOCIATIONS (at University College).

DALTON ASSOCIATION.

Friday, Jan. 2, at 11.—G. W. Spriggs: Individual Work in Mathematic (Lecture).

MEDICAL OFFICERS OF SCHOOLS ASSOCIATION.

At 2.—Dr. A. G. Maitland Jones and others: Discussion on Hour of Sleep and the School Child in Day and Public Schools.

CHILD-STUDY SOCIETY.

At 5.30.—Prof. J. E. Marcault: What is Religious in the Child (Lecture).

MODERN LANGUAGE ASSOCIATION.

Monday, Jan. 5, at 11 A.M.—Prof. E. W. Scripture and Prof. P. Menzerath: Discussion on Experimental Phonetics.

NATIONAL COLLEGE OF TEACHERS OF THE DEAF.

At 11 A.M.—Dr. J. Drever: The Educational Handicap of the Dea *from a Psychologist's Point of View (Lecture).*

JOINT CONFERENCE.

At 5.—J. Fairgrieve, Lt.-Gen. Sir William Furse, Miss B. Hosgood, C. B. Thurston: The Teaching of Geography. Chairman: Sir Richar Gregory.

CENTRAL COUNCIL FOR SCHOOL BROADCASTING.

Tuesday, Jan. 6, at 11 A.M.—Prof. Winifred Cullis and others: Th Teaching of Biology by Wireless (Lecture Demonstration).

BRITISH SOCIAL HYGIENE COUNCIL.

At 5.—Dr. H. Crichton Miller: Marriage, Freedom, and Educatio (Lecture).

JANUARY 5 AND 6.

MATHEMATICAL ASSOCIATION (at London Day Training College).

Monday, Jan. 5, at 3.30.—Sir Arthur S. Eddington: The End of th World (from the standpoint of Mathematical Physics) (Presidentia Address).

At 5.—Prof. A. R. Forsyth: Dimensions in Geometry.

Tuesday, Jan. 6, at 10 A.M.—A. Robson and others: Discussion on Th Report on the Teaching of Mechanics in Schools.

At 11.30 A.M.—W. Hope-Jones, Dr. F. J. W. Whipple, P. M. Marples and others: Discussion on Gambling.

At 2.30.—Prof. J. E. A. Steggall: Faith and Reason in beginning th Calculus and Elsewhere.

At 3.45.—Prof. E. H. Neville: Limits in Geometry.

JANUARY 6 TO 9.

SCIENCE MASTERS' ASSOCIATION (at University, Birmingham).

Tuesday, Jan. 6, at 8.30 P.M.—Sir Charles Grant Robertson: Presidentia *Address.*

Wednesday, Jan. 7, at 10.15 A.M.—J. Young: The Lunar Landscap (Lecture).

At 11.30 A.M.—Prof. W. N. Haworth: An Insight into Comple Molecular Structures (Lecture).

At 6.—*Prof. Nash: The Work of the Physicist and Chemist in th* Petroleum Industry (Lecture).

At 8.15.—The Lord Bishop of Birmingham: A Finite Universe (Lecture).

Thursday, Jan. 8, 10 to 11.15 A.M.—F. Fairbrother and others: Discus sion on General Science.

At 12.—Prof. K. N. Moss: Scholarships offered in Coal Mining an Metal Mining.

6 to 7.15.—Prof. F. W. Burstall: The Science Education of the Bo up to Eighteen Years of Age (Lecture).

At 8.30.—Meeting of S.M.A. with Representatives of the Commis sion on Educational and Cultural Films.

Friday, Jan. 9, at 10 A.M.—Prof. H. Munro Fox: Zoological Experi ments for School Work.

EXHIBITION.

JANUARY 6 TO 8.

PHYSICAL AND OPTICAL SOCIETIES' EXHIBITION OF ELECTRICAL, OPTICAL, AND OTHER PHYSICAL APPARATUS (at Imperial College of Science an Technology), at 3 to 6, and 7 to 10.

Wednesday, Jan. 7, at 8 P.M.—E. Lancaster Jones: Searching fo Minerals with Scientific Instruments (Lecture).

Thursday, Jan. 8, at 8 P.M.—Sir Gilbert Walker: Physics of Spor (Lecture).

The Protection of Scientific Property.

THE debate on the protection of scientific property at the last session of the Sub-Committee on Intellectual Rights of the International Committee on Intellectual Co-operation gained special interest from the presence of two members of the Italian National Committee, who submitted a memorandum suggesting substantial amendments to the preliminary draft Convention of Dec 14, 1927 This draft Convention, which was presented to the Assembly of the League of Nations in September 1928, proposed to create by means of an International Convention and a corresponding Union a new right, leaving the existing structure of patent law and copyright untouched The Convention is designed to secure for the authors of scientific discoveries participation in the material profits arising from their industrial exploitation

Scientific discoveries which entitle their authors to receive remuneration from the users of the discovery must fulfil two conditions

(1) They must be open to material utilisation, in the sense that they contribute to the production of a commercial commodity , and

(2) They must lead to new means of production or new applications of existing means of production Discoveries which are explanations of existing practice and purely retrospective in their application are thus definitely excluded, although of course they may strengthen industrial practice and increase its confidence

In the second part of the Convention, the rights and obligations of the authors are defined, and in doing so, a distinction is made between the creation or recognition and the exercise of the right While the rights of the author are derived from the unequivocal publication of the discovery, the exercise of these rights as against the users of the discovery is declared to be effective only as from the date of the registration, by an international organisation, of the deposit of a note claiming for the author the right defined in Article 1 over material applications of the discovery Thus, in a dispute between two authors, priority may be established by the production of *any* document of unquestioned date, but in a dispute between author and users, the *only* lawful proof which can be adduced against the users is a note registered with an international organisation and accompanied by specified claims with reference to the practical application of the discovery a result which would probably be achieved by the creation of a new bureau on the lines of the Berne Bureaux of Industrial, Literary,

and *Artistic Property* *The restriction of the exercise of the right to this condition on international* registration under specific conditions of publicity meets a perfectly legitimate stipulation on the part of manufacturers if they are to incur liability or obligations

Part III of the Convention defines the rights and obligations of the user, and distinguishes clearly between the new right and patents The new right confers no monopoly of exploitation, any undertaking may use the discovery, subject only to payment to the authors of a consideration, the nature of which is to be fixed either by free agreement between the authors and users, or failing such agreement, by judicial procedure It is, of course, quite possible that a dispute may arise between men of science as to priority when the discovery is already receiving industrial exploitation Article 12 of this section accordingly endeavours to secure that the industrial exploitation shall go on unhindered while the dispute is fought out, and a concluding article, inserted to ensure that the terms of contracts shall not destroy the legitimate expectations which the Convention arouses in the minds of discoverers, asserts that all private agreements which are contrary to the provisions of the Convention shall be deemed null and void, as being prejudicial to the public order

On behalf of the Italian Committee, M Piola Caselli and Prof G Bruni (professor of general and inorganic chemistry at the Royal Engineering School at Milan) suggested the addition to Article 4 of a stipulation that the note claiming the right must be deposited within three years from the date of publication from which the right is derived, and further that the right should be limited to the duration of the inventor's patent instead of to the term of thirty years contemplated in Article 10 Further recommendations were made that the remuneration should be determined by the courts of the user's country, rather than by an international court of arbitration, and provision made for cases of joint discovery

These proposals, while not receiving the full assent of the Sub-Committee, were referred to the different national committees for further discussion and criticism, whilst awaiting from governments their observations on the draft Convention and the accompanying note which has been drafted by the mixed committee of insurance and legal experts

The present position is, accordingly, that a Convention has been submitted to the various governments for consideration, and this has been accompanied by a note contemplating the establishment of a system of guarantees for users of scientific discoveries, in the form either of mutual insurance or compensatory funds or both, and eventually the establishment of a fixed scale of insurance premiums in private companies

This note is the outcome of the criticism of the draft scheme from industrial opinion, notably in the United States of America and in Germany, which indicated that the Convention would only be acceptable if accompanied by a note guaranteeing industrialists, through some system of insurance, against fresh liabilities arising from royalties due to men of science and inventors The uncertainty of the representatives of British, French, and other insurance companies regarding the nature and extent of the risks which they might be called upon to assume under the proposed liabilities led to the convening of a small committee of insurance and legal experts, which met in Paris in December 1929 and March last and drafted the note to which reference has been made

Meanwhile the fundamental idea of scientific property gains ground every year, and the absence of protection for scientific or theoretical discoveries is recognised more widely as not merely anomalous, but also unjust Mr F H Carr, for example, in a presidential address to the Society of Chemical Industry, referred to the desirability of finding methods of remunerating those who have contributed to industrial invention by researches freely published in scientific journals While the bulk of the controversy over the proposal of the Patents Committee of the Association of British Chemical Manufacturers regarding "dedicated patents" has centred round the efficacy of the protection they offered for the fine chemical manufacturer during the expensive development work required before chemical or biological products of this type can be marketed, the right of the discoverer to some reward has not been overlooked. As Senator Ruffini pointed out in his original report, the only result of withholding protection from therapeutics, as in the French and Italian patent systems, is that the industrialist is allowed to exploit the invention advantageously through the trade mark or registered name device, reaping the reward which might otherwise have fallen to the man of science, at least in part, the advantages to the public health are purely imaginary

There are, indeed, those who, prompted by the growing evil of 'paper patents' created, notably in industrial chemistry, by the intelligent forecast, question the suitability of our whole patent system,

with its basis of invention, to a modern industry in which the major advances are now almost always the result of organised scientific research and team work in which individual inventive ability or ingenuity plays a subsidiary part.

The present system admittedly refuses protection to a scientific discovery of first-class importance, and it is often impossible in a mass of patents to sift out the true knowledge from mere predictions which may or may not be verified by experience Consequently, the public receives no real disclosure in return for the protection In such circumstances, while the industrial research worker remains outside the Convention, any measure which encourages the growth of scientific research by offering real reward to scientific discoveries may be of real benefit to industry At least some sections of industry to-day owe their difficulties in part to a lack of contact between their technical staff and workers in pure science Fundamental scientific research remains the most important fertiliser for industrial research and development, and with the increasing mechanisation of our daily life and the intensive exploitation of the world's resources, its importance will become ever greater

The use of the term 'Scientific Property' in the draft Convention is perhaps something of a handicap It is liable to give a misleading impression and, in the opinion of some, its use has constituted an obstacle to progress, the word 'property' having caused apprehension among manufacturers At the last session of the International Committee, the use of such expressions as "the right of the scientist to his discoveries" or "in the remunerative utilisation of his discoveries" found powerful advocacy, but in view of the general use of the expression and its connexion with the established terms 'Artistic Property', 'Literary Property', the Committee, however, decided that a change was inadvisable, if not impossible, now that the Convention had been drafted

The Italian National Committee has set an example which might well be followed by others The idea of protecting scientific property has been raised at an opportune time, and the six years or more which have elapsed since the inquiry and study of the subject were first commenced is none too long a period It is to be hoped that the question will receive closer attention in Great Britain than has yet been the case, and that there will be no attempt made to curtail discussion or precipitate a decision by this or other governments regarding a Convention which may, indeed, prove impracticable, but may equally prove a valuable stimulus to scientific research and discovery

The Anatomy of History.

Human History By G Elliot Smith. Pp. 509. (London Jonathan Cape, Ltd, 1930) 21*s*. net

TWO problems, above all, have engaged the attention of thinking men, since man first began to think the 'riddle of the universe' and the 'meaning of history' The study of each has come to have its proper technique and discipline But central in one, and conspicuous in the field of the other, stands man himself the 'proper study of mankind' is at the same time anthropology and *literæ humanissimæ* Like the 'man in the street', with his guesses at 'what we are and whence we came', the anatomist, too, "cannot help puzzling over the behaviour of his fellows" and studies "the dead past of man and his strivings", mummification, gold-quest, warfare, and the like, "as a means of interpreting the living present"

The philosophy of history, as Dr Elliot Smith, in the light of his special skill, expounds it, is a simple one "it would not be an exaggeration to say that civilisation was evolved out of man's endeavours to understand the constitution of his own body and to preserve the life that animated it" Taking account of recent discoveries about primitive man, his early civilisations, the 'legacy of Greece', and prehistoric Europe, his object is "to search for the deep motives that have shaped man's career, and to call attention to the vital factors in human thought and behaviour, which have been ignored by most writers" (p 13)

Among these "vital factors", on which the "fabric of civilisation" was built up, he reckons "ideas of the function of the heart and blood, the breath and moisture, the placenta, and the hypothetical 'life substance'" (p 13) He thinks that "all man's early nature-studies were self-centred and in the last resort were related to the expressions of life in his own body" A similar notion underlay the "Physical Realism" of the late Thomas Case, but that was not circulatory philosophy, but muscular, as became one who was a cricketer, not an anatomist Whither, then, does this transcendental omphaloscopy lead us? What is the meaning of "Human History"?

To appreciate the argument, account must be taken of the author's "new emphasis on the fact of the continuity of culture both in time and space", on which, however, he has repeatedly insisted elsewhere What the "principle of continuity" explains in geology and biology, the "tyranny of tradition" effects in "Human History" Yet there was apparently a catastrophe, somewhere

and somewhen for whereas "primitive men were decent, generous, and peaceful", mankind has, alas! somehow "acquired culture, and with it social unrest, dangerous practices, and methods of cruelty" An earlier exponent of the same theme ascribed the Fall to an apple After reading "Human History", one suspects the placenta

Broadly, then, human history is a drama in three acts With two of them, other writings of Dr Elliot Smith have already made us familiar, but the restatement of his views is welcome, not least as an illustration of that 'continuity' through which ideas, essentially the same, become *diablement changés en route* For amid the "tyranny of tradition" we have glimpses of mute inglorious inventors, outside early Egypt, and antecedent, the Chellean method of flint-chipping, which "originated in one spot, where a pioneer invented it" (p 95), the "relatively slight change necessary to attain such greater efficiency" as distinguishes Acheulean technique from Chellean (pp 97, 115), and then "a new genius arose and invented the technique known to us as Mousterian" (p 97) What a pity that the new material from the Bambata Cave in Southern Rhodesia comes just too late to illustrate, in thousands, the "relatively slight changes" necessary to replace traditional Mousterian into a specific local 'industry'! What an instance of 'continuity' defeating 'tradition', and how difficult, except for a biologist, to distinguish this from "some process of so-called evolution", which by mere "tyranny of tradition" still means for many people, since the publication of the "Early History of Mankind" and the "Evolution of Culture", the survival of the fittest among "slight changes necessary to attain such greater efficiency" innumerable and ubiquitous, and we may note that it is on the morrow of such momentous pause in the record as marks the geological 'continuity' between Chellean and Acheulean gravels that the new theory postulates one "individual of outstanding genius", to make all the difference between Chellean and Acheulean technique

So too, among uncompromising denials of the influence of geographical surroundings on mankind (p 253), there are significant admissions Though the "pronounced monogamy of the Food-gatherers" awaits explanation, "economic causes may well play a part It may not be possible for a man to keep more than one wife" (p 263) The Melanesians (p 157) "probably only reached new islands when they were swept by the forces of Nature out of their course". Worse follows, "it may also be something more than a coincidence that the Hittites arose on the edge of the salt treeless tract in Central Asia Minor" (p 287) Worst of all, "the natural crop of barley, which was growing wild on the banks of the Nile, seems to have provided the lure to attract the earlier settlers in Egypt" (p 272), and though, of course, "some man of exceptional insight imitated the natural processes", the vital importance of irrigation "impelled the Egyptians to study the habits of their river" (p 278), and "hence communities became herded together in villages, and people were forced into more intimate association", wore clothes, buried their dead, and set out on the 'life-quest' and all our woe, all unaware that geographical facts such as "the habits of their river" were incompetent to modify the habits of a people Or was some "individual of outstanding genius" the first to scramble up the bank to keep his feet dry? In fact (p 291), "we may draw the only possible inference and assume the invention of agriculture in Egypt, where Nature was annually pointing the way so clearly" A very naughty river, to break the 'continuity' of human history so!

More generally still, among mammals, "those which wander away from their original home and become subjected to new environment and new conditions of life, new food to search for, and new dangers to overcome, are more rapidly transformed than those that stay at home" (p 159), and this is explicitly applied to Mediterranean man Change of scene seems, after all, to suit those "individuals of outstanding genius" whose breaches in the "tyranny of tradition" illustrate the "principle of continuity" in biology Instances abound in "Human History"

"The first hunting-grounds were only attractive if flint was to be found near them" (p 95) "the increasing cold must have tried these roaming hunters severely", and "in the Acheulean strata are the ashes of the first hearths" (p 96) So ancient is the habit, universally diffused to-day, of "borrowing a light" But who borrowed first, and from whom? Or did more than one 'pioneer' strike a light while striking a flint? Even among 'grassland' man—a particular *bête noire* of continuous history—"the population was kept small by the exigencies of the rainfall alone" In Greece itself the emancipation of human reason was not quite complete, for this country (p 431) had been "continually subjected to the cultural influences diffused in the waters that bathed its shores", an interesting glimpse of the physics of diffusion

Another very welcome shift of view is the generous

recognition of Tylor's "luminous expression" of the "principles that should inform any attempt to interpret the behaviour of men under conditions of civilisation" True, the old leaven festers still, in the reference (p 329) to a "theory of universal animism which distorted the vision of ethnologists for more than half a century" But as it is admitted that Tylor "discovered so many examples of a peculiar phenomenon the attribution of life and mind to inanimate objects", we are not far from the view that a certain outlook on human history, like Chellean flint-chipping, "originated in one spot, where a pioneer invented it"

For the Fall to have had such disastrous consequences—"social unrest, dangerous practices, and methods of cruelty"—the state of innocence must have been innocent indeed, and the rehabilitation of the 'noble savage' is one of the more important of Dr Elliot Smith's contentions For if civilisation, with all its evils, has resulted from man's endeavours "to understand the constitution of his own body and to preserve the life that animated it", what risks we run from the teaching of physicians and anatomists! What is odd, however, is that the "decent, generous, and peaceful" food gatherers should for millennia and with such uniformity (or was it 'continuity'?) have missed the significance of the placenta for it is admitted (p 330) that "the study of the phenomena of birth is as old as man himself" As is insisted in the same context (p 329), "even serious investigators by pushing just a little further than the evidence warrants the application of a bright idea, can make it nonsensical" and the reviewer craves pardon in advance, if he has played the pioneer in that way But is the evidence as to the distribution of placenta-cults, or flag worship, or other "dangerous practices", so complete as to justify inferences from presumed lack of them among "food-gatherers", or the complementary conclusion that the occurrence of practices resembling them results from diffusion of food-producing culture among peoples who do not in fact produce food?

The stress justly laid on the regional character of the Upper Palæolithic cultures—in spite of the corollary presumably postulating regional pioneers'—makes more surprising Dr Elliot Smith's insistence on the brevity and insignificance of the phrases usually described as Neolithic, "anywhere except in Britain and western Europe" That the "real revolution" was the replacement of *H neanderthalensis* by *H sapiens* may be admitted, without overlooking the significance of the new technique of grinding and boring In the Philippines, for example, there is stratigraphical evidence for two well-marked cultures with more or less 'polished' implements, accompanied by pottery, between the Upper Palæolithic and the Iron Age layers Here it is not the Neolithic that is absent but the Bronze Age, which means so much to Dr Elliot Smith But, as he admits in another context (p 106), "so again in the Neolithic Age a succession of new waves of population intruded from time to time, each bringing some new contribution"

There is, however, a reason for this apparent neglect of Neolithic phases Unless the very short duration here assigned to them, particularly in the north-west, is admitted, it is difficult to establish the remarkable precocity of culture in Egypt, which is central in Dr Elliot Smith's interpretation That many elements of European civilisation spread from the Near East, is admitted The question is whether other parts of the Near East themselves obtained them by 'diffusion' from Egypt, and as, until lately, the chronological inferences, from sequence dating and stratigraphy combined, were better supported in Egypt than elsewhere, it is obvious that *if* these arts and practices originated in Egypt, their first appearance elsewhere should be subsequent This, however, is just what has to be proved, and the very confident statements of Egyptian priority in "Human History" are not accompanied by evidence more conclusive than what has been so variously interpreted In particular, the geographical distribution (or is it 'diffusion'?) of apparently wild congeners and precursors of the earliest cultivated grain plants cannot really be said to be fully established yet, and in so far as it is approximately known, it seems generally taken to favour Asiatic origin for cultivated grains Since this question of grain crops is as fundamental to the Osirian theory of civilisation as the placenta-cult itself, readers of "Human History" must prepare themselves for another act of faith

Nor is the "ancient tradition of Osiris recorded by Plutarch" more valuable corroboration of the hypothesis of an "individual of outstanding genius" at the beginning of Egyptian civilisation, than is Archbishop Usher's approximation to Prof Breasted's date for this modern version of the Fall For if the Egyptians were "living the life of Natural Man before they began their pioneer work", Osiris lived before the first potter, and this helps to explain a certain reluctance to grant high antiquity to the Badarian precursors of pre Dynastic pottery But Osiris is represented (p 253) as

having made his amazing innovations not much earlier than 4000 B C What, then, becomes of the ceramic priority of Egypt ? For the correlation of this phase of its culture with the Cretan series is at the top, not the bottom, of the twenty feet of pot infested house-debris which underlies the first Bronze Age layer And is not the admission (p 279) that "like all human communities throughout the ages [the Egyptians] listened to the voice of authority", rather destructive of the view that it was because they were the first people to do so, that they involved themselves, and us all, in the 'dangerous practices' of civilisation ?

Among these practices, as has been noted already, those based on observation of vital processes are represented as of central significance Here a strong case is presented for regarding this whole group of beliefs and customs as concerned less with the reproduction of life, by so-called 'fertility' rites, than with the maintenance and enhancement of existing life—the life of the performer, or of someone whose continued existence seemed indispensable to him This is a fresh and fertile suggestion, which it would be impossible to discuss adequately here, further than by noting how that notion gained new and tremendous vogue, as soon as efforts to maintain and enhance were transferred from *this* life to another, and men distinguished the transcendental maintainer of life from their own temporal chieftain The relation of this view of early culture to those propounded already in Christopher Dawson's "Age of the Gods" and Hocart's "Kingship" will be obvious

At last the curtain rises on Act III Dr Elliot Smith has discovered the Greeks More precisely, he has gone a step further than Ure's "Origin of Tyranny" That was itself a venturesome book, wherein the invention of coinage, and the mobility thus given to wealth, were claimed as the material cause of that emancipation of individual enterprise from restrictions of communal ownership which in turn made possible the democratic movement in Greek city-states, with all that this implied Dr Elliot Smith's corollary is that there was concurrent emancipation from the "tyranny of tradition" in the world of thought, with the result that "mankind recovered intellectual freedom", even if people still do not always avail themselves of it to rationalise their lives Yet mark the tragedy, that so high an achievement of this people of "transcendent genius" should be correlated in 'Human History" with such a merely geographical accident as the occurrence of gold in the Pactolus river !

Not that 'continuity' was lacking even here Dr Elliot Smith has satisfied himself that there was "no break in the development of style" between Mycenæan and geometrical art (p 431), also that the Doric column was "derived ultimately from Egypt" because "all later fluted columns must be derived ultimately from these Third Dynasty types" Such was the "tyranny of tradition" until the invention of coinage, though Dr Elliot Smith is insistent that it did not apply to round pillars, nor to square (p 451), which "given the idea of a pillar, might arise independently in any country and any number of times" But why ? Are "individuals of transcendent genius" so common in the building trade ?

But if Greece learned Egyptian notions by 'diffusion', it also taught that way It is "an excellent illustration of the general theorem of the diffusion of culture", that "Greece provided most, if not all, the principles which distinguish" not only "the higher culture of Western civilisation" but also "those of Asia and pre Columbian America" This leads straight to the thesis of the author's "Elephants and Ethnologists", but with greater insistence on the Hellenic (and therefore ultimately Egyptian) source of the "connexions between the Ægean, Scythia, and India" and therefore of "results which hitherto have been unduly minimised, if not wholly ignored" (p 462) Thus we have "clear evidence of Cretan influence in Turkestan in Middle Minoan times" (p 467) which will be news to the specialists That Ionian rationalism may have inspired the 'rational philosophy' of the Buddha, has been suggested by others, what is less easy to accept is that "there was no architecture in India till the advent of Buddhism" (p 472), especially as the ancient cities at Harappa and Mohenjo-Daro are mentioned immediately after Eventual limitation to *stone* architecture (p 474) is further qualified by excluding not only the stonework on those northern sites, but also the 'megaliths' of southern India, and the claim for Hellenic initiative would seem to fail, in face of evidence for Achæmenid models (p 476) The case is indeed given away on p 477 "could we discover what the wood carving was like" which dominates early Indian stonework "we should be more certain of the history of early Indian art As it is, we can only judge from the surviving stone reliefs" It is admitted also (p 476) that the 'honeysuckle' and other ornaments common in Greek architecture "were employed in earlier Assyrian" as well as in Persian Is it true, further, that the halo is "used in Greek

paintings as an attribute of gods" (p 479) before Christian times?

Such perplexities may result from the condensation evident in this latest section of "Human History", and the survey of events in the west, and Greek influence on Christian and Moslem thought, is more summary still But in the plan of the book there is a reason for this It was the achievement of the Greeks "to restore to human reason the freedom it had lost" when man "began to devise civilisation" and "became entangled in the shackles of the theory of the State" (p 497) The "conflict between the rationalism of Hellas and the superstition of Egypt" is, however, not over In the words of Dr Elliot Smith's epilogue, "it depends on the human population of the world themselves, which will win For thought and courage can decide the issue" Of both there is abundance in this book, which is appropriately dedicated to the "vision and courage" of another "pioneer", Dr W J Perry J L MYRES

Wind and Water

Wind and Water By Manfred Curry Pp 28+120 plates (London *Country Life*, Ltd, 1930) 25*s* net

THIS is a handsome quarto volume of one hundred and twenty full-page photographs, the first half of which are studies of sea and lake, the second half of sailing yachts The plates are a selection made by Mr Curry from many thousands taken by various photographers The smooth paper on which they are reproduced is free from pernicious glaze and restful to the eye

Some of the wave studies are of exceptional merit One by F S Schensky showing the back of a wave rushing on the cliffs of Heligoland admirably conveys the speed of the surge, and another by the same photographer of the front of a great breaker (presumably on the same shore) is an effective counterpart The combing crest rises above the sky-line and is cambered in the centre The moment of exposure of the plate has been exactly timed for the closing of the cusp upon the cushion of water in front, a critical moment seldom recorded

Of the lake studies, two stand in happy contrast The first is of Lake Constance in a Föhn wind, with lines of breakers below and long rolls of stormy cloud above, separated by the serrated summits of a mountain range—a beautiful composition The second is of a tarn in Switzerland, in the clear waters of which the mountains

View the stillness of their aspect

more perfectly than is possible in the larger lakes fed by the turbid waters of a glacier stream. The study of the Walensee is an effective rendering of a contrast which always exercises an imaginative appeal—that of a vertical cliff of massive rock with the level lines of smooth water and a low shore in the distance

There are two fine photographs taken at sea, both by Count Larisch, one of which shows the rush of a single wave rising high above the line of sight, the other a remarkable effect of rigging and spars, and a heeling deck awash in a heavy sea

A number of photographs of yachts sailing will be of interest to those versed in the sport, but are for the most part lacking in pictorial effect

The introductory letterpress is in two sections, of which the first and longer relates to waves and wind Mr Curry refers to his discoveries about waves He has indeed made observations and formed opinions, but I venture to suggest that a further study of the work which has been published upon this difficult subject would lead to a modification of the views which he advances, particularly in regard to the preponderating importance which he attributes to the friction of wind in the formation of waves and the friction of the sea bottom in deflecting their direction in the neighbourhood of the shore

With the comments of the author upon the relation of modern aerodynamics to yachting I am not competent to deal, and of this section of the introduction I can only say that Mr Curry's enthusiasm for his sport makes agreeable reading even for one who is not a practical yachtsman

VAUGHAN CORNISH

Mars 226591

Le planete Mars etude basée sur les résultats obtenus avec la grande lunette de l'Observatoire de Meudon et exposé analytique de l'ensemble des travaux exécutés sur cet astre depuis 1659 Par E M Antoniadi Pp iv+240+10 planches (Paris Hermann et Cie, 1930) 80 francs

THIS is unquestionably one of the most important books on Mars ever published, and it will always remain a standard work of reference for the period covered by the author's researches

The book opens with a chapter on the planet in antiquity which illustrates the writer's wide knowledge of the literature and astronomy of ancient times But it is especially with our knowledge of Martian topography as revealed by the telescope that it is concerned, and Chap ii contains an account of instruments, stations, and conditions

most favourable for a successful study of this interesting planet It will be noted here that M Antoniadi—who first in 1909 had the immense advantage of using systematically for the study of Mars the great 32 7 in refractor of the Meudon Observatory, through the kindness of Dr H Deslandres (then its Director), to whom this book is fittingly dedicated—himself prefers refractors to reflectors, but it will be something of a surprise to some readers to find that he does not consider the secondary spectrum a serious drawback in the use of such instruments for planetary work The view of Prof Ritchey, which he quotes, that an important factor in the success of the Meudon telescope is the height of the object glass above the surface of the ground, is doubtless correct Indeed, it has long seemed to the reviewer that the unsteadiness of the images so often given by reflectors—especially when employed in the open —arises largely from the fact that their specula are situated in the disturbed conditions near the ground level, as well as from the usual tube currents Foggy weather, of course, naturally finds approval where large apertures are to be used, as also does a considerable altitude with the view of getting above the denser strata of the atmosphere, but the habit of employing diaphragms to improve the steadiness of the images is strongly criticised as seriously diminishing the separating power so essential in the resolution of planetary details

The following chapter contains details of the orbital and physical elements of Mars, after which we come to a general account of the surface features as telescopically observed, including changes of colour, " the illusion of the canals ", the polar caps, clouds and other atmospheric phenomena, the habitability of the planet, and the two satellites This concludes the first part of the volume

Part 2 consists of a very full and detailed descriptive account of the planet's surface, and the changes, seasonal and otherwise, which have been observed to take place in the several markings These details are well illustrated by a number of drawings, mainly by the author The nomenclature employed is that of Schiaparelli, but this has been extended by the adoption of names from the maps of Lowell and Cerulli, and in the case of a number of more recently detected features the names have been assigned by M Antoniadi himself

It is to be noted that in general this descriptive part of the volume is intended mainly as a presentation of the author's own researches, but the history of our knowledge of the various features is carefully traced from earlier records and supplemented by the work of contemporary observers Great care has been taken in the selection of the material presented, and there are abundant references to the work of members of the Mars Section of the British Astronomical Association, of which M Antoniadi was for several years the director

Of course, the great value of the work lies in the fact that it presents the conclusions of a particularly able and accurate observer using one of the very best instruments in the world, and, moreover, one who possesses very great skill as a planetary draughtsman It will be clear to the reader that its inspiration lies in the wonderful views of Mars shown to the author by the great telescope at Meudon in 1909 It was these views which led to his final conviction that the so-called ' canals ' of Schiaparelli and Lowell were illusory, in the sense that their geometrical appearances, together with such phenomena as their occasional gemination, were the result of optical and physiological causes In particular, the straight and linear appearance of many of these features was announced as nothing more than a consequence of integration by the eye of irregular spots and markings which were in general beyond the reach of distinct vision with the relatively small apertures usually employed up to that time That there is some objective basis behind the Schiaparellian canals is, of course, fully recognised This is illustrated in the chapter on " The Illusion of the Canals ", and for further details the reader may turn to the 1909 Report of the Mars Section of the British Astronomical Association published in vol 20, part 2, of the *Memoirs* The previous scepticism concerning the reality of these geometrical features will be well remembered. While some assiduous and trustworthy planetary observers using instruments of moderate size recorded a number of them, there were others, such as N E Green, E W Maunder (see a paper in *Mon Not Roy Ast Soc*, vol 63, p 488, by E W Maunder and J E Evans), and Cerulli—to mention just a few—who consistently maintained that they were capable of an optical explanation It was, however, the great Meudon refractor which actually showed to M Antoniadi in 1909 those irregular spots and broken up features into which the canal system is so very largely resolvable when adequate telescopic power is employed

There is, however, one point to which it seems needful to direct attention in order to avoid further confusion Most unfortunately, ever since the days of Schiaparelli, markings of very different characteristics have been designated ' canals ', namely, broad dark streaks on one hand and fine spider-web-like

lines on the other This is partly attributable, no doubt, to considerable changes in the intensity and breadth of some of these markings, but so long as the term 'canal' is applied indiscriminately to all the linear markings and streaks, the general statement sometimes met with, that photography does not show the canals, is apt, if unqualified, to be misleading The 'canals' bounding Elysium, and those in the neighbourhood of Solis Lacus, as well as strong broad features, such as the Casius and Nepenthes-Thoth have been for several years past, do come out very plainly on the photographic plate Moreover, such features were seen and drawn before Schiaparelli's time, and, in general, so far from being straight, many of them are very distinctly curved Of the objective existence of these markings we may feel assured As in the case with the term 'mare' for the designation of lunar features, it may now be difficult, perhaps, to give up altogether the use of the term 'canal' for the linear markings of Mars, as M Antoniadi has done, but the retention of the same term for objects of widely different characteristics can scarcely be other than a fruitful source of misunderstanding and confusion

Another point which M Antoniadi's researches—and, indeed, the work of many other observers, like Prof W H Pickering, who has similarly devoted many years to the study of Mars and its seasonal changes—reveal with great clearness is that, despite its shortage of water, Mars is by no means as yet a dead world The work under review is not directly concerned with those recent methods of investigation by photography in light of different wave-lengths or the measurement of the surface temperature with the thermo-couple which have gone so far to establish points of analogy with the earth, but the visual revelations of the telescope described by M Antoniadi, such as the drift of the clouds and other manifestations of Martian meteorology, the seasonal changes in the colour, form, and intensity of dark markings like the Syrtis Major, the occasional developments and changes on an enormous scale like those observed in recent years in the Solis Lacus and Noachis regions of the disc, all indicate that Mars is still very much alive and full of interest for the student of its surface and physical state

At the end of the volume are a number of plates which are exceedingly well reproduced The first five are maps and these are followed by plates containing four whole-disc drawings of the planet as seen at Meudon during the apparitions of 1909, 1911, 1924, 1926, and 1928–29

Our Bookshelf.

L'art primitif Par Prof G-H Luquet (*Encyclopédie scientifique Bibliothèque d'anthropologie*) Pp iii+267 (Paris Gaston Doin et Cie, 1930) 30 *francs*

IN "L'art primitive" M Luquet turns once more to the problem of the origin of art Very briefly, his theory is that two forms of representative art are to be distinguished First, there is the classical art of the adult, no longer to be regarded as the one and only form Secondly, there is a form of art which is called 'primitive' Under this heading, on the ground of their common characteristics, he groups certain tendencies opposed to those of the adult classical art—the art of children, some adults ("même des professionnels"), savages, and prehistoric man Both in the individual and in the history of the human race, the urge to artistic representation arises in the same way—an accidental production or discovery of a resemblance to a real object Hence comes a desire for the execution of a purposive reproduction, which in turn gives rise to the pleasure of creation In this disinterested art lies the germ of magical art, but the pre existence of the artistic product before its magical use is a necessary postulate Further, while 'classical art' is static, primitive art is dynamic, by an intellectual realism it sees the whole story in time and space Hence the representation of invisible parts, distorted perspective, and duplication

M Luquet argues his case ably, with illustrations drawn from primitive art and from infant psychology The book is stimulating but far from conclusive Savages are not children, whatever may be the similarities in the artistic products of each Even if fortuitous resemblance gives rise to artistic activity in both cases, the savage brings a range of relatively highly developed concepts to bear upon his problem from the very first There is, in fact, no reason why the magical impulse should not be present from the very beginning The real analogy is not with the art of children, in which it is difficult to isolate the spontaneous activity from the imitative, but with such an urge as that for jewelry, in which an artistic product is the ultimate outcome of the magical efficacy of a natural object, afterwards imitated in some precious or magical material—for example, coral—and finally desired for its beauty or intrinsic value without reference to any original meaning

Some Applications of Organic Chemistry to Biology and Medicine By George Barger (The George Fisher Baker Non resident Lectureship in Chemistry at Cornell University, Vol 5) Pp v+186 (New York McGraw Hill Book Co, Inc, London McGraw-Hill Publishing Co, Ltd, 1930) 12*s* 6*d* net

THIS volume represents the fifth of a series in which are reproduced the lectures delivered by distinguished visitors invited to Cornell University in accordance with the terms of the George Fisher Baker Foundation The purpose of this Foundation is to facilitate intercourse between scientific

workers of different nationalities Appropriately, Prof Barger deals in his introductory lecture with the history of internationalism in science The belief that scientific research is one of the most international forms of human endeavour, possibly only second to music in this respect, is illustrated by a remarkable range of examples that connects the brotherhoods of the schools of Vesalius, Fabricius, and other great masters of the Italian universities of the sixteenth century with the international contributions that led to the isolation, identification, and synthesis of adrenaline Many other examples may be derived from the five lectures which follow and which deal with important recent developments in biochemistry The chemistry of the hormones is presented in an able and comprehensive review, no small part of which is devoted to the fascinating story of the steps by which the constitution and synthesis of thyroxin was achieved Other lectures deal with the chemistry of the vitamins, chemical constitution and physiological action, chemotherapy, and finally the nature of the curious blue adsorption compounds of iodine A very interesting and stimulating volume

Niels Henrik Abel eine Schilderung seines Lebens und seiner Arbeit Von C A Bjerknes Umgearbeitete und gekurzte Ausgabe aus Anlass von Abels 100 jahrigem Todestag von Prof Dr V Bjerknes Ins Deutsche übertragen von Else Wegener-Koppen Pp v+136+1 Tafel (Berlin Julius Springer, 1930) 6 60 gold marks

PROF V BJERKNES has condensed the longer work of his father by omitting the details of Abel's mathematical work, so as to make accessible to all the biography of that ill fated genius

Abel was born in 1802 His abilities were dormant until he met with a sympathetic teacher, who soon prophesied his future greatness However, a local reputation in a country like Norway required support from abroad In spite of his poverty, Abel had a paper printed at his own expense and sent a copy to Gauss, the acknowledged leader of mathematical thought, whose appreciation would have made Abel's position secure But the paper was poorly printed, with portions of the argument omitted, and Gauss tossed it aside Later, Abel was given a travelling scholarship, but his resentment prevented him from meeting the only man who could have fully understood his work In Berlin, Abel was welcomed by Crelle, who published in his newly founded *Journal* several of Abel's papers But a professorship in Christiania, which Abel had confidently expected, was awarded to another Fresh disappointments awaited him in Paris He sent to the Academy what is now known as Abel's theorem This should have assured his fame, but by some amazing mischance it was not printed until fifteen years later Long before this, Abel had returned home and for two years struggled with financial cares Then at last recognition came, and in 1829 he was offered a professorship in Berlin Too late! He had died two days before

H T H P

Clouds By Prof Alexander McAdie Pp iii+22 +52 plates (Readville, Mass Blue Hill Observatory)

MORE attention has probably been given to the study of clouds at Blue Hill Observatory, Massachusetts, than anywhere else in the world, and the appearance of a volume containing the cream of the many fine photographs of clouds taken there, in addition to a selection of photographs from other sources, is to be welcomed The reproduction of these varies According to the very high standard of the present day, many of the photographs of cirrus cloud can only be classed as poor, the essential fibrous structure being replaced by a wool-like appearance almost suggestive of fracto cumulus at a first glance Even the comparatively easily reproducible cumulus and cumulo-nimbus are not as a rule entirely satisfactory, a common fault being the total lack of detail in those parts of the cloud that are in shadow Against these drawbacks must be set the exceptionally interesting view point from which some of the low forms of cloud have been photographed, and the amount of light thrown upon their physical structure in consequence It will come as a revelation to those who have not had many opportunities of studying clouds from above, the extent to which fog sheets can form 'surges' and cascades when drifting over hills, without being broken up or dissolved

An important feature of the work is the historical sketch with which it opens We cannot recall having seen a more comprehensive guide to the most important attempts at a scientific treatment of the study of clouds, from the tentative observations and speculations of Socrates to the recent intensive study of cloud formations in relation to moving pressure systems made by the French National Meteorological Office Prof McAdie has done good service to meteorology by this piece of work

The Measurement of Men By J A Harris, C M Jackson, D G Paterson, R E Scammon Pp vii+215 (Minneapolis University of Minnesota Press, 1930) 2 50 dollars

FOUR lectures, delivered under the auspices of Sigma XI of the University of Minnesota, are here published as a contribution to the exact study of man by means of measurement Prof L Arthur Harris deals with "The Measurement of Mankind in the Mass", an exposition of statistical methods and some results, Prof Clarence M Jackson deals with "Normal and Abnormal Human Types", Prof Donald S Paterson with "Personality and Physique", and Dr Richard E Scammon with "The Measurement of the Body in Childhood" Prof Jackson gives some interesting comparative figures from the army and from university students which will probably be new to most English readers, while Prof Paterson makes some amusing and destructive comments, supported by statistics, on the distinction popularly drawn in the United States between the mentality of blondes and brunettes, and on the claims of physiognomy and phrenology to gauge character

Letters to the Editor.

Emergent Evolution

IT is curious that while the concepts of physics have been undergoing drastic revision, the same has not happened with regard to biology It is true, Dr E S Russell has recently examined very critically what is meant by organic development, but very much more is still necessary in respect of other conceptions of biological science Here I refer particularly to the notion of 'emergence' in evolution—by which, Dean Inge says, we assert and deny change in the same breath! The conception, as it has been stated so far, involves confusion, and it would be well worth while for someone familiar with the formal methodology of science to attempt a very critical discussion of the matter

The notion of emergence is illustrated by the formation of water from its elements There is nothing in the reactants, it is said, which suggests the liquidity of the resultant liquidity, therefore, is said to 'emerge' from the reaction of oxygen and hydrogen to form water But may we not regard these reactants as mass-points in a Newtonian medium, moving in accordance with Newton's laws, and attracting and repelling each other with forces which are functions of their distances apart We describe such a system of mass points by position- and force-co ordinates Since the mind body problem is the same in our perceptions of the properties of reactants and resultants, may it not be regarded as cancelling out, so that liquidity in the resultant *is* the changes of co ordinates? Of course, we may make an analogous statement with regard to an electronic medium

Again, the properties of the atom are said to 'emerge' from some configuration of the elements of the atom But that configuration, to J J Thomson, was not the configuration imagined by Rutherford and Bohr, and, again, not the configuration of current physics Yet the 'emergent' properties are still the same ones Finally, we can make systems of equations representing the thermodynamic probabilities of two or more gaseous systems and we can deduce from those equations that the entropy of a combined system is proportional to the logarithm of the combined probabilities May not the latter equation be said to 'emerge' from the former ones, and yet does it contain any terms that were not in the equations from which it was deduced? Is not what 'emerges' *a relation made in the mind of the investigator*? Were not the electronic configurations simply in the minds of mathematical physicists rather than in the atomic systems?

These examples are very simple ones what emergent evolution rather contemplates are the origins of human mentality, 'values', the religious feelings, and God Science now, in its modesty and self critical outlook, is being said to admit, or at least tolerate, speculations with which, in a more assertive (or truculent) phase, it would have nothing to do Has not the time come when notions such as that of 'emergence' and 'organicism' should be dispassionately and critically (or even unsympathetically) considered in the interest of sound thinking?

JAS JOHNSTONE

University, Liverpool

Embryology and Evolution

I SHOULD like to comment on two letters by Mr Haldane one on "Natural Selection Intensity as a Function of Mortality Rate", in NATURE of Dec 6, and the other on "Embryology and Evolution", in the issue of Dec 20 In the first, Mr Haldane criticises as "fallacious" Prof Salisbury's argument that mortality amongst plants is mainly confined to the seedling stage and that at this period natural selection mainly works He goes on to consider a case where two races vary as to a single character! Now, this is a travesty of what occurs in Nature Two allied races do not differ from one another in a single character they differ in a multitude of minute points, and it is quite impossible to say whether one or another of these points determines their survival The 'characters', in fact, are mere abstractions The organism is a whole, and the characters are the expression of its constitution, in a word, of the vigour of its reaction to its surroundings The whole point of Prof Salisbury's argument was that natural selection chooses the most vigorous, not that which possesses some special character, and this argument I believe to be perfectly sound

In his second letter Mr Haldane objects to four of the statements in my reply to Prof Gates I shall deal with these seriatim

(1) Mr Haldane claims that some microscopists have seen 'genes' What they have seen are segregations of material in the stained and fixed chromosomes which they have identified as genes—a purely hypothetical conclusion He further says that the presence or absence of a 'trabant', that is, not a gene but a small chromosome, makes a difference in the constitution of the plant *Matthiola* This is quite possible, and I shall be glad to have it demonstrated Prof Gates was I think, the first to show that an extra chromosome made a difference to the appearance of the mutant

(2) Mr Haldane asserts that scores of cases are known where in interspecific crosses characters behave in a Mendelian manner, that is, are due to genes All I know on this subject is that my friends who are systematists, and have devoted their lives to the study of species and races deny that such is the case Of course, a mutant such as the domesticated race almost always 'mendelises' when crossed with the wild type, that is just what distinguishes a mutant from a racial character, and the case quoted by Mr Haldane is such a cross

(3) Mr Haldane states that autocatalytic reactions are common in physical chemistry By this is meant reactions in aqueous solutions which are accelerated by the products of the reaction I put this question to three first class chemists, all of them fellows of the Royal Society and one of them a bio chemist, and as they were all unaware of any such case, I prefer to accept their testimony

(4) Mr Haldane objects to my posing the alternative of the organs being preformed in miniature in the embryo or being due to an 'unknown cause' He says that bone is formed by an enzyme 'phosphatase' This is a mere quibble Enzymes are *means* employed by the embryo to develop its powers, and their orderly appearance is just as much a mystery as the appearance of the organs themselves

Mr Haldane's remarks about my refusing to take cognisance of the recent advances of science and his invitation to acquaint myself with the 'facts' of genetics and chemistry I prefer to disregard I have quoted the authorities on whom I rely in chemical matters As to genetics, I have served for seventeen years on the Council of the Institution to which Mr

Haldane is attached as statistician, and I have watched all the work going on there, and the more I see of it the more I am convinced that Mendelism has nothing to do with evolution

E W MACBRIDE

43 Elm Park Gardens,
Chelsea, S W 10,
Dec 23, 1930

THE discussion between Prof R Ruggles Gates and Prof E W MacBride, in NATURE of Dec 6, bears in an important way upon the philosophy of science May one without authority in biology offer what he hopes may be a useful contribution from the philosophical point of view?

It is the function of the scientific man to discover facts, to endeavour to co ordinate them, and by generalisation to build up a useful scheme of hypo theses Such a scheme must be a deterministic scheme or it cannot be useful, that is, it cannot be used to forecast further facts When Prof MacBride writes of mechanical hypotheses, he refers, presumably, to such a deterministic scheme Whether the resulting scheme represents the truth is not the business of the scientific man as such, but of the philosopher

As a philosopher Prof Gates may believe himself to be a "mere mechanism" or a Drieschian entelechian organism For science this is beside the question A scientific man must continue to have faith in "so called mechanical hypotheses", or, as Prof Gates says, "there would be no further incentive to experimental embryology", and his function would cease As a philosopher he may doubt whether such deterministic schemes will ultimately prevail, but as a scientific man he must carry on

The General Factor in Spearman's Theory of Intelligence

SPEARMAN'S theory may be summarised as follows

(1) A mathematical theorem, that when all the tetrad differences such as $(r_{ab}r_{cd} - r_{ac}r_{bd})$ formed from N variables $a, b, c, d,$ vanish, each variable may be considered as the sum of two parts (or 'factors') which are numerical multiples of a general factor g (the same for every variable) and of a specific factor s (different in each case) These $N+1$ factors are all uncorrelated with each other

(2) The attribution principally to mere error of sampling of the non vanishing of the small tetrad differences formed from dissimilar mental measurements

(3) The interpretation of g as general mental energy, and of each s as a specific ability

Spearman's proof of (1) is given on p v of the appendix of his "Abilities of Man" (1927) The value of g (there called η) is given in the form of a complicated determinant involving a variable ι which is undefined except that it is "any new variable un correlated with all the others" No clue is given to show how the determinant was obtained The object of this letter is to point out a straightforward method by which an equivalent but much simpler expression can be obtained, and to show the nature of the mysterious variable ι, concluding with a very brief discussion of the psychological interpretation The error of sampling is too large a subject to consider here.

To obtain an expression for g, first suppose that the variables *can* be divided into general and specific factors, that is, suppose that

$$a = m_a g + n_a s_a,$$
$$b = m_b g + n_b s_b, \text{ and so on,}$$

where the m's and n's are constants, but g and the s's variables, no two of which are correlated (It is con venient to use *standard measure* for the variables this ensures that all the means are zero and all the standard deviations unity) We find that the tetrad differences all vanish and hence that $\{r_{bc}/(r_{ab}r_{ac})\}^{\frac{1}{2}}$ has a value depending on a alone, so that it may be denoted by μ_a Now choose multipliers $w_a, w_b,$ such that the correlation between g and the combined test $t = \mathrm{S}w_a a$ may be a maximum This gives $w_a = \mu_a/(\mu_a^2 - 1)$ Then form an estimate of g in the usual statistical way (assuming *linear* regression) by using a regression equation $g = r_{tg}\sigma_g t/\sigma_t$ This, of course, will not give the exact value of g Call the unavoidable error $k\iota$, where ι is a variable and k a constant chosen to make the standard deviation of ι unity This leads to the expressions

$$g = k^2[\mathrm{S}\{a\mu_a/(\mu_a^2 - 1)\} + \iota/k]$$

and $$s_a = (\mu_a^2 - 1)^{-\frac{1}{2}}[a\mu_a - k^2\mathrm{S}\{a\mu_a/(\mu_a^2 - 1)\} - \iota k],$$

where $k^{-2} = 1 + \mathrm{S}\{1/(\mu_a^2 - 1)\}$

It is easily verified that ι is uncorrelated with each of $a, b, c, d,$

Conversely, whenever the tetrad differences all vanish and in consequence the μ's exist, it is only simple algebra to verify that $a = g/\mu_a + (s_a/\mu_a)(\mu_a^2 - 1)^{\frac{1}{2}}$, with similar expressions for the other variables, and on calculating the coefficient of correlation between any two of $g, s_a, s_b,$ we obtain zero, provided ι is uncorrelated with $a, b,$ In this *converse* work there is no need to assume linearity of regression, which is needed only if we wish to deduce *independence* from zero correlation There is also no appeal to Taylor's theorem For g to be real the coefficients of correlation between $a, b, c, d,$ must all be positive

An interesting example, in which at first sight there appears to be no general factor, is the following

$$\begin{aligned} a &= \tfrac{1}{2}(\phantom{u+{}} v + w + t + p), \\ b &= \tfrac{1}{2}(u \phantom{{}+v} + w + t + q), \\ c &= \tfrac{1}{2}(u + v \phantom{{}+w} + t + r), \\ d &= \tfrac{1}{2}(u + v + w \phantom{{}+t} + s), \end{aligned}$$

where each variable on the right hand side represents the score (reduced to standard measure) of a die We find $r_{ab} = r_{ac} = \quad = \frac{1}{2}$, and so each $\mu = \sqrt{2}$ This gives

$$g = \frac{1}{5\sqrt{2}}\{3(u + v + w + t) + (p + q + r + s) + \iota\sqrt{10}\},$$

and

$$s_a = \frac{1}{5\sqrt{2}}\{-3u + 2(v + w + t) + 4p - (q + r + s) - \iota\sqrt{10}\},$$

so we have resolved the overlapping group factors into the general factor which seemed to be lacking

Some may consider that the occurrence of the chance or uncertainty factor ι in the above result robs it of all real value But if the two factor theory is true, the uncertainty cannot be avoided, for from N equations we cannot determine the $(N+1)$ unknowns (one g and N s's) Moreover, by increasing N the coefficient of the uncertainty term can be made as small as we please However, it may be conceded that to a person who knew nothing about dice, the above expression for the general factor might convey a wrong impression, and to guard against a wrong interpretation of mental tests it is necessary to acquire some knowledge of them apart from the mathematical results It is at once the strength and the weakness of mathematical reasoning that it is generally adaptable to more than one set of circumstances Let psychologists find two individuals who do equally

well at a mental test, but such that one has a large g and small s, the other a large s and small g, and consider whether there is sufficiently good correspondence of these variables with what on other grounds may be considered general mental energy and specific ability Other results, such as the difficulty in transfer of training, may be of service

Further deductions from the above expressions for g and s are being investigated I have been greatly helped by my colleagues, Miss A E M M Dallas and Mr M M Lewis

H T H PIAGGIO

University College, Nottingham,
Nov 22

I QUITE agree that Prof Piaggio's proof is not only much simpler than that given in "The Abilities of Man", but also more illuminating I agree with Prof Piaggio generally, subject to the reservation that I do not consider (3), the interpretation of g as general mental energy, to be any essential part of the theory Essential for me is that the determination of g and s leads on to that of 'group' factors, and then the varying magnitude of all three kinds of factors under varying conditions connect them up with all the laws of the human mind, as also with such influences as age, heredity, instruction Thereby, I believe, psychology is placed upon a new basis, in which the old but still prevalent 'faculties' are replaced by statistically established unitary functions I suggest that all these positive observations are at present being side tracked by undue prominence given to such speculative (however luminous) hypotheses as that of a 'general energy'

C SPEARMAN

Administration and Anthropology in India

MR CODRINGTON is unaware of the facts that in this University lectures are given every year to I C S probationers on the ethnology of India, and that an Indian area is selected for special study in the Tripos The work done by Dr Hutton and by Mr Mills is evidence that fieldwork is existent in India Nevertheless I share Mr Codrington's regret that though the facts are accessible enough to those who have cared to work them over, the present discussions at the Conference are not enhanced by anthropology

T C HODSON
(Reader in Ethnology)

University Museum of Archæology
and of Ethnology,
Downing Street, Cambridge,
Dec 15

THREE of Mr Hodson's criticisms I can answer very shortly

(1) I am well aware of the existence of the I C S probationers' courses I have expressed the opinion that considering the importance of anthropology to the embryo administrator, they are scarcely sufficient

(2) The option of selecting an Indian area in the Cambridge Anthropological Tripos is something However, I have pointed out that the district gazetteers, which must be the source books for this work, are "uncorrelated compilations", in my opinion, they are extremely difficult to handle critically, without some personal knowledge of the areas concerned

(3) With regard to my alleged neglect of Dr Hutton's and Mr Mills's magnificent work, I can only point out that I was discussing the impending carving up of India into federated units the Assamese hills are not culturally part of India proper, and from the point of view of the problem under discussion, they offer no great difficulty, because their cultural boundaries are clearly defined

The only remark of Mr Hodson's that I feel called on to reply to in detail is his assertion that "the facts [of Indian anthropology, that is, as bearing upon the creation of a federal India] are accessible enough to those who have cared to work them over". If this is so, why is there no generally accepted handbook of Indian ethnology ? Why is there no volume covering the field of India folk lore ? Why is it that no work has been done on Indian technology since the pioneer publications of Birdwood and Watt, nearly thirty years ago ? How is it that the 1 in sheets of the Survey of India are unpublished for large and important ethnic areas in India, although they are absolutely necessary for research of any kind in those areas ? Why is it that until very recently one so seldom heard Indian research matters discussed at academic gatherings ? Why is it that there are still so few specialists in Indian cultural studies ? Why is the flow of publication so sluggish ? The answer can only be that the basic data, physical and cultural, have never been provided in the necessary quantity over the necessary range, and that in default of critically conceived local studies in which the environment is taken into consideration, we have no means of manipulating the impressively massive, but uncorrelated, facts of our source books—the gazetteers

In checking the accessible literature, after any discussion of points of interest, with local observers fresh from India, one is forced to acknowledge gaps and discrepancies on all sides, and furthermore a wellnigh hopeless confusion of nomenclature The present system of recording the castes and tribes of India, upon which the monumental Census Reports, perhaps the finest of their kind in the world, are based, is an artificial system in the botanical sense Such groups of people as the Khorwa, Kapu, Vellala, Megh, and such a group as the Kurumban-Kuruba-Kurma complex which are all paraded as ethnic units in the Census Reports, are not proved entities in any scientific sense Few, if any, of them have been studied as they actually exist, in their villages and families none have been studied, even generally, over the whole of their very large areas of distribution In other words, the units have never been defined in their own environment, and we are therefore ignorant of the degree of homogeneity or variation of the alleged class

For example, there are two great castes of glass workers, nowadays mainly occupied in the manufacture of glass bangles, the Manihar and the Kachera The former have a distribution running through the Punjab, Rajputana, and the United Provinces the latter, who are much fewer in number, are confined mainly to Central India What is the real relationship, ethnical and historical, between these two professional groups, and what bearing has their modern craft upon the enormous glass bead manufacture of South India in Pallava times, of which we have just become aware ? It will be seen that this problem is the reverse of the former In many cases it is certain that unrelated groups have been lumped together under one caste title It is as certain in other cases that the same people have acquired two or more official caste names, because their distribution area straddles one or more official, political boundaries with opposing, official machinery on either side The Beda [Bedaru], Berad [Bedar] and Boya are all differentiated in the Census Reports and gazetteers, as "castes" or "tribes", but they are actually the remnants of a widely spread *nation*, numbering almost a million and a half souls, if the kindred Ramoshis of the Bombay hills and Vedars of the South are taken into consideration They are at present politically administered, as

inhabitants of various districts of the Madras and Bombay Presidencies, and of the Mysore and Hyderabad States How is this block of ethnic and traditional interests to be treated on the proposed dissection of India? By modern standards the extant literature, a few dozen scattered pages, is totally inadequate, considering the gravity of the point at issue Here are a few of the problems which I had in mind when I said that sufficient facts were not accessible to split a population of such ethnic and traditional complexity into federated units with anything approaching scientific assurance

To any Englishman the necessity of such a confession must be a bitter thing The political issue is upon us—but we may still hope for the scientific issue It is still possible to set to work, and so fill a glaring hiatus in anthropological knowledge What is urgently wanted is a series of local surveys based on lines of centres drawn along and across the most obvious cultural borders such a line as Junnar, Paithan, Ellora, Ajanta, Akot Each centre would have to be treated as a living organism, attention being paid equally to the anthropometry, sociology, verbal traditions, local cults and antiquities, the survey extending perhaps ten miles or a morning's ride from each centre As the investigation proceeds, errors in caste terminology will cancel themselves out The task is a straightforward one of simple recording, which must, however, be based on a strictly standardised technique Fortunately there is some possibility of such work being done in the near future by a party of English and Indian scholars working over a number of such groups of centres

I apologise for occupying so much space with this statement, but the situation is serious My letter was intended to express my appreciation of the leading article on "Administration and Research in India" in NATURE of Nov 22 I had no desire for controversy and I regret that I must differ from such an authority as Mr Hodson A confession of ignorance in the matter of Indian cultural studies is necessary at the moment, in order to create the possibility of regeneration The first step must be academic recognition, in the form of a chair or lectureship

K DE B CODRINGTON
Claire Cottage, North Road,
London, N 6

The Function of the Air Sacs of Insects

THIN WALLED expansions of the tracheæ known as air sacs occur in those insects which have well developed powers of flight Misconception as to the function of these structures is common They have been described as pumps, as reservoirs, and as balloons The first term alone seems to give an accurate description of their function, for Lee has made it clear that they must ventilate the tracheæ each air sac, when compressed, expels the air from the trachea between it and the spiracle As reservoirs the sacs could be of little use to aerial insects, for the oxygen they contain would last but a very short time during flight, while there is an unlimited supply of air only a little farther from the tissues [1,2]

The common belief that air sacs could act in the same way as the balloon or gas bag of an airship is equally untenable Packard[3] says "It is evident that the enormous powers of flight possessed by the locust, especially its faculty of sailing for many hours in the air, is due to the presence of the air sacs, *which float it up on the atmospheric sea* It will be seen that, once having taken to flight, the locust can buoy *itself* up in the air, constantly filling and refilling its internal buoys or balloons without any muscular exertion, and thus being borne along by favorable winds to its destination" Deegener[4] considers such a function possible when he says " es [das Tier] verdrängt mehr Luft und wird spezifisch leichter Ob sie [Verringerung des spezifischen Gewichtes] weit genug geht, um eine befriedigende Erklärung fur die Existenz der Luftsäcke zu geben, lässt sich somit nicht entscheiden" (See also Comstock[5]) It is not difficult to show that this decrease in specific gravity does *not* provide an explanation for their existence, and that they could not possibly buoy up the insect sensibly

Consider such an insect as the bee, and for convenience include all tracheæ capable of varying in capacity under the title of air sacs Let—

Weight of insect *in vacuo*	$= W$
Weight of insect in air	$= W_a$
Volume of insect, with sacs deflated	$= V$
Volume of expanded air sacs	$= v_a$
Volume of remainder of tracheal system	$= v_t$
Density of external air (gm per c c)	$= d$
Density of air in tracheal system	$= d_t$

According to the Principle of Archimedes, the upthrust of the air on the insect is equal to the weight of air it displaces, therefore, the weight in air of this insect with air sacs expanded is

$$W_a = W + (v_t + v_a)d_t - (V + v_a)d \qquad (1)$$

The weight of air in the tracheal system—$(v_t + v_a)d_t$—must be included in the weight of the insect, especially since it is this very air which is supposed to buoy the insect up

Suppose that the air in the tracheal system is at the same temperature and pressure as the external air, that is, $d = d_t$ When the insect has its air sacs expanded

$$\begin{aligned} W_a &= W + (v_t + v_a)d - (V + v_a)d \\ &= W + v_t d + v_a d - Vd - v_a d \\ &= W + v_t d - Vd \end{aligned} \qquad (2)$$

When the air sacs are collapsed ($v_a = 0$), (1) becomes

$$W_a = W + v_t d - Vd \qquad (3)$$

That is to say, the weights in air in the two cases are exactly the same Obviously, the weight of the air in the sacs is exactly equal to the additional upthrust due to its presence there

Suppose that the air in the tracheal system has a lower density than the external air and take the extreme case when there is a vacuum in the uncollapsed system, that is, $d_t = 0$ Then (1) becomes

$$W_a = W - (V + v_a)d \qquad (4)$$

Suppose that $v_a = V$, that is, that the volume of the insect is doubled by the expansion of the sacs—an exaggerated case Then (4) becomes

$$W_a = W - 2Vd \qquad (5)$$

If the density of the insect *in vacuo* is 0 5 gm wt per c c and of the air 0 0012 gm wt per c c, the lift of these most remarkable sacs (Vd) would be about one four hundredth part of the weight of the insect, comparable to half a pound in a man weighing fourteen stone Actually the density of the air inside the animal cannot be very different from that of the external air, and in any case it is to be expected that the pressure in the tracheæ is sometimes above and sometimes below atmospheric pressure, so that any buoyancy effect is minute indeed

The fact that the *density* of the whole insect would be reduced by the addition of air sacs does not affect the *weight* in air at all If the insect were made as big as a house by the addition of weightless air sacs filled with air of atmospheric density, the same force would still be required to lift it, though its density would be enormously reduced An

insect of this remarkable design would offer a very large surface to the winds, and wind forces would be very large compared with its weight and with the forces it could itself exert, and it would blow about like thistledown But the insects which possess air sacs are just those which rise superior to these external forces, the swift and the strong flying ones To them any increase in surface area is a disadvantage only to be borne if there is some greater advantage accompanying it This advantage, I suggest, is the increased rate at which oxygen can reach the tissues when tracheal ventilation is aided by air sacs

Mirage at Cape Wrath on Dec 5, 1922

THE compiler of the Calendar of Historic Natural Events is to be congratulated on the success of his enterprise All the notes are interesting and many invite discussion It is to be hoped that they will be republished in book form with references to the original authorities

The note on the mirage seen at Cape Wrath on Dec 5, 1922 (NATURE, Nov 29, p 865), is, I suggest, one of those which will require reconsideration before it is republished In considering an observation of mirage, it is necessary to distinguish three elements what the observer saw, what the observer thought he saw, and how his observation is to be explained In this instance (NATURE, Feb 17, 1923, p 222) the lighthouse keeper at Cape Wrath was looking land wards through a telescope and observed that " a belt of the atmosphere appeared to be land and sea " It seemed to him that what he saw was a perfect representation of the whole of the coast line from Cape Wrath to Dunnet Head, " an exact replica of what would have been seen from a distance of 10 miles out at sea " It is admitted, however, that " Cape Wrath itself was rather indistinct " Bays were noticed, but nothing characteristic, like a lighthouse, is mentioned

All that is clear is that the observer saw in the sky a strip of variable width which suggested land to him, and that below this strip there was an appearance which could be taken for the sea

Now, it should be remembered that it is often exceedingly difficult to discriminate between the distant sea and the sky I have had many opportunities for observing inferior mirage at sea One sees a distant rock and its image as a single symmetrical object and sometimes it is very difficult to get rid of the im pression that the sea surface is visible right up to this object, even though one is convinced that reflection is being produced by warm air The illusion is closely akin to the illusion of water in the desert

Superior mirage is not so frequently observed, but it is to be expected that it will also be accompanied sometimes by the illusion of water where there is no water The phenomenon observed from Cape Wrath was, I believe, a case of superior mirage The reflec tion of distant hills might well have an irregular outline reminiscent of capes and bays

From the meteorological point of view this hypothesis presents no difficulty Superior mirage is ex plained as due to the total reflection of light, or rather the continuous refraction of light, at an inversion of temperature, warm air lying above cold in horizontal layers Inversions are by no means uncommon phenomena

I hope that its author will forgive me for saying that the original explanation of the Cape Wrath mirage as due to repeated reflection, light being reflected twice at vertical surfaces of separation between hot and cold air, is, to my mind, quite untenable In every observation of mirage, the angles which the incident beams of light make with the reflecting layer are very small When reflection is from air, direct reflection, such as occurs when an observer looks at the image of his own back in a pair of mirrors, is out of the question As, however, columns of hot air and cold air with a vertical boundary could not persist for a minute, there seems to be no possibility of actually testing the reflecting power of such a combination The Cape Wrath phenomenon loses in interest by being docketed in the familiar category ' superior mirage ', but that is, I fear, inevitable

Saxifrage Crosses

R O WHYTE[1] makes the statement (repeated under Research Items in NATURE of Nov 1, 1930, p 702) that the hybrid *Saxifraga potternensis* arose by doubling of the chromosomes at the semihetero typic division of the F_1 between *S rosacea* and *S granulata*

Doubling of the chromosome number may occur either during the somatic divisions or by failure of reduction These two methods have definite characteristics differentiating them in respect to seed production If the doubling takes place during mitosis, the seed production of that portion which is ' tetraploid ' will be equal to or greater than that of the derivative and following generations On the other hand, if the doubling takes place through failure of reduction, the number of seeds produced with the doubled chromosome number is a function of the number of unreduced germ cells The proportion of these is necessarily small, and they are distributed irregularly over the diploid parent plant Consequently the amount of seed produced per plant is much reduced as compared with that of the tetraploid offspring On the other hand somatic doubling gives full fertility in the *one part* affected

The following table of the seed production of the

	Seed Production of F_1 Plant	Seed Production of derivative Generations (for comparison)
DOUBLING BY FAILURE OF REDUCTION		
Raphanus Brassica[2]	45 per plant	30 per pod
Phleum pratense × *P alpinum*[3]	46 in 5 hundred thousand flowers 4 germinated	Over 400 per plant 90% germination
Digitalis purpurea × *D ambigua*[4]	200 seedlings from 2 plants	400 per capsule
DOUBLING IN THE SOMATIC TISSUES		
Nicotiana glutinosa *N tabacum*[5]	155 per fruit	?
Primula kewensis[6]	30, 90, 180 per fruit 287 germinated	122 plants per fruit
Solanum Lycopersicum[7]	20 per fruit 10 germinated	20 per fruit
Saxifraga rosacea × *S granulata*[1]	422 per fruit	85 per plant (average of 6 plants)

F_1 plant and of the derivative ' tetraploid ' generations illustrates the above fact, and indicates that *S potternensis* probably arose from an F_1 plant which

had a tetraploid number of chromosomes in a portion at least of its somatic tissue, and that it did not, as reported, arise from a semiheterotypic division of the F_1 hybrid Doubling of chromosomes in the somatic tissue is of rarer occurrence than the origin of tetraploids by failure of reduction, and *S potternensis* is an important addition to the small list of such somatically doubled forms F W SANSOME

Curling

WE have been interested in seeing the results of Prof Harrington's experiments on the motion of a curling stone on ice, published in the *Transactions of the Royal Society of Canada*, and referred to in his letter in NATURE of Sept 6, p 351, which show a considerable increase in the friction for small velocities This must produce, towards the end of a run, a couple tending to increase the spin of the stone, and no doubt explains the fact that the velocity of rotation remains nearly constant until very near the end But it has little or no bearing on what we have regarded as our main problem (see NATURE of Mar 15, 1930, p 408), namely, the production of the curvature of the path of a stone, at a time when the instantaneous centre of the motion may be at a distance of 2 feet or more from the centre of the stone, a considerable distance compared with the radius of the cup

Any difference of friction at the two sides of the stone, due to difference of velocity, must then be small But for our purpose it is not necessary to consider the magnitude of it, because it has no tendency to produce the curvature To account for the observed curvature of the path of the centre of a stone, we must find a force of sufficient magnitude in the direction of the normal to the path Resolution of the forces shows that a difference of friction at the two sides, if this is the only asymmetry apart from the spin, contributes nothing towards the production of the required force

We think that the final twist of a stone about a point of the cup, which occasionally occurs as the stone is coming to rest, may be due to regelation This satisfies the requirement of being a thing which may happen, but usually just fails to happen

The False Killer Dolphin

ACCORDING to a note in NATURE (Dec. 6, 1930, p 892), recording the stranding of a false killer dolphin (*Pseudorca crassidens*) in Ceylon in 1929, this species is "regarded as on the verge of extinction" The same statement has appeared elsewhere, but I venture to inquire whether there is any evidence that it is correct

The false killer was originally described, as *Phocæna crassidens*, by Owen, in 1846, as the result of the examination of a skull and other bones which had been found, sub-fossil, in the Lincolnshire Fens. In 1861 a school of about a hundred individuals appeared in the Bay of Kiel In 1862 specimens, probably belonging to the same school, were stranded on the Danish islands, and were investigated by Reinhardt, who established the genus *Pseudorca* for this species About two years later a considerable number of false killers were recorded from Tasmania Skulls from this herd were sent by Mr W L Crowther, in 1864, to the Royal College of Surgeons, and other specimens were sent by the same donor to the British Museum and the University Museum of Zoology at Cambridge The species has more recently been recorded from many distant localities, including Travancore, Florida, Argentina, Lower California, and Peru In 1906 several hundred individuals were stranded in the Chatham Islands The Dornoch Firth school, October 1927, is referred to in the note published in NATURE, as well as the large herd which was stranded near Cape Town in December 1928

Most of the earlier records of the false killer as a recent species are given by Dr J R Garrood (*Proc Zool Soc*, p 177, 1924), who described the very interesting discovery of two skeletons in the Cambridgeshire Fens in 1921

Justification for the belief that *Pseudorca crassidens* is on the verge of extinction seems to be very slight, in view of the above facts Mr W R B Oliver's statement (*Proc Zool Soc*, p 577, 1922) that this dolphin "is met with in large schools in New Zealand and Tasmanian waters" is in favour of this conclusion May it not fairly be supposed that the false killer, like many other dolphins, is an inhabitant of the open sea, and that its apparent rarity is merely due to the fact that it is not often observed in the neighbourhood of the land ?

Foaming of Beer

PERHAPS some light may be thrown on the phenomena referred to by Dr H S Rowell in his letters in NATURE of Sept 20 and Dec 13, by investigations carried out by B Shen, George King, and myself a number of years ago (*J Chem Soc*, p 1313, 1911, p 1170, 1913)

While the stability of the foam will depend mainly on surface tension and viscosity, the size of 'head' formed under the ordinary conditions of pouring out a glass of beer will depend mainly on the rate of evolution of carbon dioxide from its supersaturated solution in the beer This rate of evolution varies with the degree of supersaturation, which, in turn, depends on the nature of the beer and the method of its manufacture A pale ale, for example, was found to evolve carbon dioxide more rapidly than a stout or export beer The rate of evolution, moreover, depends greatly on the walls of the containing vessel and their effectiveness in supplying gas 'nuclei' to start the evolution of carbon dioxide

Traces of grease on the surface of the glass are very effective in promoting the escape of gas, and I think that the difference in 'head' obtained with a dry and wet glass is probably due to this fact Traces of grease are scarcely likely to be wanting from the surface of glasses dried under refreshment-room conditions In the case of a wet glass, there will be an absence of air bubbles on the surface to act as nuclei One cannot claim that the factors mentioned are adequate to account for all the phenomena, but they are probably the main factors involved

Entomology and the British Empire.

THE meeting of the Third Imperial Entomological Conference, which took place in London on June 17-27 last, has been regarded as a suitable occasion for a kind of stock-taking of what is being done towards combating insect losses in the British Empire. The Imperial Bureau (now Institute) of Entomology has done a useful service in bringing together data on this subject in an accessible and convenient form.[1] The criterion adopted is the amount of annual expenditure devoted to salaries, research, and general administration in each part of the Empire. While this method of treatment is an admirable one in many respects, it is obvious that expenditure respecting entomology incurred in one part of the Empire may not be strictly comparable with that incurred in another part: local needs, revenue, costs of living, and other factors vary so much in these respects. Due allowance needs, therefore, to be taken into account as regards differences of this nature.

When the losses due to insect depredations in the British Empire are represented in man power, we arrive at some striking conclusions. If it be admitted that 10 per cent is a conservative figure at which losses due to agricultural pests alone may be placed, it would seem that one tenth of the human effort on such a basic industry is dissipated by insect enemies. Taking the population of the Empire at about 450 millions, it may be assumed that an additional population of 45,000,000 could (if it were possible to eliminate insect pests) be supported by the same effort as that now exerted. It is estimated that in the Indian Empire, for example, the losses in 1921 due to crop and forest pests alone reached the huge total of £136,000,000, while the death-roll among the population due to insect borne diseases was stated to be about 1,600,000 persons annually. In Canada about £30,000,000 is lost every year through insect depredations among field and fruit crops and to forests. In South Africa one pest, the maize stalk borer (*Busseola fusca*), incurred losses of about £2,750,000 in a single year. Figures of this kind are, naturally, only estimates, but they serve to drive home how great these losses are. The losses to human communities by death or ill health arising from insect-borne agents of disease are most likely even greater than those occasioned to agriculture, but it would be exceedingly difficult to assess them.

A comparison of the effort made by the British Empire in coping with its entomological problems and that made by the United States is of considerable interest. The British Empire, with an estimated revenue of £1,400,000,000, devotes, in round figures, some £570,000 annually to work of this character, or 0.03 per cent of its income. There are fewer than three hundred[2] professional entomologists employed among a population which greatly exceeds 400,000,000 souls. The United States, with a population of about 106,000,000, spends an approximate sum of £2,000,000 (State and Federal allocations) annually, which works out at 0.25 per cent of its revenue of £800,000,000. It employs, moreover, not less than five hundred entomologists. The question is raised as to whether the British Empire can be justly claimed to be bearing its share in the world problems of insect control. On the basis of the United States' expenditure, that of the British Empire should be nearly six times as much as it actually is. Although insect problems in the United States are on a vast scale, they are more restricted in variety, and that country is faced with no responsibility so great as the tsetse fly problem in Africa and its immense toll of human life. The responsibility of an Empire so scattered, and concerned with so great a range of crops, peoples, and pests, would, therefore, appear to be a heavier one than that shouldered by the United States.

The varied responsibilities of the Imperial Bureau of Entomology have led to its outgrowing the original conception with which it was founded in 1913. Its recent change of title to that of "Imperial Institute of Entomology" indicates more adequately the scope of its activity and influence. The growth of its manifold activities are briefly dealt with in the Report of the Third Imperial Entomological Conference.[3] In recent years, for example, insects have been coming in at the rate of more than 5000 a month, and during the past five years very nearly 34,000 specific identifications have been issued. Despite the valuable aid given in this field by the staff of the British Museum, thousands of specimens are in hand which cannot yet be dealt with. There is urgent need for a competent dipterist on the staff: abstracting work is increasing beyond the means available and an additional preparator is required to cope with the influx of material. The rapidly increasing demands made upon the new Parasite Laboratory at Farnham Royal involve a further responsibility.

The higher salaries attached to official entomological appointments in many parts of the British Empire—but by no means all—compare favourably with those of other specialists in kindred posts. A perusal of the brochure[1] before us shows that there are two entomological posts of £2000 per annum or above; eight posts attaining a maximum salary of £1500 or above, but less than £2000 per annum; twenty-nine posts the emoluments of which attain £1000 per annum or above, but are less than £1500 per annum, and twenty six posts the maximum salaries of which range between £900 and £984 per annum.* On the headquarters staff of the Imperial Institute of Entomology, for example, there are three posts exceeding £1000 per annum, one post of £1000 per annum, and four posts rising to a maximum of £950 per annum. The salaries of entomologists attached to the Advisory and Research Services of the English Ministry of Agriculture, on the other hand, are on a markedly inferior scale. There are, at present, only three entomologists in the highest grade of the services, and their maximum salaries are attained at £830 per annum (which sum is consolidated and does not carry cost of living

* These figures do not include posts at the British Museum (Nat. Hist.) or at any English university or kindred institution.

bonus) This disparity seems even more striking when it is pointed out that the estimated mean loss by one single species of insect—the frit fly—amounts to nearly 15,000,000 bushels of oats per annum in England

At the present time, the British Empire lacks a sufficiency of young, properly trained entomologists of the right type The causes of this shortage are various, and, among them, the number of new posts established in recent years has been an important factor If developments are to progress at the same rate as hitherto, the matter of recruitment seems likely to become a problem of increasing difficulty

Cancer Research.

SEVERAL of the papers in the Ninth Scientific Report on the Investigations of the Imperial Cancer Research Fund (London Taylor and Francis, 1930 20s) deal with the fowl tumours which can be transmitted from bird to bird by tumour extracts filtered through filters so fine that the infective filtrate contains nothing large enough to be clearly visible under the highest powers of the microscope The nature of this 'agent' is the most crucial question of current theoretical cancer research It may, on one hand, be analogous to the invisible viruses which are associated with so many infectious diseases in animals and plants, it may, on the other hand, be a special example of the chemical substances arising from the disintegration or injury of cells which promote tissue growth The 'agent' by which transmission is effected may, in short, arise in the cancer cell or may come into the body from outside

The solution of this problem is, too, of more general importance, for the answer, whichever it is, cannot fail to influence our opinions as to the essential nature of the infectious viruses and the bacteriophage So far, these 'filterable' tumours are known only in birds Dr J A Murray and Dr A M Begg give careful descriptions of two, one is judged to be an endothelioma, the other is a slow growing fibro sarcoma Both appear to be quite different structurally from the well known Rous tumour, though it does not seem to be quite impossible that all are phases of the same kind of tumour Dr W Cramer has reinvestigated the possibility of transmitting rat and mouse tumours by tissue which had been repeatedly frozen and thawed, and in which all the cells were presumably and, so far as could be ascertained by tissue cultures, actually dead With carcinoma the inoculations were uniformly negative, some of the sarcoma preparations gave rise to fresh tumours and rapidly lost their infectivity on incubation or washing In another paper Dr Cramer and Mr H G Crabtree point out that positive results are not always obtained with frozen preparations of the Rous tumour, which is generally regarded as the typical filterable bird tumour The results, therefore, do not show conclusively that mammalian tumours can be transmitted from one animal to another without the intervention of living cells, but they certainly suggest that from some such tumours evidence may be obtained of a labile 'agent' similar to the 'agent' of the bird tumours

Three other papers, by Mr H G Crabtree, follow out the work of Warburg on tissue respiration The most interesting discovery is that the epithelial overgrowths of fowl-pox and vaccinia have an active metabolism of the type which has been supposed to be characteristic of malignant tumours This makes it more unlikely even than before that any alteration in cellular metabolism can be the cause of cancer

Dr R J Ludford discusses critically another theory of the origin of cancer, which supposes that malignancy may be due to chromosomal mutations in somatic cells—an idea specially associated with Boveri It is truly a remarkable fact that tumours practically always breed true that is, though a tumour may have little structural resemblance to the tissue from which it arises, it maintains a characteristic structure of its own throughout its history, which with some animal tumours is now a very long one, involving large numbers of animals It is also true that various irregularities in mitosis and in the chromosomes are found in malignant tumours But beyond these two facts there is really nothing to indicate somatic mutations as the basis of malignancy, and it is difficult to see how more conclusive evidence could be obtained

It is the fundamental property of malignant tumours that they are functionally isolated from the rest of the body and take no part in the coordinated activities of its various organs and tissues they live for themselves alone Hence they would not be expected to have either blood vessels or nerves of their own It has been stated from time to time that this generalisation is not universally applicable, and that nerves, for example, are sometimes present Dr Ludford has carefully worked over the matter in a number of mouse tumours and cannot assure himself that tumours cells are ever innervated the nerves sometimes found in the substance of tumours have probably been accidentally incorporated in the new growth in the course of its invasion of normal tissue

Dr J A Murray and Dr L Foulds have examined in various ways the proposition that the development of one tumour in an animal tends to inhibit the appearance of another, and Dr Cramer discusses another aspect of the same problem There is no doubt some immunity, partly general and partly local, but attempts to define the facts more precisely appear to meet with the most embarrassing vagaries of experimental results There must be some key point in the matter which has not yet been identified

Obituary

THE RIGHT HON LORD MELCHETT, P C, F R S

ALFRED MORITZ MOND was born on Oct 23, 1868, at Farnworth, in Lancashire, within smell of the famous alkali works His father, Dr Ludwig Mond, was at that time a chemist at the Hutchinson Alkali Works, it was not until five years later that he founded the firm of Brunner Mond in partnership with John Brunner, an accountant at Hutchinson's Mrs Ludwig Mond has described to me the Farnworth days as very happy ones--they preceded some very strenuous times at Winnington

Alfred Mond in his lifetime had thus seen the founding of the B M Works, as it is familiarly called in the north of England, the overcoming by strenuous effort of its early difficulties, both technical and financial, its growth to become the most important chemical firm in Britain, and its disappearance as an entity on absorption into Imperial Chemical Industries, Ltd Although he was associated closely with the management of the firm in early days, after the retirement to London and death of Ludwig Mond the active management at Winnington passed into the hands of Sir John Brunner and his two sons, and Alfred Mond's energies were largely spent in other directions

Educated at Cheltenham and the Universities of Cambridge and Edinburgh, he was called to the Bar via the Inner Temple and practised for a time on the North Wales and Cheshire Circuit before entering the family business at Winnington Ludwig Mond had interested himself in two other chemical ventures, one a process of refining nickel by means of the carbonyl it forms with carbon monoxide, and the other the well known Mond gas producer Both required skilled handling to carry them to practical and commercial success, and as the Brunners stood aside from them, this work fell on Alfred and his brother Robert and cousin Emil

By 1906 Alfred Mond found time to enter politics, and was elected for Chester as Liberal member in that year For some years politics more and more engaged his attention, and it was not until about 1925 that he seriously returned to the chemical industry, becoming chairman of Brunner Mond at a moment of internal crisis and throwing himself in characteristic manner whole-heartedly into its management Imbued with an intimate knowledge of world conditions and grasping the totally different state of affairs which the War had brought about in industry both at home and abroad, he set himself to bring about what is now known as rationalisation in the businesses in which he had authority The three great combines, Imperial Chemical Industries, Amalgamated Anthracite Collieries, and International Nickel, have resulted from his efforts, and their bigness and the courage displayed in their creation have made Mond's name known throughout the world All are too young as yet to have proved the wisdom of such rationalisation, but at least it is known to the scientific world that Alfred Mond's leadership involved recognition of the value and the utility of science in industry to an extent hitherto quite unknown in Great Britain

Imperial Chemical Industries from the first has set out to foster and encourage the development of schools of research at the universities, so that I C I might always find an adequate supply of highly-trained chemists available, it has bettered the conditions of employment of chemists at its works and brought into being at its individual factories research staffs of a magnitude and a capacity equal to that of any organisation in the world If what we believe of the powers of the scientific worker in industry is true, no better means could have been taken to ensure from the outset the prosperity of Britain's greatest manufacturing concern In Mond's own words, " my belief is that the chemist will solve the present economic and industrial problems of the world "

To understand Mond himself, one must know something of the altogether exceptional characters of his father, a scientific worker and an inventor first and last, and of his mother, a woman of unique artistic charm and vivacity and surprising brilliance of intellect He thus inherited a feeling for science and an appreciation for art which have at times prevailed over those qualities, requisite for a successful politician of the fighting type and an industrialist and financial magnate of the first order, by which the world knew and judged him and with which he was so richly endowed

As a consequence Mond was highly flattered by his election to the Royal Society, and he welcomed with pride the honorary degrees bestowed on him by St Andrews and Manchester, he took active interest in a number of scientific societies even when at his busiest in other ways, becoming, for example, founder president of the Institute of Fuel, president of the British Science Guild, and was designated president of the Society of Chemical Industry for its jubilee meeting this year, besides being always ready to lecture or otherwise help scientific institutions

In industry on the technical side, Mond had the widest possible views and great courage, he was able to grasp immediately the merits, demerits, and potentialities of the schemes put before him and, once satisfied, to ensure that they were immediately given practical effect Until recently it was as a politician that England knew him best, and no man has gone further in politics under greater personal handicaps Latterly it is as a politician, a leader of industry and an Empire builder combined in one man that he has won notoriety and fame He had the gift of going to the root of any question, grasping the realities and unmasking the shams—his extraordinary power of quick thinking enabled him to see round the corner of the problems of the day Underlying most of his public utterances it is possible to discern the spirit of science, and it is for the electors of the future to see that more men of his type represent them in Parliament Alfred Mond made use to the utmost of those gifts which he acquired by heredity

and by training, and his boundless energy enabled him to attain the very top in every field of endeavour he has passed away at the very height of his career His death on Dec 27 last is a loss that science as well as Great Britain can ill afford

E F ARMSTRONG

SIR FRANCIS OGILVIE, C B

SIR FRANCIS GRANT OGILVIE, who died suddenly at Edinburgh on Dec 14, at the age of seventy-two years, came of a family which had long been honourably associated with scholastic and scientific occupation He graduated M A at Aberdeen and B Sc at Edinburgh, and in 1886 was appointed Principal of the Heriot-Watt College, Edinburgh In 1900, he became Director of the Royal Scottish Museum of Science and Art at Edinburgh, and thus began that activity in museum administration which occupied the greater part of his working life

Three years later Ogilvie was appointed Principal Assistant Secretary for Technology and Higher Education in Science and Art at the Board of Education, and there began that close connexion with the museums and scientific institutions at South Kensington which continued for many years At that time, in his position under the Board of Education, matters relating to the Victoria and Albert Museum (by which title the South Kensington Museum had been known since 1898), the Royal College of Science, and the Royal School of Mines came before him, and consequently, when the scheme for forming the Imperial College of Science and Technology from the Royal College of Science, the Royal School of Mines, and the City and Guilds Engineering College was under consideration, the working out of the details and the drafting of proposals mainly fell to him to carry out

By 1908 the art collections of the old South Kensington Museum were safely housed in the new buildings of the Victoria and Albert Museum, but those illustrating science and engineering still remained in a part of the buildings which had originally been constructed for the Exhibition of 1862 On the initiative of Sir Henry Roscoe an influential and representative body of scientific men and leaders of industry brought to the notice of the Government the urgent need of adequate accommodation for these collections, and for their active development, with the result that in 1910 a Departmental Committee, under the chairmanship of Sir Hugh Bell, was appointed by the President of the Board of Education to consider and report upon the Science Museum and the Museum of Geology in Jermyn Street, Ogilvie being the secretary of the Committee In this capacity he got together the evidence for the Committee, and its report, which was published in 1911, set forth clearly the lines on which the Science Museum might advantageously be developed, and on which it has in fact been developed since then, although the War delayed this until he had ceased to be Director

On the death of Mr W Last in 1911, Ogilvie was appointed Director of the Science Museum, retaining also a certain administrative supervision of the Geological Museum and Survey, but the War put a stop to the construction of the new Museum buildings which the Committee had recommended and to the development which they had approved He then became Assistant Controller of the Trench Warfare Department and then later of the Chemical Warfare Department at the Ministry of Munitions, so that his reorganisation of the Museum had to be postponed Shortly after the conclusion of peace he became Principal Assistant Secretary to the Department of Scientific and Industrial Research from 1920 until 1922, when he retired

During his twenty years' work Ogilvie had acquired an unrivalled knowledge of all that had taken place in the course of the establishment and development of the various scientific and educational institutions which had grown up at South Kensington, and this was of great value to the governing bodies of many of them on which he served, namely, as a governor of the Imperial College of Science and Technology, as a commissioner of the Exhibition of 1851, and as a member of the Senate of the University of London

He was also the president of the Museums Association in 1927–28, and gave valuable evidence before the Royal Commission on National Museums and Galleries He held the chairmanship of the Geological Survey Board from 1920 until last year

---

PROF FRANTIŠEK WALD

THE prominent Czech chemist, Prof František (Franz) Wald, formerly professor of physicochemistry and metallurgy in the Czech Polytechnic High School of Prague, died on Oct 19 in Moravská Ostrava-Vítkovice, the well-known ironworks He was born in Brandýsek, near Kladno, and after studying in the German Polytechnic High School of Prague, whence he brought no theoretical bias, he devoted himself to technical chemistry, being for many years chief of the analytical and research laboratory of the ironworks in Kladno

While there, Wald published several interesting papers on the philosophical points of theoretical chemistry, especially "Die Energie und ihre Entwertung" (1889) Other of his important papers on thermodynamics were published in the *Listy Chemické* and in the *Zeitschrift für physikalische Chemie* His paper on the fundamental chemical ideas was read at the Philosophical Congress in Paris (1900), and was reprinted, together with his other papers, in Ostwald's *Annalen der Naturphilosophie* Owing to the originality and depth of his ideas, Wald was nominated in 1908 ordinary professor in the Czech Polytechnic High School, in which he was active up to the year 1927

Space does not permit me to give all the titles of Wald's philosophical publications, and it is also impossible to give a short account of his ideas, which were very original and therefore very different from what the great majority of chemists regard

as the fundamental notions of our science First of all, Wald was an 'anti-atomist', and so Ostwald, who was at that time (1901) 'anti-atomist' himself, included him in his well-known series of "great men of science" The doctrine of Wald is purely phenomenalistic, that is, it is devoid of any hypothesis concerning the reality of processes which would explain observed phenomena He worked out a theory of chemical stoichiometry based on the empirical laws of constant proportions, and, accepting the part that the composition of substances varies discontinuously, he was able to deduce the law of multiple proportions In his deductions Wald disregarded the difference between simple and compound bodies (that is, our elements and compounds), a chemical unit of water being, in its interior, just as homogeneous as is that of hydrogen or oxygen My objections, brought forward in a special meeting and based on the specific heats of gases and liquids, were disregarded by him, all 'bodies' were merely 'pure phases' to him, and he was original in explaining them by the use of the first up to the fifth dimension—of course, as said above, without the use of the atomic theory

Wald also enlarged Gibbs's ideas of phases, and deduced a modified phase rule in a simple and original manner To the question *cui bono?* the practical side of scientific chemistry will give no answer, but from the point of view of chemical philosophy his ideas may be regarded as splendid, something analogous to the views of the great philosopher Heraclitus, and they really both require 'a good swimmer'

BOHUSLAV BRAUNER

WE regret to announce the following deaths

Prof A A T Brachet, For Mem R S, Rector of the University of Brussels and director of the Laboratory of Embryology of the Faculty of Medicine in the University, aged sixty-one years

Major E A FitzGerald, author of "Climbs in the New Zealand Alps" and "The Highest Andes", on Jan 2, aged fifty nine years

Prof Hans Kniep, director of the Institute of Plant Physiology at Berlin Dahlem, on Nov 17, aged forty-nine years

Mr H A Lowe, honorary fellow of the Textile Institute, who discovered in 1899 the process of 'tensioning' mercerised cotton fibre, on Dec 26

Prof S G Navashin, of the Botanic Garden, Tiflis, Georgia, who was a foreign member of the Linnean Society of London, on Dec 10, aged seventy three years

Prof T Wibberley, formerly Harrington professor of agricultural research, University College, Cork, who was known for his work on the breeding and introduction of new varieties of oats and wheat, on Dec 22, aged fifty years

---

News and Views

THE New Year's Honours List contains the names of the following men of science and others associated with scientific work *Baron* Sir Ernest Rutherford, chairman of the Advisory Council of the Committee of the Privy Council for Scientific and Industrial Research, and until recently president of the Royal Society *Baronets* Sir John Rose Bradford, president of the Royal College of Physicians, Sir Richard Gregory, editor of NATURE *K C B* Dr F E Smith, secretary to the Committee of the Privy Council for Scientific and Industrial Research *K C M G* Hon Sir Walter Hartwell James, Chancellor of the University of Western Australia, Dr A W Hill, Director of the Royal Botanic Gardens, Kew *Knights* Prof C R Beazley, professor of medieval and modern history in the University of Birmingham, Mr W W Hornell, Vice Chancellor of Hong Kong University, Dr E G Graham Little, member of Senate of the University of London since 1906, Dr R W Livingstone, Vice-Chancellor of the Queen's University, Belfast *C B* Mr R L Hobson, Keeper of Ceramics and Ethnography, British Museum *C I E* Lieut Col H W Acton, director of the School of Tropical Medicine and Hygiene, Calcutta *C B E* Miss Caroline Haslett, director of the Electrical Association for Women and secretary of the Women's Engineering Society (Inc), Miss Edith Helen Major, Mistress of Girton College, Cambridge, Miss Louisa Martindale, president of the Medical Women's Federation and vice-president of the Medical Women's International Association, Prof Sidney Russ, professor of physics, Medical School, Middlesex Hospital, for work in connexion with radium, Mr J J Shaw, secretary to the Seismological Investigations Committee of the British Association *O B E* Dr W M Aders, lately economic biologist, Zanzibar, Mr R S Capon, Superintendent of Scientific Research, Royal Aircraft Establishment, Air Ministry, Mr J M Carey, H M Divisional Inspector of Mines, Mr J S Corbett, secretary of the Empire Forestry Association, Mr A de V Wade, principal assistant in the Native Affairs Department, Kenya *M B E* Dr V E Wilkins, Assistant Principal, Ministry of Agriculture and Fisheries

THE inclusion of the name of Sir Ernest Rutherford confers on the New Year's Honours List a quite unusual distinction One of the earliest of the distinguished band of research students who were attracted to Cambridge by the discoveries of Sir J J Thomson, he rapidly made his mark on physics Incidentally he was one of the earlier workers in wireless telegraphy, but it is with the science of radioactivity that his name has become inseparably linked Not only was he the first to recognise the complex nature of the radiations given out by radioactive substances, but he was also the first to unravel the knotty problems presented by the decay curves of these substances, and to enunciate the simple laws governing their disintegration In a few years he covered this field so completely that little was left for subsequent research save the filling in of details and the adjustment of a few constants If the value of a scientific theory is to be judged by its fertility, Rutherford's publication of his nuclear theory of the

atom must be regarded as one of the greater landmarks of science The conception of the atom as a miniature solar system having a central massive positively charged sun around which the electrons circulate like planets, was a bold one, as it had been demonstrated beyond doubt that a system of this type must be unstable on the generally accepted laws of electro dynamics

BY simple but cogent arguments, however, Rutherford succeeded in demonstrating that the planetary structure of the atom was the only one consistent with experiment, and a whole mass of unexplained and apparently unconnected observations crystallised into coherence around the new idea The theoretical work of Bohr and his successors, and the consequent rise of the new spectroscopy, were the natural and inevitable outcome of this new conception of the atom Leaving the problem of the arrangement of the electronic satellites to others, Sir Ernest has more recently launched a mass attack on the problem of the structure of the nucleus itself The difficulties in the way of determining the structure of a particle so minute that a million million of them could lie along a line a centimetre or so long are sufficiently obvious, but so skilfully has Sir Ernest directed the attack that a solution of the problem may be confidently expected in the very near future It is announced that Sir Ernest is taking the title of Lord Rutherford, and scientific workers everywhere will wish him health and long life to enjoy the title which he adorns

THE connexion of holders of the highest office in the Royal Society with the peerage of Great Britain provides some interesting reminiscences The Society began its presidency, in fact (after incorporation on July 15, 1662), with a peer of the realm, namely, Viscount Brouncker, who held office from April 1663 until Nov 30, 1677 He was a mathematician—the first to introduce continued fractions Huygens, in a letter to Oldenburg, congratulated the Society on having so eminent a mathematician for its president as Lord Brouncker, and Sprat the historian, his contemporary, says, "This office was annually renewed to him by election, out of the true judgment which the Society made of his great abilities in all natural and especially mathematical knowledge" From Nov 30, 1686, until the anniversary meeting of 1689, the Earl of Carbery was president He succeeded Pepys, and in the year following the death of Charles II, the founder Another peer was then chosen—the Earl of Pembroke, but his tenure lasted one year only He was three times married, too much occupied apparently to give attention to the Society, for his name does not appear as presiding, on any one occasion, at the council or ordinary meetings After two commoners had occupied the chair (Evelyn had twice declined), John, Lord Somers, Lord Chancellor, was unanimously elected president, the mantle devolving, moreover, on a bachelor A great and powerful figure, he filled the chair for ten years, presiding regularly over the council and meetings

LORD SOMERS resigned the presidency of the Royal Society to Sir Isaac Newton, who was followed by two other commoners, Sloane and Folkes The latter was succeeded in 1753 by the Earl of Macclesfield, who held office for twelve years He was mainly instrumental in procuring the change of style in 1752 His interests lay in astronomy and chemistry Altogether Lord Macclesfield was a brilliant personality in the Society's affairs, and, by the way, an upholder of pomp and ceremony He died in office on Mar 17, 1764 The Earl of Morton succeeded him, a distinguished patron of science In 1746 he had visited France and was for a time imprisoned in the Bastille Like the former president, he died in office, on Oct 12, 1768 Following the foregoing particular social attachments, seven commoners were successively elected presidents of the Royal Society, down to 1830, when the Duke of Sussex assumed the chair Afterwards, in order, were the Marquess of Northampton, the Earl of Rosse, and Lord Wrottesley Reverting to previous practice, eight commoners were in turn elected, all highly distinguished in various departments of science The eighth, Sir William Thomson, elected Nov 30, 1890, was made a peer (Lord Kelvin) whilst in office He was succeeded by Sir Joseph Lister, who was raised to the peerage (1897) whilst president of the Royal Society A commoner then took office (Huggins), and he was succeeded in the presidency by John William Strutt, Lord Rayleigh, who served from Nov 30, 1905, until Nov 30, 1908 Since that date no president has been raised to the peerage during his term of office

MAJOR A G CHURCH's action in voting against the Government in the division on the Dyestuffs Act has resulted in his resignation of his office as Parliamentary Private Secretary to Mr Tom Shaw, Secretary of State for War In a statement to the Press following his resignation, Major Church said that Great Britain is more dependent on the progress of science and the application of science to industry than any other country, and that prominent members of the Government have done service to this dependence in their public utterances Nevertheless, although most of the professional scientific bodies in the country, including the Association of Scientific Workers, of which he was general secretary, have expressed the opinion that the Dyestuffs Act should not be allowed to lapse until after the fullest inquiry has been made into the possible effects of any such course on the progress of the dyestuffs and allied industries and on organic chemical research, and although the experts in the Government Defence Services advocated the continuance of the Act, the Government decided to allow it to lapse, ostensibly in the interests of the textile trades This decision was reached without consultation with the representative scientific bodies concerned, and the Government did not even take the obvious course of referring the matter either to its own Advisory Council for Scientific and Industrial Research, or its Economic Advisory Council, or the Medical Research Council, or the Committee of Civil Research, in other words, the Government paid no regard to scientific opinion Major Church contrasted the Government's attitude towards scientific workers with its attitude towards the executive of the Miners'

Federation and the coal owners before and during the passage of the Coal Bill, and towards local education authorities, the teachers' organisations, and the religious bodies over the Education Bill Apparently, he said, in spite of the incalculable value of the work of men of science and the effect of science on the body politic, the Government felt they could be ignored because numerically they are insignificant and presumably their political influence negligible He voted against the Government deliberately in order to focus attention upon what he regarded as a grave fault of Government

FRIENDS of Dr C E P Brooks will be glad to hear of the award to him of the Buchan Prize of the Royal Meteorological Society in recognition of his numerous researches in the field of meteorology and climatology Dr Brooks is distinguished as the author of a large number of papers contributed to the *Quarterly Journal of the Royal Meteorological Society* and to the *Meteorological Magazine*, a number of official memoirs issued by the Meteorological Office, as well as of several books These works embrace such topics as the distribution of the weather elements in different parts of the globe and their correlation, sunspots and lake levels, forests and rainfall, weather periodicities, and British floods and droughts, with a large amount of statistical material invaluable to students of climate But Dr Brooks's most important scientific work is in the field of palæo climatology, wherein he has enlarged our ideas greatly, and in this field his book published a few years ago on "Climate through the Ages" occupies a prominent place in the very wide literature on the subject It is obvious that certainty about the past climates of this planet cannot be reached, but probability can, and it is not too much to say that Dr Brooks has given us a good indication not only of the major phases of climate which the earth has gone through in the geological past but also the minor phases that have preceded the present phase in our own islands Dr Brooks's cardinal principle that redistributions of land and water are quite capable of bringing about the changes of climate that are inferred to have taken place has been criticised, but it is probable that most climatologists will support this principle, particularly in cases where accumulations of ice and snow enter to complicate the situation Of the formidable power possessed by ice and snow to engender further cold Dr Brooks himself has provided a mathematical demonstration

THE Melchett Medal of the Institute of Fuel, for the year 1930, the first to be awarded, will be presented to Dr Kurt Rummel, of the Wärmestelle, Dusseldorf, at the Institution of Civil Engineers, Great George Street, Westminster, S W 1, on Friday evening, Jan 23, at 6 30 The Melchett Medal was instituted by the founder-president, the late Lord Melchett, who offered the Institute a few months ago a sum of money sufficient to found the medal in perpetuity It is to be awarded annually, "to such person, whether a member of the Institute of Fuel or otherwise, as in the opinion of the Council has done either original research, or professional, administrative, or constructive work of an outstanding character, involving the scientific preparation or use of fuel, provided the results of such work have been made available within recent date for the benefit of the community" Dr Rummel was born on July 1, 1878, at Aschaffenburg, Bavaria In 1919, he took charge of the Wärmestelle, Dusseldorf, of the Verein Deutscher Eisenhuttenleute At that period the contraction of the German coke producing areas under the terms of the Treaty of Versailles and the diminishing tonnage in the German mines in the producing areas led to a great scarcity of fuel for industrial purposes, and the Wärmestelle was formed primarily for improving fuel economy in iron and steel practice Much of the work of the Warmestelle, done under Dr Rummel's guidance, is of fundamental importance, and a wide range of papers embracing investigations dealing with problems relating to coke oven technology, blast furnace, open hearth, and rolling mill practice has been published Members of all scientific and technical societies are cordially invited to attend the presentation and lecture

THE ability of the electric arc to reproduce speech when the current from a telephone transmitter is superimposed upon it was demonstrated many years ago, and this peculiar form of loud speaker is well known as the 'speaking arc' On Jan 2, Mr J L Baird demonstrated to a representative of NATURE that under proper conditions the arc can be made to follow the normal rapid modulations of television A small arc lamp, upon which the television current had been superimposed, was placed behind an aperture in a diaphragm, the light from the arc being concentrated on the aperture by means of a lens A second lens was adjusted between the aperture and a revolving Weiller mirror drum with thirty mirrors, the lens and drum being arranged so that an image of the aperture traverses a screen of white board, forming a television image, the image being transmitted from the standard Baird transmitter used in the B B C daily transmissions The detail and definition of the received image were comparable to that received on the standard commercial television receiver, and the brilliance of illumination was remarkable This demonstration of the successful modulation of the arc with television signals appears to open up considerable possibilities The chief difficulty met with in the projection of television images on large screens has been the obtaining of a modulated light source of sufficient brilliancy Two methods have been used the neon tube and the Kerr cell The brilliance of the neon tube is not great, the Kerr cell gives more brilliant results, but it also has definite limitations With the Kerr cell system, light from a powerful arc lamp is passed through two Nicol prisms, between which is a vessel containing two adjacent electrodes immersed in nitro benzene The television signals are impressed upon the electrodes and vary the plane of polarisation, and thus the amount of light passing The efficiency of this device is very small, 50 per cent of the light is lost through polarisation, and

further losses are entailed in passing through the prisms By modulating the light of the arc directly, these losses are obviated, and the television arc would therefore appear to have a useful future

A PHYSICAL conception of the end of the world formed the basis of the presidential address delivered by Sir Arthur Eddington on Jan 5 before the Mathematical Association at the London Day Training College The world, or space time as Sir Arthur Eddington called it, was shown to be a four dimensional continuum, thus offering a choice of many directions to take in order to look for the end From a space dimensional point of view the world is spherical, but then the time dimension must be considered too This consideration formed the basis of the lecture Entropy, that is, the measure of the disorganisation of a system, was suggested by Sir Arthur as being the fundamental theme upon which to work Despite the phenomenon of evolution, whereby all types of systems have become and are still growing more highly organised, there is, on the whole, a general loss of organisation Such ever increasing organisation will perforce swallow up finally the organisation due to evolution Sir Arthur Eddington emphasised this conception, showing that finally the whole universe will reach a state of complete disorganisation, a uniform mass in thermodynamic equilibrium This would be the end of the world He considered finally what such an end would be like, but, realising that the doctrine of spherical space and the results connected with the expansion of the universe have become modified he merely made one of several possible suggestions Taking the widely supported hypothesis that matter slowly changes into radiation, he suggested that the world will finally become a ball of radiation, growing ever larger, with the radiation becoming thinner and assuming longer wave lengths About every 1,500,000,000 years the radius would be doubled, and this increase would carry on in geometrical progression

ACCORDING to an announcement in the *Times* of Dec 31, the collection of antiquities from the Roman Wall, formed by the well known Northumbrian antiquarian, John Clayton of Chesters (1792–1890), has been conveyed to a body of trustees for permanent preservation in Northumberland The collection will continue to be housed in the building erected for it in 1896 by Mr G N Clayton, subject to the goodwill of the present owner of the Chesters estate, Mr John Maurice Clayton, the donor to the National Trust of the fort of Borovicus (Housesteads), to whose generosity the present gift to the nation is due The first body of trustees includes Sir George Macdonald, Mr Robert Holland Martin, Mr R G Collingwood, Mr R Carr Bosanquet, and Mr Parker Brewis The collection is well known to archæologists as the finest assemblage of Romano British antiquities in the north of England and a most important source of information for the history of the Roman occupation of Britain It includes a large variety of objects in bronze, pottery, and other materials, as well as more than 300 inscribed or sculptured stones The famous "Chesters Diploma", a diploma of military discharge and citizenship on two fragments of bronze tablets, presented to the British Museum by Mr Clayton, is represented by a replica A statue of Cybele, a bas relief of the war-god, Mars Thingsus, and inscribed altars dedicated to Jupiter, Apollo, Mars, Cocidius, Antocidius, Vitiris, Huitris, Fortuna, and Minerva are noteworthy objects forming part of the collection

THE collection of objects at Chesters, from the Well of Coventina, 3½ miles distant, is of considerable interest to students of early British culture These include a sculptured stone stele dedicated to her by Titus Domitius Cosconianus, prefect of the first cohort of Batavians, another stele on which the goddess is represented with two attendant nymphs holding vessels from which pour streams of water, numerous altars dedicated to her and other deities, bronze brooches, bronze figures of a horse and a dog, and more than thirteen thousand coins which had been given as votive offerings at the well Coventina was evidently a water-goddess whose cult, judging from the number of offerings, must have been of considerable importance The writer in the *Times* cites Sequana upon the Seine and Damona at Bourbonne les Bains as similar cults of local water goddesses, but as their names indicate, these, like Coventina, were Celtic in origin The local cult of the water goddess was a characteristic feature of early Celtic religion and traces of such cults are to be found in many parts of Britain A noteworthy example was situated near Bath It is usually to be found, however that these goddesses have suffered a transformation, first into a god and then into a Christian saint, who becomes the patron of the spring or well, at which votive offerings have been made throughout the ages down to modern times

FOLLOWING its usual practice, the *Engineer* devotes a great part of its first issue of the year to a review of the technical progress which has taken place during the past twelve months in naval construction, electrical engineering, steamships and motorships, aeronautics, hydro electric engineering, and bridges Noting that seventy five years have passed since the *Engineer* was founded, it is remarked "As we glance back over the long period of our existence, we are unable to discover any year which resembles that which has just ended", and "we do not believe that in the whole history of the mechanical engineering and metal trades any parallel can be found for the conditions which now prevail" Admitting that for these conditions there is no single obvious cause, and that the complaint is practically world wide, the article touches upon matters affecting the industries of Great Britain, such as the attempt to maintain a higher standard of living than is perhaps justified, the possible effects of fiscal policies, and taxation, which is twice as high as in Germany, two and a half times as high as in Belgium, four times as high as in Italy, and twice as high as in the United States

THOUGH 1930 was not a fruitful year in the industrial field either at home or abroad, it holds to its

credit the completion of a few great civil engineering works, notably the closing of the arch of the great Sydney Harbour Bridge This bridge has a steel arch of 1650 ft span The Kill Van Kull Bridge between New Jersey and Staten Island is of the same type but with a span of 1652 ft An examination of the two bridges and the methods of erection show many differing features Another fine bridge is the *Montreal Harbour Bridge over the St Lawrence* River, the main span of which is a symmetrical cantilever having a length of 1097 ft from centre to centre of the main piers Good progress has been made with the Hudson River Bridge at Manhattan, New York, the steel wire cables of which have a total strength of 350,000 tons The span from the centres of the cable supporting towers is 3500 ft, and the total weight of the suspended superstructure will be no less than 90,000 tons When completed, the bridge will have two decks, the upper deck giving accommodation for eight lines of roadway traffic and two footways, while on the lower deck there will be two sets of two railway tracks Another bridge completed during 1930 but of an entirely different and very striking character was the ferro concrete arch bridge over the river Elorn at Plougastel, near Brest, the bridge having three main spans, each of which is 611½ ft from centre to centre

THE La Brea asphalt pits, not far from Los Angeles in California, have gained world wide fame on account of the extraordinary number of remains of sabre toothed tigers and other mammals which have been found embedded in them The census of skeletons of birds, just completed by Dr Hildegarde Howard, is scarcely less imposing From Science Service, Washington, D C, we learn that of more than 4100 birds recovered, 69 per cent are predatory species, and of these, diurnal birds of prey (2500) far exceed nocturnal forms (400)—evidence, similar to that yielded by the mammals, that most of the creatures caught in the glaur were in pursuit of others seen to be in difficulties Some extinct forms are in large numbers 500 individuals of the turkey, *Parapavo*, more than a hundred of *Teratornis*, a vulture larger than any flying bird of the present day, as well as numerous smaller extinct vultures The caracara, now confined to more southerly regions, is represented by 250 examples Many species still existing in California occur profusely—the American golden eagle with more than 880 individuals, the California condor 190, the bald eagle 150, the red-tailed hawk 113, great horned owl 104 Ducks and geese are fewer, in all less than 100, waders less than 60, two species of stork (one extinct, the other now a southern form), 28 individuals, 30 cranes, 8 herons, 2 ibises, and one grebe

THE annual report for 1929 of the Rockefeller Foundation, New York, recently issued, covers the first year of operations of the new Rockefeller Foundation, which, as foreshadowed in the report for 1928, is now constituted by the merging of the Rockefeller Foundation and the Laura Spelman Rockefeller Memorial into the new corporation The activities of the Foundation, formerly limited to the domain of international public health, have been extended and now include, in addition, the advancement of knowledge in the medical sciences, the natural sciences, the social sciences, and the humanities In the international health division, the work on malaria and hookworm disease prevention and investigations on yellow fever have been continued In the medical sciences, aid has been given to institutions, including the University of Oxford and St Bartholomew's and the London Hospitals, and to nursing institutions In the natural sciences, aid has been given to various biological institutes and for the support of *Biological Abstracts*, and a grant made to Prof Michelson for a re determination of the velocity of light In the humanities, the British Museum is to receive aid towards the publication of a new Catalogue of Printed Books

PROF G ELLIOT SMITH, who has just returned from a visit to China, will deliver a public lecture, with lantern slide illustrations, on Peking man, at 5 30 on Jan 15, at University College, London, W C 1

DR HERBERT LEVINSTEIN, chairman of council and past president of the Society of Chemical Industry, formerly managing director of British Dyestuffs Corporation, Ltd, has been awarded the Society's medal for 1931 The medal was awarded chiefly for his capable and valuable work in the dyestuff industry

AT the meeting of the London Mathematical Society on Thursday, Feb 5, at 5 P M, at Burlington House, London, W 1, Prof G N Watson will deliver a lecture on "Ramanujan's Note Books" Members of other scientific societies who may be interested are invited to attend

AN earthquake of moderate intensity was recorded at Kew Observatory at 10 h 1 m 44 s G M T on Jan 2 According to a message broadcast by the United States Coast and Geodetic Survey, the shock occurred near lat 18° N, long 108° W, under the Pacific Ocean about 300 miles from the Mexican coast The Kew observation agrees with this

IT is announced in the *British Medical Journal* that the Dr Sophie A Nordhoff Jung Cancer Prize for the best work of recent years in the field of cancer research has been awarded to Dr Alexis Carrel, of the Rockefeller Institute for Medical Research in New York, for his development of the method of tissue cultivation and his application of it in the solution of the basic problems of pathological growths, especially the growth of malignant tumours The commission of award was composed of Profs Borst, Döderlein, von Romberg, and Sauerbruch

APPLICATIONS are invited for the following appointments, on or before the dates mentioned —A Principal of the Doncaster Technical College—The Secretary, Education Offices, Doncaster (Jan 12) An assistant pathologist at the Sheffield Infirmary and demonstrator of pathology in the University of

Sheffield—The Registrar, University, Sheffield (Jan 14) Three assistants at the Acton Junior Technical School for, respectively, electrical engineering, mathematics and English, and machine tool practice, workshop processes, and mechanical drawing—Dr J E Smart, Education Offices, Acton, W 3 (Jan 17) Two assistants on the higher technical staff of the Science Divisions of the Science Museum, South Kensington—The Director and Secretary, Science Museum, South Kensington, S W 7 (Jan 24) A post graduate student at the Long Ashton Research Station of the University of Bristol for a special research on the synthesis of organic compounds—The Director, Agricultural and Horticultural Research Station, Long Ashton, Bristol (Jan 26) A teacher of marine engineering and a teacher of ship carpentry and boat construction at the Marine Industrial School, Suez—The Under Secretary of State, Ministry of Education, Cairo (Jan 31) A professor of engineering (mechanical engineering and motive power) at the Imperial College—City and Guilds College, South Kensington—The Academic Registrar, University of London, S W 7 (Feb 16) Three officers for the Forest Service of Burma—The Secretary, General Department, Office of the High Commissioner for India, India House, Aldwych W C 2 (Feb 16) A professor of botany and a professor of commerce in the University of the Witwatersrand, Johannesburg—The Secretary, Office of the High Commissioner for the Union of South Africa, South Africa House, 73 Strand, W C 2 (Feb 28) A temporary full-time assistant master for engineering subjects—The Principal, Technical Institute, Ashford, Kent Two officers for the regional organisation of broadcast adult education in Yorkshire and the West Midlands—The B B C, Savoy Hill, W C 2

ERRATUM —Prof L D Mahajan has pointed out that in line 6 of his letter entitled "Liquid Drops on the Same Liquid Surface" (NATURE, Nov 15, 1930, p 761), he gave the height of Den Kund incorrectly as 1000 ft instead of 10,000 ft

Our Astronomical Column

Large Fireballs —Mr W F Denning writes that on the early evening of Dec 27 last at 5 45 P M a large detonating fireball was observed from several parts of England Mr G H Brown, of the meteorological station at Horfield, Bristol, described the object as very large and bearing a broad train of sparks The fireball moved at a low altitude along the southern sky from east to west, it looked like a large firework and gave a very impressive spectacle It fell at an angle of about 30° The object was also seen on the east coast at Eye, and it traversed a course from under θ Aquilæ to beyond and under the three well known stars in that constellation Another record comes from near Finistère, in the north west of France, where the inhabitants were alarmed by the appearance of a great detonating meteorite

The observations show that the fireball passed over the north of France and must have suffered disruption and collapse in the neighbourhood of Finistère The real path will be investigated, and it seems that the radiant was either in Perseus, Auriga, or Orion, which have yielded large fireballs in past years from the same positions

The Finistère fireball was followed by another at 12 20 P M on the same date It illumined the heavens with a degree of intensity which startled some of the spectators One report states that the flight of the object was perpendicularly downwards in due west It ejected a stream of bright sparks as it descended, several people watched it, without, however, being able to record its exact place by the stars Its radiant point may have been in Auriga, but more observations are necessary It could scarcely have belonged to the system which supplied the brilliant apparition earlier in the night

Absorption of Light in Space —A paper by Dr R J Trumpler in *Publ Astr Soc Pacific* for August 1930 gives reasons for believing that there is a sheet of light absorbing matter distributed over the galactic regions and extending to a distance of 100 parsecs or more on each side of the central galactic plane This result was first arrived at by a study of the open galactic clusters and then confirmed from other material The amount of absorption is given as 0 7 mag at a distance of 1000 parsecs for light of wave length 4300 It is concluded to be less for red than for blue light, amounting only to 0 38 mag at 1000 parsecs for wave length 5500 It is noted in corroboration of this that the *O* stars, though probably the hottest of all, appear yellower than the *B* stars owing to their greater distance

From consideration of the possible mass of the interstellar matter, it is concluded to be not in separate atoms but in particles the mass of which is of the order of 2×10^{-19} gm (that is, some 3400 calcium atoms) There appear also to be free atoms of calcium and sodium to account for the fixed lines of these elements in the spectra of distant stars, but the selective absorption is not due to these The dark patches in the galaxy may be due to specially dense clouds of the general obscuring matter

Since the spiral nebulæ and the globular clusters are at a considerable distance from the galactic plane, their light traverses a comparatively short distance of the sheet of absorbing matter Hence their loss of light is small, and the distances derived on the assumption of no absorption are not greatly in error

The dark equatorial bands seen in many of the spiral nebulæ afford an additional argument in favour of the presence of a similar layer in our own galaxy

The Leonid Meteors —It has already been noted in this column that a fairly rich shower of these meteors was seen in North America on the morning of Nov 17 The *Daily Science Bulletin* of Dec 18, issued by Science Service, Washington, D C, states that a still richer display was seen on Nov 17 by G T Bieling, officer of the steamer *Annetta*, which was then near Porto Rico The display lasted from midnight (Eastern Standard Time) until dawn, being greatest at $3^h\ 40^m$ A M "One was a brilliant fireball, that exploded in a flash so bright that an excellent photograph could have been taken by its light A luminous trail was visible for 25 minutes"

These observations give some ground for hope that the rich portion of the Leonid stream has not finally deserted the neighbourhood of the earth, and that the next few Novembers may retrieve the general disappointment produced by the failure in 1899

The Azande Law of Legitimacy—Further impressions of the Azande are recorded by Major P M Larken in *Sudan Notes and Records*, vol 13 Zande law appears to be one of compensation, directed almost entirely to the satisfaction of the individual and, except indirectly, not safeguarding the rights of the community Death was the punishment for malicious magic and for concealing cases of smallpox, but beyond this, there was no idea of a malefactor suffering for having infringed the law established for the protection of the tribe as a whole Though for some offences a plaintiff might press for the death penalty, the majority of acts were compoundable by the payment of damages A man who wished to marry a girl addressed himself to her father or guardian The bride price was twenty spears, which was paid to the father and not to any other member of the family Children born without payment of spears were illegitimate and, as such, the property of the mother's family If they were girls, the mother's next of kin was entitled to the bride price Any boys among illegitimate children were entitled to their sisters' bride price which did not in that case go to the mother's next of kin A payment of only one or two spears was sufficient to legitimise the children, provided the balance was paid fairly quickly If the father refused to complete payment of the price, the chief would probably order the return of the woman with her children to her family, the father retaining one child in consideration of part payment of the bride price The father had a legal right to legitimise his children by paying spears, and his wife s family had no right to refuse Children of women captives of war, or given in payment of a debt or as presents by a former husband, were legitimate only if their father had paid the bride price for their mother

Earliest Cultures of the South-Western United States—Dr E B Renaud of the University of Colorado, describes the results of a series of explorations in caves and rock shelters of New Mexico and Oklahoma during the summer of 1929 in *L'Anthropologie*, T 40, No 3 The oldest remains from this part of the United States are those of 'Folsom man', a series of very fine lance heads found during 1927 and 1928 in the Folsom gravel pit in association with the bones of an extinct bison For these relics Pleistocene age has been claimed Of this early period, Dr Renaud's expedition of 1929 produced nothing but a fragment of an implement of the Folsom type The evidence points to a very primitive culture of a hunting people, probably with only temporary habitations Exploration of the caves of the fumaroles of the Cimarron valley established two horizons, separated by a considerable interval of time, of which the lower represented a long occupation by hunting nomads A considerable number of stone implements were found, which in their general appearance recall the Mousterian of Europe They were followed after an interval, represented in one cave by a layer of 20 cm thickness, by another people, who, though still hunters, seem to have made a greater use of vegetable foods, as is indicated by the presence of 'metates' for grinding seeds Next in the sequence comes the culture of the caves of Oklahoma, of which a number were explored at Kenton The stone industry in quartzite exhibits a great variety in form and purpose Though less coarse than that of the fumaroles, it is purely utilitarian and shows no effort to attain beauty of form These caves being dry, a number of objects of wood, sandals, basketry, and fibre work had survived These people had taken to agriculture, although still hunters Their culture is comparable to that of the Basket-makers Next in order came the volcanic caves of New Mexico, where was found a culture similar to that of the Oklahoma caves, with implements of stone, bone, and wood, the coarser character of the stone implements being due to use of inferior material The evidence for a rudimentary culture of maize was reinforced by male and female figures made from maize cobs, sometimes 'accouplés' and, therefore, obviously magical

Population Census—In view of the approaching census, it may be of interest to recall that Prof Raymond Pearl and Mr Lowell Reed published in 1920 a forecast of the population of the United States up to 2100 based upon data obtained by fitting a logistic curve to the census counts of the population from 1790 to 1910 Prof Pearl and Mr Lowell now compare their forecast with the actual counts of the 1920 and 1930 censuses (*Science*, Oct 17, 1930, p 399) The forecast figures in millions were 107 4 for 1920 and 122 4 for 1930, the actual census figures being 105 7 and 122 7 respectively The forecast thus missed the counted population by 16 parts in a thousand in excess for 1920 and by 2 5 parts in a thousand in defect for 1930

Chinese Ants—Prof W M Wheeler (*Bull Pekin Nat Hist*, vol 5, pp 53 81, 1930) states that the Chinese ant fauna is a mixture of two components one of which is Palæarctic and the other Indo Malayan and representing a northward and eastward migration of species from Indo China, Siam, Burma, and India The ant faunas of Japan and Formosa exhibit a similar mixture of two components the Palæarctic being greatly in excess of the Indo Malayan in Japan, and the Indo Malayan greatly in excess of the Palæarctic in Formosa This island possesses a considerable number of endemic species of palæotropical affinities, but endemicity is meagre in the ant fauna of Japan, indeed, so many of the ants formerly supposed to be peculiar to Japan have been found in China that the species of the two countries may be said to constitute a single fauna—the Sino Japanese The list of Chinese ants which follows includes 138 species, 54 sub species, and 53 varieties, for each of which the author gives a reference to the original description, cites the type locality, and mentions the Chinese localities from which material has been received The Palæarctic component comprises 29 species, 11 sub species, and 16 varieties—about 23 per cent of the entire fauna The remainder is the Indo-Malayan component

Development of the Rabbit Embryo—In *Contributions to Embryology* (vol 21, 1930), issued by the Carnegie Institution of Washington, Mr P W Gregory gives a vivid picture of the earlier stages in the formation of the embryo of the rabbit By applying an exact technique to a very large number of pregnant does, he has confirmed an observation made by Dr Martin Barry in 1839 that the egg is shed from the ovary and enters the oviduct 10 hours after coitus, and that the male element fertilises the egg 2 hours later In 10½ hours after fertilisation the egg is undergoing its first cleavage, in 2 hours more it is forming its 4 celled stage, in another 6 hours it has passed into the 8 celled stage, the 16 celled stage is entered at the end of the second day following coitus At the end of 70 hours, counting from the time of coitus (60 hours from fertilisation), the ovum passes from the oviduct into the uterus, being then in its 16 celled stage At the time of this passage the ovular mass has become differentiated into an inner

cell mass enclosed within a surrounding protective envelope of the trophoblast. The author pays a tribute to the exactness of a similar investigation which the late Prof. Assheton, of Guy's Hospital, published in 1894.

Effects of an Epicaridan Parasite.—B. W. Tucker (*Quart. Jour. Micr. Sci.*, vol. 74, part 1, Sept. 1930) points out that the effects of epicaridan isopods on their hosts have not hitherto been studied in detail. He found in Naples in 1924 that 21·5 per cent of the specimens of the burrowing decapod crustacean *Upogebia* were parasitised by the epicaridan *Gyge branchialis*. Fixation of the parasite to the host normally takes place when the latter is 17 mm. in length. The length of life of *Upogebia* appears to be about three years, and that of the parasite is normally coextensive with that of its host. The effect of the parasite on the general vitality of the host is negligible—moulting and growth are not materially affected. Parasitised male *Upogebia* have chelæ agreeing in size and appearance with those of the female, and they develop the appendages of the first abdominal segment which are normally present in the female only. Parasitised females are unaltered externally. Scattered oocytes occur among the male germ cells in the testes of many normal males, and are eventually shed into the lumen of the testes, where they degenerate. Whether they arise from modified spermatogonia or are distinct from the outset was not ascertained. The testis in parasitised males shows all stages from slight reduction to complete atrophy and the tendency to develop oocytes is much accentuated; in a few cases a tract of testis appears to have been completely converted into ovary. In the large majority of parasitised females the gonad is entirely absent; in the remainder the ovary is in a state of diminished activity but not otherwise abnormal. The modifications of sex characters in parasitically castrated Crustacea are exclusively in the direction of feminisation and cannot be interpreted as a return to primitive or juvenile features. Geoffrey Smith's theory—that the parasite, by withdrawal of nutriment, reacts on the host in a manner similar to an adult ovary—is considered to be the only one which makes any approach to a real explanation.

A New Tetraploid Species-Hybrid.—Three cultivated species of the Convolvulaceous genus *Quamoclit* have been studied by Sigeroku Nohara (*Jour. Coll. Agric. Imp. Univ. Tokyo*, vol. 11, No. 1), who has also studied their hybrids. *Q. coccinea* and *Q. pennata* differ markedly in cotyledon and leaf form as well as flower shape and colour. The F_1 is in general intermediate and sterile. There are also two forms of *Q. pennata*, one having rose red flowers and the other a corolla which is white tinged with dilute greenish yellow. The F_1 of the hybrid between these forms is also intermediate. A third species, *Q. sloteri*, has been much more recently introduced into Japan. It appears to have been collected first in America in 1849 by George Englemann, of St. Louis. Dr. Kano has determined the chromosome number of this species as 30 (haploid), and that of the other two species as 15. Hence *Q. sloteri* is tetraploid. It has larger pollen grains than the other species and is probably a cell giant. It resembles in many respects the (sterile) F_1 hybrid obtained by Nohara by crossing *Q. coccinea* with *Q. pennata*, but is stouter and fertile. Hence it is probably a hybrid species, having arisen either in Nature or under cultivation by chromosome doubling in the sterile F_1 hybrid. *Q. sloteri* is now a fixed race, but it gave rise in cultures to a reversionary type resembling the F_1 of *Q. coccinea* × *Q. pennata*. The chromosomes of this plant were not counted, but it was probably diploid. *Q. sloteri* crossed with *Q. coccinea* also gives sterile hybrids which will no doubt be found to be triploid.

The Scientific Pruning of Vines.—"The Fruiting Habits and Pruning of the Campbell Early Grape" is the title of *Technical Bulletin* No. 106, published by the Agricultural Experiment Station of Michigan State College. The writer is N. L. Partridge, who has treated his subject very thoroughly. Studies on the relation to the yield of fruit of current season's growth, diameter of shoot, position of the fruit on the canes, size of cane, internodal length, and other factors have been made, and the results considered in relation to practice. The variety 'Campbell Early' yields most good produce from large diameter shoots, whilst its sister variety 'Concord' produces its best bunches on shoots of moderate size. It is best to leave about fifteen internodes on shoots of 'Campbell Early'. Shortening beyond this length materially reduces the yield. If the vine will not support four canes of this size, it is better to reduce their number rather than to shorten them. This knowledge is very valuable, for it introduces the grower on one hand, and the scientific worker on the other, to a much neglected field of inquiry. It would be very helpful if we had similar studies of our English horticultural plants, coupled with detailed biochemical investigations.

A Disease of the Douglas Fir.—The genus *Phomopsis* has provided many puzzles for mycologists in the past, and our lack of knowledge became acute when it became necessary to differentiate *Phomopsis Pseudotsugæ*, a disease of the Douglas fir, from other closely allied fungal parasites. A detailed study of the genus by G. G. Hahn (*Trans. Brit. Mycol. Soc.*, vol. 15, parts 1 and 2, pp. 32-93, 1930) has done much to elucidate the facts concerning such species as attack conifers. Eight of the latter have been described in great detail, and a dichotomous key has been devised to separate them. *Phomopsis occulta* has been proven the same fungus as *Diaporthe conorum*, thus adding weight to the prevailing idea that *Phomopsis* represents an imperfect stage of *Diaporthe*.

Salt-Plugs in Southern Persia.—An important paper by J. V. Harrison on the salt-plugs of Laristan has appeared (*Quart. Jour. Geol. Soc.*, vol. 86, pp. 463-522, 1930). The extrusive salt has come to the surface at different periods from Oligocene to Pliocene, has formed hills and salt gypsum 'glaciers', and after erosion has in some cases left great corries in the limestone mountains of the region. The salt always comes up from below, and in widely different localities of the Persian Gulf territory has brought up with it Middle Cambrian fossils, as well as boulders of rocks which have no parallel in the succession of exposed systems from Ordovician to Pliocene. The salt plugs lie in the autochthonous area in front of the South Persian nappes, and it is suggested that they originated where compression acted upon mobile salt and gypsum beds of Cambrian or even greater age. Compression may arise from tangential pressure or from the weight of the overlying strata, but once the salt has accumulated at an underground nucleus, it is still not clear what was the source of the energy that drove the salt to the surface. The hypothesis of salt movement through solution and recrystallisation is no longer accepted. The salt has responded to external forces as a plastic material, and the resulting tectonics are transitional between the disharmonic folding of less mobile incompetent strata and the intrusions of more mobile igneous magmas.

Partial Absorption of X-Rays.—The issue of the *Zeitschrift für Physik* for Nov. 27 contains a paper by Dr. B. B. Ray, in which he describes with some detail his experiments on the partial absorption of X-rays. This effect, to which several references have been made in NATURE recently, appears to consist in the transfer of energy from an X-ray quantum to an electron in a light atom without important deviation of the quantum. The spectra have been recorded photographically with a Siegbahn vacuum instrument, and the paper is illustrated by reproductions of three plates, which show unambiguously the lines in question. Dr. Ray mentions that these are not coincident with lines which might have been produced by impurities, and that they are also distinguished by being somewhat diffuse. The width of the lines is stated to correspond, in order of magnitude, to the ionisation potential of the absorbing atoms, and the conclusion is reached that the electron responsible for the change in energy of the radiant quantum may be transferred to an optical energy level of the atoms, or expelled with zero velocity. Dr. Ray adds some remarks on the apparent magnitude of the absorption coefficient of X-rays when various dispositions of apparatus are made, and upon the *J* phenomenon.

Black-Body Radiators.—A. C. Egerton and M. Milford describe two forms of black-body radiator in their paper on optical pyrometry in the December number of the *Proceedings of the Royal Society* which, although not completely novel in principle, afford simple and relatively inexpensive sources of full radiation. The first consists of a wedge of thin platinum foil which is heated electrically, either in a vacuum or in hydrogen or argon. With an angle of 10°, such a system is known to be within less than one per cent of 'black'. The other consists of a tube of platinum (1.4 mm. external diameter, 10 cm. long and 0.15 mm. thick) with a 0.3 mm. hole in the middle of the wall, through which the internal black-body radiation can be investigated. Both forms were used with various minor modifications, temperatures being preferably determined by the melting of wires hung down the middle of the tube. A monochromatic filter, for which a 'didymium glass' is employed, is also described, transmitting a band of light between 5740 A. and 5600 A.

A Differential Ebullioscope.—Under the title "Construction of a Differential Ebullioscope for determining the Purity of Individual Liquids and of Azeotropic and Eutectic Mixtures", Prof. W. Swietoslawski, of the Warsaw Polytechnic, describes (*Roczniki Chemji*, **10**, p. 570, 1930) a new type of ebullioscope. It consists essentially of two similar sections so that the vapour formed when the liquid in the lower part is heated then passes through the upper section, the object being to observe both the boiling point, tH, and the condensation temperature, tB. Prof. Swietoslawski also describes a micro-ebullioscope for the study of relatively small quantities of liquids. The special advantage of this ebullioscope is that it enables a careful study of the boiling temperatures of pure solvents and of 'constant boiling' mixtures to be made. Furthermore, it is shown that the boiling point, tH, and the condensation temperature, tB, are identical when no impurity is present. With his collaborators the author has examined a number of pure liquids and azeotropic and eutectic mixtures, temperatures being measured by a small Beckmann thermometer and also electrically. For methyl alcohol (Poulenc) $tH - tB = \Delta t = 0.043°$ C., methyl alcohol (Riedel de Haën) showed $\Delta t = 0.023°$, whilst a German preparation had $\Delta t = 0.000°$. When, however, the last sample was allowed to stand for several months in the apparatus, it showed a difference of 0.052° C. Toluene-free benzene (Merck) also had $\Delta t = 0.000°$; toluene (Merck's "chemically pure" for molecular weight determinations) gave $\Delta t = 0.040°$, whilst purified and dried carbon disulphide gave at first $\Delta t = 0.008°$, and after a further purification, $\Delta t = 0.000°$.

Crystalline Modifications of Electrolytic Chromium.—Bradley and Ollard (NATURE, **117**, p. 122, Jan. 23, 1926) stated that chromium prepared by a special method is a mixture of two allotropes, a body-centred cubic form and a hexagonal close packed form. Later workers, however, reported that the electrolytic deposit consists only of the body-centred cubic structure. In the *Journal of the Society of Chemical Industry, Japan*, November 1930, vol. 33, No. 11, however, Sasaki and Sekito state that they have confirmed the existence of both the forms described, which are produced by the method of Ollard, and they have also found another modification of the same type as α-manganese, with 58 atoms in a unit cube. X-ray methods were used and details of the lattice structures are given.

Organic Compounds of Gold.—Diethyl gold bromide, $Au(C_2H_5)_2Br$, first described by Pope and Gibson in 1907, is shown by Gibson and Simonsen, in the November number of the *Journal of the Chemical Society*, to have a doubled formula in benzene solution. In the associated form the gold atom has a completed octet of electrons. Experiments are described which show that gold in these compounds has a co-ordination number of four, and a slow hydrolysis of the compound in water is assumed to be due to the formation of an aquo salt, $[Et_2Au(H_2O)_2]Br$, giving the reaction for the bromine ion. Amino diethyl gold bromide, $(C_2H_5)_2AuBr,NH_3$, and pyridino diethyl gold bromide, $(C_2H_5)AuBr,C_5H_5N$, the first compound being previously described by Pope and Gibson, were prepared. They are colourless, highly crystalline compounds with similar properties, sensitive to light, soluble in organic solvents, and almost insoluble in water. Other interesting compounds, such as diethyl gold acetyl acetone, are described in the paper.

Stereochemical Influence on Substitution.—Mills and Nixon in the November number of the *Journal of the Chemical Society* describe some experiments with substitution derivatives of δ-hydroxy hydrindene which have a bearing on the configuration of the carbon valencies in the benzene ring. If, in a doubly bound carbon atom, the angle α between the two single bonds is the same as that between the valencies of the carbon atom in methane, 109.5° according to the tetrahedral theory, then the angle β which the single bonds make with the plane of the double bonds would be 125.25°. On the assumption that the external angles are increased approximately proportionally when the internal angle of each CH residue is reduced to 120° in the formation of a Kekulé benzene nucleus, the angle α which each of the external valencies makes with the intranuclear single bond on one side of it is less than that, β, which it makes with the plane of the double bond on the other side. In compounds in which the benzene ring is fused with appropriate five-membered rings, the stable compound will be that in which the linking common to the two rings consists of a single bond, since this will be under the less intramolecular strain caused by the approximation of the intervalency angles to 108°. The effects of fusion of a benzene ring with six-membered rings are also considered. The experiments described in the paper are held to confirm the results anticipated from theory.

Early Human Types and Culture Sequences in South Australia.

PRELIMINARY observations on two adjacent sites in the Lower Murray Valley which have an important bearing on the antiquity of man in South Australia are described in vol 4, pt 2, of the *Records of the South Australian Museum*, by Mr Herbert M Hale, curator, and Mr Norman B Tindale, ethnologist of the Museum The sites are in the neighbourhood of Old Devon Downs, seven kilometres below Nildottie township One was an island, Tartanga, between the river and a lagoon, the other a cliff shelter opposite Old Devon Downs station and a kilometre and a half west of Tartanga, the existence of which had already been reported by Sheard in 1927 In the same year a human skeleton was found by Mr A R Roy embedded in sand rock in this part of the Murray Valley and it was decided to undertake the examination of the sites Operations began in April and were continued in November and December 1929

At Tartanga, beneath four layers of 'recent' deposits, five consolidated strata were examined, of which the lowest and earliest, *A*, represented the lagoon shore, while *B* to *E* above represent successive surfaces of an old island now nearly eroded on the western side of the lagoon All show signs of human occupation except *F* and *G*, which are practically sterile Borings below *A*, which was not very deeply excavated, suggest that there are at least two further strata below with signs of human occupation

Of the five consolidated strata *A*, the lowest, though not extensively examined, yielded burnt stone, suggesting hearths, stone chippings, and shells of mussel (*Unio*) In the strata *B* to *E*, among the food debris were quantities of mussel shell (*Unio proto vittatus* n sp, which differs in having a uniformly thicker shell from the *Unio vittatus* now common in the adjacent lagoon), jaws and vertebræ of fish, fresh water tortoise, birds (unidentified), and bones of mammals (opossum, wallaby, kangaroo) Flakes, chippings, and implements of stone and bone occurred throughout the layers Skeletal remains representing three individuals, including the skeleton found by Mr Roy, were recovered An examination of the dentition, possible in two cases, showed that it was superior to that of the present Australian aborigines and belonged to children of from ten to twelve years of age The remains were mineralised and firmly embedded in the matrix Above the sterile strata *F* and *G*, *H* showed hammer stones and high backed knives similar to implements known to aborigines now living near Lake Eyre, while *I* showed traces of recent occupation

In the cliff-shelter the deposits were excavated to a depth of four metres, and in twelve successive layers showed four cultural stages Skeletal remains of several individuals were found—all children In one case, found in the third layer from the top, the teeth showed strongly marked simian characteristics

The cliff shelter cultures follow the Tartanga culture after a considerable but undetermined interval The first two culture phases have been named 'Pre Pirrian' and 'Pirrian', the latter being characterised by a leaf-point artefact with retouched edges and prepared butt which has been christened 'pirri', a well-known type on old camp sites in many parts of South Australia but not observed among living tribes This culture was followed suddenly by a people who apparently at first fed largely on the small mammals of the plains, but nevertheless possessed double pointed fusiform fishing bones, 'muduk', whence the culture is to be called 'Mudukian' This culture was rich in stone and bone industries It was followed by the 'Murundian', so called from a local sub tribe, and divided into an early and late phase, of which the latter may represent the culture of the district when first visited by the white man Local native legends indicate that within tribal memory there has been a southward movement of people from up the river It would seem that if this movement is linked with Murundian levels, the latest cultural phase has not extended to the coastal parts of eastern Victoria, where the people of a somewhat earlier phase, possibly Mudukian, existed until the present time Contemporary with Mudukian and Murundian, early and late, are rock markings which show three distinct types The occupation of the shelter was sufficiently long to admit of a number of faunal changes, possibly due to climatic variation

The interest of the investigation of these two sites lies only partly in the fact that they are the first old camp sites in Australia on which a cultural sequence has been worked out in association with human remains after an excavation which has been conducted in strict accordance with archæological methods, Tartanga has an additional importance in the fact that it has been suggested, after an initial comparison, that the Tartanga human remains when examined in further detail may be found to represent a type intermediate between the modern Australian aboriginal and the Talgai skull, which is claimed to be of Pleistocene age

Noise and its Measurement.

THE Noise Abatement Commission, Department of Health, City of New York, has now published the report of the committee appointed by Dr Wynne on the noise in New York City and on the best way of diminishing it It gives the results arrived at by experts in neurology, otology, law administration, acoustics, engineering, and the motor car industries They have definitely established laws which have hitherto only been vaguely suspected The committee has effected some progress in the direction of noise abatement

The shipping companies have co operated with the committee in diminishing the noises of steam whistles and sirens The drivers of mail motor vehicles have instructions that their horns are only to be used for the purpose of preventing accidents Noiseless turnstiles have been invented and are being used at several railway stations The Health Commissioner and the police have special powers to control the indiscriminate use of loud-speakers

In addition to getting the law amended, engineers have been encouraged to invent less noisy machinery and motor cars The Press also is educating the public to realise the costliness and danger to health due to much needless noise It is pointed out that the noise in cities like London, Paris, and Berlin is not nearly so nerve racking as the noise in New York The erection of buildings goes on much more leisurely, and in European cities there is little complaint from neighbours about harsh and blatant loud-speakers and there is little outpouring of radio programmes into the streets day and night It is said that taxi drivers in New York are becoming hard of hearing, and that boiler workers and other

mechanics exposed to a constant riveting noise are also becoming very deaf

The absolute amounts of energy in the sounds of ordinary experience are exceedingly small in comparison with those of other forms of energy For example, the power equivalent of more than one million voices is necessary to light an ordinary electric lamp The average speech power of the loudest single voice is about 1000 microwatts, and this falls to 0 1 microwatt for the quietest speech and to about 0 001 microwatt for the softest whisper However, in most energy measurements of applied acoustics the interest lies not so much in the intensity of the sounds as in their loudness, that is, in the intensity effect produced upon the ear by them, and further, it is well known that the increase in power necessary to produce a perceptible increase in loudness depends upon the initial intensity of the sound

From these considerations it is clear that in problems concerned mainly with power differences, whether acoustic or electric, a special unit is convenient, and that now being adopted in telephony is the *bel*, so named as a tribute to the inventor of the telephone Two amounts of electric or acoustic power P and P_0 are said to differ in power level by n bels if $n = \log_{10}(P/P_0)$ The most convenient unit for most practical work is one tenth of the bel, the *decibel* (db) known also as the *transmission unit* (T U) Further subdivision of the bel is unnecessary, since a change of the power level of a sound by one decibel is about the smallest which can be detected by ear It is unfortunate that another term, the *sensation unit*, is used in this connexion for the decibel by otologists, psychologists, and physiologists Since, for pure tones, equal steps on the logarithmic scale sound approximately like equal loudness stops, and since a power change of one decibel is approximately the smallest such step detectable by ear, the sensation level of any sound reaching the ear is conveniently represented by the number of decibels it is above the threshold level for audition In this connexion the term sensation unit is often used instead of decibel

An idea of the size of the decibel can be obtained from some actual examples If, in the discussion of speech power, the average speech power be taken as the zero level for comparison, then the level of very loud speech would be +20 db , of weak speech −20 db , and of a soft whisper −40 db In measurements made on many speakers it has been found that the range of average powers used in conversation by the majority is about 21 db Measuring from the limit of audibility, speech would be received at a level of 100 db if the lips of an average speaker were within half an inch of the ear of a person having normal hearing Measuring from the same level, the roar of street traffic in a city would be received at a level varying from 50 db to 80 db , and the noise of an underground tube train passing a station at about 96 db Two special gramophone records have been prepared in the Bell Telephone Laboratories, New York, in which the same complex sounds can be heard at different levels (see NATURE, 125, 394 , 1930)

The Antiscurvy Vitamin in Apples

A BRIEF reference has already been made in these columns to a preliminary report by Zilva and his associates of their work on the antiscorbutic potency of apples (NATURE, vol 126, p 248 , 1930) The full experimental details of this research have now been published *

In spite of much work on the properties of vitamin C, success has not yet attended attempts at its isolation it is known, however, to be very susceptible to oxidation but to be stable to heat in the complete absence of oxygen Its behaviour depends in part also on the presence of other substances in its natural sources , thus in lemon juice a reducing factor helps to maintain its activity, and destruction of this factor always leads to loss of potency Deterioration of heated lemon juice is rapid on storage, and autoclaving the juice results in the appearance of a destructive factor (Zilva, *Biochem Jour*, vol 23, p 1199 , 1929) It is not destroyed by fermentation and is most stable at the natural acidity of the juice , but is unstable under conditions detrimental to the growth of moulds and bacteria (J Williams and J W Corran, *ibid*, vol 24, p 37 , 1930) It is precipitated by basic but not by neutral lead acetate , its activity is not dependent upon the presence of amide nitrogen, but iron, phosphorus, and sulphur are present in the most concentrated preparations so far obtained, though whether these elements are related to the potency is not known It has been suggested that it is a weak acid (R B McKinnis and C G King, *Jour Biol Chem*, vol 87, p 615 , 1930)

Since chemical purification leads to increasing instability, indirect methods of approach, such as the establishment of a relationship between the antiscorbutic potency and the physiological condition of a plant, would at any rate increase our knowledge of the vitamin's properties and might even lead to its isolation Zilva and his associates, therefore, have begun an investigation into the antiscorbutic activity of different varieties of apples, grown under different conditions and stored for varying lengths of time Their results, although of a preliminary nature, have led to some interesting conclusions The work is laborious, since all tests have to be carried out on guinea pigs , the animals are given a diet of bran, barley meal, middlings, fish meal, and crushed oats together with autoclaved milk, on which, if no source of vitamin C is provided, they die from scurvy in 4 5 weeks

Different varieties of apple were found to differ considerably in their antiscorbutic potency Bramley's Seedling was the best, a daily dose of 3 gm preventing the onset of scurvy and usually permitting of a fair amount of growth , King Edward had the lowest potency, a daily dose of 20 gm failing to prevent the onset of scurvy, although it prolonged life The protective doses of other varieties were Dabinett, 10 gm , Woodbine, 20 gm , Cox's Orange Pippin, slightly more than 20 gm , whilst for Worcester Pearmain, 20 gm failed to give complete protection No relationship was detected between antiscorbutic potency and the age of the tree, the soil or the season, or the date of picking the fruit

Slight loss of potency occurred on storage at 1° C in air, and a slightly greater loss was observed at 10° C in an atmosphere containing 10 per cent carbon dioxide, 11 per cent oxygen, and 79 per cent nitrogen Bramley's seedling survived storage, especially gas storage, better than Cox's Orange Pippin A number of imported varieties were also tested, and it was found that Canadian were more active than Australian or New Zealand probably due to the fact that the time between picking and test was greater in the case of the latter

* 'The Antiscurvy Vitamin in Apples By Mary F Bracewell, E Hoyle, and S S Zilva Medical Research Council, Special Report Series, No 146 London H.M Stationery Office, 1930 Pp 45 9d net

The effect of heating fresh and stored apples in their skins at 115° C in air for 50 min was studied no significant loss in potency was observed Some chemical analyses were also carried out In general, the chemical composition of the different varieties was very similar but in some preliminary experiments it was noticed that the nitrogen content of King Edward was about twice as great as that of Bramley s Seedling

In conclusion, the authors point out that the high antiscorbutic value of Bramley's Seedling, fresh or stored, cooked or uncooked, is of interest to the dietician, but that the lower potency of other varieties scarcely lessens their nutritive value, since they are consumed under conditions in which the vitamin C requirements are usually fully covered by the general diet

Industrial Health Research Board

THE tenth Annual Report of the Industrial Health Research Board contains an account of the work done during the year 1929 The report is divided into two sections the first dealing with problems of general industrial importance and the second with more specific problems submitted by Government departments and industrial associations

In the first section an account is given of researches into (a) Heating and ventilation and in this connexion it is stated that rooms heated by under floor and ceiling panel systems feel warmer and more comfortable than rooms heated by stoves or hot water radiators and it is claimed that these systems have certain advantages in factories and for open and semi open air schools

(b) Vision and lighting Further experiments are reported on the use of special spectacles in very fine processes, and a very interesting research shows that even coarse work can be substantially improved by increasing the illumination Arrangements are also being made to study the effect of natural ultra violet radiation on factory workers

(c) Noise and vibration studies have so far revealed little in the way of positive results

(d) Accidents causation researches have been still further extended and the results of tests on 1800 subjects are recorded The original conclusions, published previously have been in the main substantiated namely that there are certain workers who are prone to accidents and that these may be detected by tests It would be interesting to know if the people who have street accidents are of this type

(e) The problem of sickness absenteeism is receiving attention from several angles On one hand, there is a general study in progress of the actual sickness occurring in different firms, and the medical diagnoses while on the other, absenteeism among special groups for example, coal miners, printers, cardroom operatives A difficulty in this field is that relatively few firms have as yet realised the importance of accurate detailed sickness records Closely linked up with this problem is that of psycho neurotic illness, and a special investigation of psycho neurotic symptoms among industrial, clerical, and professional occupations is in progress

(f) Other studies relate to the physiology and psychology of work, and to the occupational fitness of mental defectives

The second section describes work done on problems submitted by Government departments and industrial associations The sickness investigations among printers and others have already been mentioned In addition there is an account of the effects of baths at the pit head and various investigations on the fundamental principles underlying vocational tests It is hoped to discover what qualities a candidate possesses rendering him more suitable for one occupation than another

Some researches, owing to the nature of industrial conditions, cannot be conveniently followed in a factory and in these circumstances arrangements are made with various universities to obtain special laboratory conditions The problems of this kind reported refer to the extent to which acquired skill is transferred from one process to another, the relative effects of concentrated and distributed practice, the characteristics of learning curves the effects of variety and uniformity in work, and the influence of incentives

The Board concludes with an appeal for a wider interest in its work and in its practical applications

Development of River Systems

THAT a river may be diverted by the capture of its headstreams by a neighbouring river has been regarded as well established since the famous paper of Beete Jukes (1862) on the river system of southern Ireland This process has been applied to explain the developments of river systems in all parts of the world, but it is now declared to be impossible on any material scale, by Dr E O Marks, of the Geological Survey of Queensland (*Proc R Soc Queensland*, 1930)

Dr Marks rests his case on a detailed study of the rivers of Queensland The watershed between those that flow inland and those that go eastward to the coast is inappropriately called the Great Dividing Range, which Dr Marks justly rejects He points out that the Queensland Divide has been in places lowered 1000 ft by denudation, and yet the lateral displacement is so trivial that it amounts only to minor nibbling In two cases (the Fitzroy and the Burdekin) the change is more important, as those rivers once flowed west whereas they now discharge east, but this change he attributes to their having overflowed the divide and thus cut it down He calls this river-dumping, not river capture, and says it is not due to encroachment upstream

From the evidence of eastern Queensland Dr Marks argues that the ordinary physiographic view is incorrect, since he holds that denudation by rivers and waterfalls is only vertical and makes no serious encroachment upon the head of the river River capture he declares improbable, and the development of reversed obsequent rivers impossible, and he claims that as watersheds are fixed, 'all that part of physiographical theory which depends on their migration must be discarded

The paper directs attention to the usual nature of the main Queensland divide, its special character appears due to the subsidence of the coastal region, as illustrated by the formation of the Barrier Reef and that it is recent is obvious from the nature of the Barron Falls Australia has provided striking cases of watershed migration The intricate dove tailing of the northern and southern river basins in the Victorian Highlands—where the main watershed has also been called the Main Dividing Range—is due to great changes in the position of a divide by rivers pushing their heads backward The absence of proved displacements of the Queensland Divide does not disprove changes in areas that are geographically much older

University and Educational Intelligence.

BIRMINGHAM.—The degree of D.Sc. has been awarded to Martin Christopher Johnson for published papers on the adsorption of hydrogen and other molecular problems *in vacuo*, and Wilfred John Hickinbottom for numerous published papers in organic and physical chemistry and biochemistry, on carbohydrates, rearrangement of alkylanilines, acetone, butyl fermentation, and distillation of dilute solutions.

CAMBRIDGE.—The Director of the Solar Physics Observatory has, with the consent of the Vice-Chancellor, appointed Dr. R. O. Redman, of St. John's College, to be assistant director of the Solar Physics Observatory for five years from April 1 next.

Dr. C. P. Snow has been elected to a fellowship at Christ's College.

The Council of the Senate has issued a report on the regulations for the Botanic Garden. It is recommended that the Botanic Garden Syndicate shall consist of (*a*) the Vice-Chancellor, Master of Trinity College, the Provost of King's College, the Master of St. John's College, the Regius professor of physic, the professor of botany; (*b*) the present elective members; (*c*) four persons appointed by the Faculty Board of Biology "A"; (*d*) two persons appointed by Grace on the nomination of the Council of the Senate. It is recommended that the present Director shall be responsible for the management of the Garden under the Faculty Board of Biology "A". He shall give assistance to the professor of botany by teaching systematic botany in the Garden and in other ways. When the directorship falls vacant, the professor of botany shall either himself be director, or appoint as director, with the concurrence of the Faculty Board of Biology "A", a University teaching officer in the Department of Botany, the appointment to be made for a limited period, not exceeding five years. A director shall be eligible for reappointment.

A COURSE of six lectures, dealing with "Some Philosophical Aspects of Modern Industrial Society", is to be given by Prof. P. Sargant Florence at the British Institute of Philosophical Studies, University Hall, 14 Gordon Square, W.C.1, on Tuesdays at 5.45 P.M., beginning on Jan. 20. The lectures, which are free to members of the Institute, are open to the general public at a nominal fee. A syllabus of the course, and other particulars, can be obtained from the Director of Studies, British Institute of Philosophical Studies, University Hall, 14 Gordon Square, W.C.1.

THE International Federation of University Women has issued a report of its council meeting held at Prague last July. The Federation now comprises thirty-four national associations of members of the universities of nearly all the countries of Europe, of the United States of America (more than 500 branches), Canada, Australia, New Zealand, India, South Africa, and Mexico. The Prague meeting was signalised by the gift of £1000 by President Masaryk to the Federation's Travel and Research Fellowship fund, completing the endowment of the first of these fellowships. The Federation has issued a complete list of international fellowships available to graduate students, both men and women, wishing to work in foreign countries. It endeavours to promote exchanges of teachers, junior medical officers, museum curators, librarians, archivists, and lecturers. It also organises group travel tours arranged with reference to special professional or cultural interests. For the coming season, tours are being organised in England, Germany, Italy, and Norway. The headquarters are at Crosby Hall, Cheyne Walk, London, S.W.3.

ON Saturday, Jan. 3, the first national conference for advancing the cause of adult education by wireless was opened at the London School of Economics. The conference was composed of representatives of the Central Council for Broadcast Adult Education and the British Institute of Adult Education. Dr. Temple, Archbishop of York, in a letter regretting his absence, pointed out the great importance of group discussions. Such groups are undoubtedly a great asset, since they prevent, as Dr. Temple remarked, the mere reception and indiscriminate assimilation of the material broadcast. It is conceivable that any type of broadcast talk would probably defeat its own object if received without question by the listener. With child education, such a possibility is eliminated by the teacher, who may clarify, stress, or amplify points at his or her own discretion. In the case of adult education, this is naturally very difficult, and therefore the formation of study groups, which promote discussions, is to be encouraged. The growing influence of broadcasting on education, especially in the case of adults, is made evident by the formation of four hundred study groups up to the end of last year. This should encourage the B.B.C. to continue its efforts in wireless education.

Birthdays and Research Centres

Jan. 13, 1869.—Sir RICHARD PAGET, Bart.

I am at present studying the mouth gesture of the root words of modern English, a large proportion of which are found to be pantomimic. Thus, nearly all words beginning with STR have meanings connected with the tongue gesture which produces the STR-sound, namely, a stroking, streaking, or stretching from behind the teeth to near the back of the palate. Linguists might usefully compare the root words for gesturable ideas in the various language groups of the world from the point of view of mouth gesture.

On the experimental side there is a great opening for work with plasticine and rubber models to elucidate the methods of producing different qualities of tone in voice production. The musical experiment suggested on pp. 184-188 of "Human Speech" still awaits a practical trial by three expert players of the Swannee whistle.

Jan. 18, 1868.—Sir LEONARD ROGERS, C.I.E., F.R.S.

A forecast of the probable incidence of cholera, smallpox, and plague in India during 1930, based on the previous year's meteorology on the lines I had worked out, has proved remarkably correct. A similar forecast for 1931 will shortly appear.

A severe epidemic of leprosy in Nauru Island has been reduced by 40 per cent in three years by my plan of clearing up the cases by injections of hydnocarpates in the early stage, discovered by repeated examination of contacts; so the means of stamping out leprosy are now available.

The discovery I made in 1916-18 that the acid-fast bacilli of leprosy can be destroyed in the human tissues by hydnocarpates and morrhuates makes further work on these lines the most hopeful method of treating tuberculous disease. New preparations of hydnocarpus and cod liver oils are now being tested experimentally and clinically against tubercle.

Jan. 22, 1881.—Prof. J. W. HESLOP HARRISON, F.R.S., professor of botany and reader in genetics at Armstrong College, University of Durham.

My researches on the botanical side are mainly directed toward the elucidation of evolutionary problems in the genera *Rosa* and *Salix*. In the section Caninæ of the genus *Rosa*, reproduction, whilst

facultatively sexual, is mainly secured by apogamy or sporophytic budding Recently, however, cases have been detected in almost sterile crosses between *R spinosissima* and the Caninæ in which a true parthenogenesis occurs Offspring so produced is fully fertile and presents novel cytological features Strongly resembling *R spinosissima* and fitted for habitats of that species, such plants become a by no means negligible element of certain *R spinosissima* populations, which thus approach the condition of hybrid 'swarms' The problems presented by these populations are being attacked genetically, cytologically, and in the field

On the zoological side, I have found that the larvæ of the moth *Selenia bilunaria* respond readily to their environment in respect to pigmentation The inheritance (or otherwise) of such colour effects is being studied in crosses between alderwood and hawthorn hedge strains, as well as in others involving larvæ experimentally treated Simultaneously, work proceeds on the inheritance of bivoltinism induced in univoltine northern races of the same insect

Societies and Academies

LONDON

Geological Society, Dec 3 —**H Dewey** The Palæolithic deposits of the lower Thames valley Recent work near Swanscombe (Kent) has revealed some facts of interest with regard to the relationship of the Thames deposits to Palæolithic man The deposits of the 100 foot terrace in the old pit at Milton Street are still being extensively worked They are upwards of 30 feet thick, and are divisible into three beds of sandy gravel, lower, middle, and upper, separated one from the other by beds of marly loam, and they rest upon a clean cut surface, or 'shelf', of chalk and Thanet sand at a level of 88 feet above O D Correlation between the deposits at Milton Street with those at Ingress Vale is established —**P Tesch** The Riss glaciation in the south eastern parts of England The plains of western Germany and northern Holland and the North Sea basin were covered by the ice sheet of the Riss glaciation Short accounts of the fauna and flora of these beds are given in the paper A close conformity is shown to exist between the Dutch deposits and those of Norfolk The author does not agree with the late F W Harmer that the two ice-sheets of East Anglia mark two different glacial periods, but only re advances during one, the Rissian, glacial period

Royal Meteorological Society, Dec 17 —**J Glasspoole** Heavy falls of rain in short periods (two hours or less) The paper gives details of intense falls in 10, 15, 30, and 60 minutes as recorded in 7 years at 14 stations distributed over the British Isles This is a more detailed examination than has been carried out previously, thus, at Camden Square (London) 0 16 inch or more has fallen in 10 minutes on 22 occasions in 7 years, and on the average of the 14 stations 0 80 inch or more has occurred in an hour once in 7 years Details are given of the heaviest, second heaviest, and third heaviest rains in specified times at each station —**M T Spence** The factors affecting visibility at Valentia Observatory This paper analyses by means of frequency tables the relationship at Valentia between visibility and (*a*) cumulus cloud, (*b*) wind force, (*c*) humidity Visibility is better when there is cumulus cloud in the sky than when there is not; it deteriorates with increasing wind force, and improves with decreasing relative humidity down to comparatively low values of humidity The relationship between visibility and cumulus cloud is regarded as showing that visibility at Valentia is generally better in air of polar origin than in air of equatorial origin The deterioration of visibility with increasing wind force is not due to the stronger winds being land winds or to their being more humid than the lighter winds it is concluded, therefore, that sea spray, the amount of which varies with wind force, gives rise to the greater obscurity with strong winds Improving visibility with drier air at comparatively low values of relative humidity may be associated with slow evaporation from the hygroscopic nuclei

DUBLIN

Royal Dublin Society, Nov 25 —**J Joly** The application of gamma radiation to deep-seated tumours (2) An apparatus was exhibited (made in accordance with a design recently published in the Society's *Scientific Proceedings*) whereby two tubular applicators, each yielding a beam of unscreened gamma rays from a suitable radium or radon source, are carried round a template in such a way that the beams intersect at any given distance, and the point of intersection traces out a path determined by the shape of the template The apparatus may be strapped in position on the patient's body and fitted with suitable templates so that all parts of a deep seated tumour may be subjected in turn to the focusing action of the convergent beams A small electric motor with suitable reduction gearing moves the tubes slowly round, or use might be made of the patient's respiratory movements by means of an inextensible belt lined with a light rubber tube lightly distended with air, the variations in pressure of which would provide the requisite power —**H H Dixon** and **G Joly Dixon** The exudation of water from the leaf tips of *Colocasia antiquorum* Schott The liquid issuing from the leaf tips of *Colocasia antiquorum* is practically pure water Hence it has been concluded that osmotic action is not responsible for its expulsion Flood showed by histological and experimental methods that the stream is not due to glandular action The authors demonstrate by simple working models that a continuous stream of pure water may be forced upwards by the osmotic pressure developed by solutions in the lower parts of the plant, and suggest that the pure water emerging is derived from these solutions, which have been depleted of their solutes, as they rise through the capillaries of the conducting tracts —**H H Poole** A modified form of radon capillary apparatus The apparatus in use in the Society's laboratory for supplying radon tubes for therapeutic use has been further modified so as to combine the reliability of yield (90 per cent), obtainable with the original apparatus, with the ease of working characteristic of the modified form introduced two years ago.

WASHINGTON, D C.

National Academy of Sciences, (*Proc.*, vol 16 No 9, Sept 15) —**Paul S. Galtsoff**. The rôle of chemical stimulation in the spawning reactions of *Ostrea virginica* and *Ostrea gigas* Females are induced to spawn by the presence of sperm; there is a lag suggesting that the active principle, which is insoluble, is absorbed through the digestive tract Male oysters are stimulated by egg suspensions when there is no lag, and also by sperm Males respond more readily to rise of temperature One male having spawned stimulates its neighbours both male and female, and so spawning may spread over a whole bank —**Henry Borsook** and **Howard M Winegarden** On the free energy of glucose and of tripalmitin The ratio of the theoretical maximum work obtainable by oxidation under physiological conditions to the total energy of the change i

nearly the same for these substances It seems that fat is burned as such in the provision of energy for muscular work, or the energy released in the hypothetical conversion of fat to carbohydrate is not dissipated as heat but used as work—Wilder D Bancroft and George H. Richter · Claude Bernard's theory of narcosis. Bernard concluded that reversible coagulation of colloids of the sensory nerves produces or accompanies anaesthesia Proteins are important in anaphylactic shock. Assuming that there is increased irritability as the nerve colloids approach instability and the beginning of reversible coagulation, it should be possible to observe, with increasing amounts of anaesthetic, first increased irritability, then anaesthesia, finally death if coagulation becomes irreversible Thus, strychnine may be a stimulant in small doses and cause death in large doses, in an intermediate range of concentrations it is an anaesthetic Similarly, yeast cells narcotised with alcohol show coagulation which can be reversed by removing the alcohol, when the cells recover Thus the difference between an anaesthetic like ether and a habit-forming drug like morphine is that the former is rapidly eliminated whereas the latter or its products is retained, keeping the system irritable Nitrous oxide acts indirectly, it interferes with oxygen metabolism, giving rise to acid products which cause flocculation—Linus Pauling The structure of the chlorites The structure deduced leads to the general chemical formula $X_mY_4O_{10}(OH)_8$, with $4 \leq m \leq 6$—Richard C Tolman Discussion of various treatments which have been given to the non static line element for the universe—Einar Hille and J D Tamarkin On the summability of Fourier series third note—Francis F Lucas The architecture of living cells—recent advances in methods of biological research—optical sectioning with the ultra-violet microscope The ultra-microscope as developed for metallography has been applied to photograph the structure at different planes within a single cell or group of cells The sensitivity of the fine adjustment of the microscope has been increased so that a movement of a quarter of micron is possible and series of photographs at these intervals are taken in the light of a cadmium spark With a transparent specimen, detail above or below the exact focal plane does not interfere with the image, so a series of 'optical sections' is obtained Since organic specimens are differentiated in structure by their selective absorption of ultra-violet light, staining is not usually necessary Some striking photo micrographs are reproduced in the paper—L S Kennison A fundamental theorem of one parameter continuous groups of projective functional transformations—Harry Merrill Gehman A special type of upper semi-continuous collection—R D Carmichael On expansions of arithmetical functions—A D Michael and L S Kennison Quadratic functional forms in a composite range—G C Evans and R N Haskell The mixed problem for Laplace's equation in the plane discontinuous boundary values

The Worth of Science

AT the nineteenth annual Conference of Educational Associations, held at University College, London, the president, Sir Richard Gregory, selected as the subject of his inaugural address "The Worth of Science" The address was no mere *catalogue raisonné* of the contributions of science to material progress and human comfort, no mere *addition* of the economic value of scientific discoveries In terms of billion and bullion only, no such evaluation is possible, for the liberation of life and intellect brought about by the work of the pioneers of scientific discovery is beyond price Galileo's classic words, *Eppur si muove*, helped to establish man's right "to think for himself in the realm of natural knowledge and to place personal observation above metaphysical and philosophical speculation and dogmatic assertion" Teachers may well be reminded of this debt to science, for without this spirit of freedom, "bequeathed from bleeding sire to son", their work would be degraded and the punishment reserved for them by Lucian, to sell kippers in the lower world, would be well deserved

Science has suffered some hard buffetings, especially in the United States, because the doctrine of evolution is supposed to be concerned with the obvious resemblances between men and monkeys and to envisage human progress in terms of "Nature, red in tooth and claw" But, as Sir Richard Gregory pointed out, evolution embodies the idea of social ethics, making the welfare of the community the essential purpose of the life of the individual If we study Nature we shall find abundant examples of ruthless cruelty, 'void and empty of every drachm of mercy", but we shall also find most beautiful examples of patience, co operation, self-sacrifice, and other virtues of which the human race cannot claim the patent

Finally, if it is fair to attempt such rapid summary of this admirable address, Sir Richard impressed the great lesson that science must not be blamed for the use to which its riches, its *cornucopia*, its bulging corn bins, are applied by the human race For more than a century chlorine had served a useful purpose as a disinfectant and a bleaching agent, before its use in warfare provided one of the greatest tragedies of the War If science offers to mankind a new earth, the question whether the new earth is better than the old depends on human will, on human judgment Science enables us to speak by wireless across the estranging ocean, but when the ethereal link is joined, have we anything

worth saying? Thomas Love Peacock remarks that civilised man admits he is unhappy anywhere and then congratulates himself on devising a machine which will transport him rapidly from one place where he is unhappy to another where he is not less unhappy

The wheel of life takes a full turn and, like the alarum clock which awakes us to another day's labour, science awakes us at intervals to a new world Galileo escaped with the comfortable punishment of being immured in his own study, but some of his contemporaries might have gone to the stake for the simple proposition that the earth goes round the sun After some centuries of intense study and research, the universe is still mysterious, more mysterious than to Galileo and his inquisitors, and if Einstein, Eddington, or Jeans were asked the simple question, "Does the earth go round the sun?" the answer, we suppose, would not be a plain yes or no Whatever that answer may be, however incomprehensible the mathematics used for its demonstration, there would be no *auto da fe*, no question of martyrdom *Eppur si muove*—though the modern world is able on occasion to devise subtle forms of persecution for the man of science

The impossibility of reaching finality is part of the lure of science, and, in a sense, of the "Worth of Science" Turning to medicine, Sir Richard Gregory said, with perhaps a *soupçon* of superiority, "When a savage is ill, he naturally attributes his sufferings to some enemy within him, and to witchcraft putting the enemy there" As regards certain diseases, that is apparently also the present view Dr H P Newsholme in his essay on certain aspects of encephalitis lethargica, entitled "Health, Disease, and Integration", attributes this disease in man to a lack of balance "within him" Owing possibly to some evil thought or memory, to some repression, the body cells begin to behave in a peculiar way Encephalitis lethargica has secured a new victim We must not exclude the possibility of learning from the untutored savage, though he may not have the hebdomadal privilege of reading NATURE The wise men of the east have wrested secrets from the book of Nature by the simple method of doing nothing, secrets which *Homo sapiens* of the west would not have discovered by fevered activity

Who shall point the way to the birthplace of Christ? Sir Richard Gregory did not evade this aspect of his subject He properly reminded us of Lessing's dilemma, the choice between truth and the impulse towards truth Leave the reality of absolute truth to its Creator and accept the impulse towards truth as the guide of life, and we shall be as happy as George Meredith's costermonger's donkey, going blithely along at a trot, merry in harness while we have to serve Happy—and humble too Is it not one of the greatest assets in the balance-sheet of science that it teaches those lessons of true humility which helped and comforted Bunyan's pilgrim on his weary progress?—

He that is humble ever shall
Have God to be his guide

Man and his Universe

Man and his Universe By John Langdon Davies Pp xviii + 334 + 14 plates (London Harper and Bros, 1930) 16s net

THE author of this book has set forth in non technical language a series of pictures of man and the universe as seen by our primitive ancestors, by men of the Middle Ages, and by those who lived during the Renaissance, the Darwinian epoch, at the end of the nineteenth century, and finally in 1930 We may say at once that, when reconciled to the occasionally journalistic style, the reader can study the book with profit and interest We may criticise points of historical detail and feel unconvinced by some of the lessons the author draws from modern science, but we must admit that on the whole the work is well done, and that at all events it makes a good story

Mr Langdon Davies's main position is that science from one aspect is poetry (concealed by text books) and from another a search for God, in the course of which a series of new gods are discovered To explain the influence of science on religion, Mr Langdon-Davies quotes W K Clifford "The character of the emotion with which men contemplate the world, the temper in which they stand in the presence of the immensities and the eternities, must depend first of all on what they think the world is"

Mr Langdon-Davies is quite right in holding that, to understand our present outlook on life we must know something not only of savage superstitions and modern science, but something also of the thought of the intervening two thousand years He overlooks the earliest part of this time —the age of the pre-Aristotelian Greek philosophers, and also that of the first Christian synthesis of knowledge, which was predominantly Platonic and Augustinian He assumes that the influence of Aristotle was supreme throughout the

Dark and Middle Ages, and does not adequately appreciate the change in thought produced by the re-discovery of Aristotle's works by Europe in the thirteenth century Hence his medieval picture is true only of the time of the later centuries, when the characteristic thought of the Middle Ages was drawing towards its close, but of that period he gives a fair representation

The later Schoolmen, and especially Albertus Magnus and Thomas Aquinas, put together a new synthesis of knowledge, in which the science of Aristotle was combined with Christian dogma in a rational and consistent whole Hence, at the Renaissance, to attack Aristotle was to attack the Catholic faith, and innovators had to walk warily The Scholastic scheme regarded the earth as the centre and man as the meaning of creation, and the apprehension of God by the exercise of reason as the object of man The sublunary world was imperfect and subject to change, but the celestial spheres were faultless and unchangeable, spheres indeed because the sphere is the 'perfect' form—here again, let us note, is a survival of one of Plato's ideas

Ptolemy himself looked on his system of astronomy only as a mathematical exploration of the facts, and St Thomas regarded the geocentric view of the universe as a hypothesis, but less clear-sighted men took it as indubitable reality, both from the evidence of the senses and from Christian dogma Hence the Copernican system, when understood as a representation of fact, involved a true revolution in thought Mr Langdon Davies points out that Copernicus and Kepler were searching for mathematical harmonies and simplifications, but he misses the interesting connexion between their views and the Platonic and Pythagorean background, which survived beneath the predominant Aristotelianism of their day

Following mainly in the footsteps of Prof Burtt, Mr Langdon-Davies draws a contrast between the world of Aristotle and Aquinas and the world as it appeared when Galileo and Newton had done their work The first was a world essentially as it appears to the senses and was interpreted in human terms, a world of colour and form, of truth, beauty, and goodness—or perhaps their opposites In the second, the sole reality of the universe was matter in motion, regardless of human values, desires, or welfare Although Newton and his immediate followers still saw God in Nature, in the eighteenth century the philosophy developed from Newtonian science led through mechanism to materialism In the nineteenth, Lavoisier showed that matter was indestructible and unchangeable in amount, Dalton put the old atomic theory into modern guise, and Joule established the principle of the conservation of energy Finally Darwin and Wallace seemed to have brought man himself under the iron sway of 'natural law'

There seemed little more to learn and nothing much to do The whole of Nature appeared to point to determinism But, while nineteenth century science was reaching its climax, the new renaissance was coming into being Matter, which the plain man thought he understood as inert, solid lumps, was resolved into electric charges, sparsely scattered through the vast empty spaces of atoms, and radioactivity showed that some atoms at least are not eternal Quantum mechanics destroyed the idea of continuity, and the principle of uncertainty within the atom threw doubt on determinism as an ultimate character of Nature Finally, the principle of relativity showed that many things thought to be absolute depend on circumstances

Mr Langdon Davies has as much right as the rest of us to draw what conclusions in philosophy, religion, and morality seem to him to follow from these recent revelations The old orthodoxy and nineteenth century materialism are alike dead to him, and the chief consequences of the modern outlook on life are the removal of the sense of fear —fear of most of the evils of this world and of any other—and the passing away of the longing for immortality and of other age long desires which to him seem to be beyond our reach, if not meaningless Mr Langdon Davies will not expect us all to see eye to eye with him, but we can at least agree that the change produced in philosophic thought by the new scientific renaissance is and must be profound W C D D W

Science and Armaments

The Problem of the Twentieth Century a Study in International Relationships By David Davies Pp xvii + 795 (London Ernest Benn, Ltd, 1930) 21*s* net

MAJOR DAVID DAVIES has given us a very fine and weighty book It is an admirable illustration of the power of one definite idea, strongly held, to organise a great mass of knowledge and make it all subserve one supreme point This point to Major Davies is the need of an international police force to secure the obedience of the world to the dictates of the League of Nations It is not a new point, of course The French put it forward when the League was first started, and ever since

the critics of the League have been saying, "What can the League do to enforce its will, when it is faced by a recalcitrant Power, stronger than those, like Greece, Bulgaria, Jugoslavia, or Albania, with whom it has hitherto dealt? When a serious crisis arrives, will it not be defied and the world plunged again into anarchy and war, worse, no doubt, than we suffered in 1914–18?" It is because Major David Davies has felt so deeply the force of this argument and the horror of the prospect that he has been moved to write this eloquent and persuasive book.

The author assumes all the dangers of the present situation at their worst, and sets to work to plan a complete and watertight scheme to meet them. For, granting his premise and granting the feasibility of winning the assent of the Powers to it, nothing could be better thought out or fitted together than what he has given us. It is well worth the somewhat considerable time needed for reading nearly 800 large pages to see how he presses all the resources of literature and knowledge into the service of his cause. History in abundance, politics, statistics, even poetry, find a place. But how many people will be found to read the book, good as it is, or still less, to buy it? Every sincere sympathiser—and it may be predicted that anyone who gets through will sympathise—will join with this reviewer in an earnest wish that the author himself, or someone for him, will issue an abridged edition in a quarter of the volume, at a tenth of the price.

Major Davies's plan is simple and attractive. It has the great merit that every part of it has some foundation, either in the actual constitution of the world or of the League, or in the recent achievements of science and human thought. In the first place, there is to be what we might call an international General Staff, which would be recruited, as the Secretariat of the League now is, from all the signatory nations according to their weight. The principle of the 'barème', which is followed in assessing the contribution of the States Members of the League, is often invoked by Major Davies in this and other connexions. As the force is to be essentially of a police nature in regard to its duties, its chief would be called the High Constable, and this post might at first be held by a Frenchman, but only for a short period of years. Then there would be other constables at the head of the different sections—mechanical warfare, navy, air, and gas—into which the force would naturally be divided. But the central permanent staff would be but small, and arrangements would have to be made for speedily enlarging it at times of crisis by drafting into it the national quotas which all States members would train in their own countries, and which would be under their own control except when drafted into the international force.

In this matter Major Davies appears to us to show best his good judgment and his sense both of compromise and of the politically possible. It should be, he thinks, in the discretion of the national governments whether their quota should be sent for the particular service; but he looks to the growth of the community spirit, to the fact that the expenses would be borne by the community and that those who need protection themselves would be inclined to help in the protection of others, to secure that sufficient forces were always available to repress the aggressive or disturbing Power. But, in order to make concentration as quick and easy as possible, it is suggested that besides the headquarters, which might well be placed in Palestine, there should be unit bases of the international force all over the world. Strategic points and centres of existing international contact would be carefully chosen, such as Suez, Gibraltar, Panama, and it might always be made worth while for any Power, say the Turks in Constantinople, to allow a part of their territory to be used for this purpose, either by a substantial payment or by concessions elsewhere. Because—and this is one of the strongest two arguments in Major Davies's favour—he can count confidently on so large a saving in the general expenditure on armaments, that the world could afford to do well what he regards as the most necessary part of the whole. For it will be understood that it is as a step towards general disarmament that the scheme is planned. If the nations could gain a sense of security from the proposed international force, they would be content to let their domestic forces be cut down to a point of which the position of Germany under the Treaty of Versailles is the standing model.

We have left to the last what is perhaps the strongest, certainly the most impressive, of Major David Davies's arguments. It is the side which links up his case with science. He shows how the War was a turning point in the evolution of armaments, due to science; and that the process has gone on with increasing rapidity ever since. The air and gas are the two outstanding cases. One modern fighting aeroplane, we are told, could ward off and possibly put out of action a thousand aeroplanes of the pre-War or early War type; and the chemists go on making more and more deadly gases, in spite of several international undertak-

ings not to use any This appalling fact gives the author his most effective argument "Hand over", he says, "all those recent and future applications of science to warfare to your new international police force, and let domestic armies be content with pre-War armaments" Would that the nations would agree!

One feels at the end of this most suggestive book that it would prove as easy to persuade the world to turn all its swords into ploughshares as to adopt Major Davies's suggestions Meanwhile, let us labour incessantly to improve the existing machinery of the League and to carry out our existing obligations In this we shall have his support, no doubt, as he has our sympathy for his ingenious and further reaching scheme

F S MARVIN

Bacteriology

Medical Research Council A System of Bacteriology in relation to Medicine Vol 1 By F W Andrewes, J A Arkwright, J E Barnard, C H Browning, W Bulloch, H Chick, A D Gardner, A Harden, H McCombie, J W McLeod, E K Rideal, R St John Brooks, A Slator, H G Thornton Pp 374 + 18 plates (London H M Stationery Office, 1930) 21s net

IN Chapter I—"History of Bacteriology"—Prof Bulloch leads us from the ancient theories of epidemic disease and the discoveries of Leeuwenhoeck, through the work on spontaneous generation and many of the fascinating, though imperfect and often erroneous, results of some of the early investigators up to the brilliant work of Cohn, Pasteur, and Koch We are glad to read the high tribute given to the work of Cohn, who has been largely overshadowed by the man whom he discovered—Robert Koch The work of Pasteur, Koch, and many other brilliant investigators is given very fully, and the author finishes off with the history of the immunity doctrines Our only regret, in reading this chapter, is that much more space has not been given to Prof Bulloch We feel sure that this article will be read and re read many times by all ardent bacteriologists, not merely because it contains such a mass of interesting particulars, but also because of the style in which it has been written The illustrations are of supreme interest, and, might we add, we are glad to see in this volume many illustrations which are regretfully absent from the volumes which have been issued

The short chapter on morphology will prove of value, though we think the more bacteria and bacterial variation is studied, the less importance will be attached to morphology

In Chapter III Rideal deals with the physics of the bacterial cell and McCombie with bacterial pigments, while Chapter IV is concerned with growth and reproduction of bacteria A great deal of work has been summarised in these chapters, but the most interesting, and we think the most valuable parts, are those on cell division, colony formation, and spore formation, by Dr Gardner, and on the life cycle of bacteria, by Thornton The work of these authors makes us go back and re-read with greater interest and much more appreciation the work of the late Prof Löhnis

Chapter V, on the theory of disinfection, is of great interest, and quite well written There are many suggestive thoughts in it, but we consider its practical value somewhat limited We would have expected some information as to the action of common disinfectants on various types of bacteria In the section by C H Browning, which is very good, the selective action of the various dyes is emphasised, but this selective action is almost as well marked with the antiseptics in common use, so much so that the usual Rideal-Walker test for antiseptics is regarded by us as of very little value In a 'System' of this importance, so many omissions of points of practical value—unless a further chapter on disinfection is to appear in subsequent volumes—renders this chapter a very imperfect one

Chapter VI, on the metabolism of bacteria, by Arthur Harden, is such as one would expct from so distinguished a bio chemist It is very readable and should prove of considerable value to all scientific bacteriologists

Prof McLeod's work on the reducing action of bacteria, the production of peroxide and its bearing on anaerobiosis, has already taken a prominent place in bacteriological literature We expected in the chapter on bacterial respiration to have a paper somewhat unusual in character, of scientific interest and of practical value We have not been disappointed It is a chapter well worth careful study and thought

In Chapter VIII Sir Frederick Andrewes has undertaken an extremely difficult task Classification is needed, and to bring order out of the present chaos is a worthy ambition We have in this chapter a very accurate account of the various attempts, the successes, and the failures, and then we are given the criteria for classification—the morphology, cultural characters, etc The author concludes that "in any given case it is the sum of

the various characters which counts" After we have read the chapter, we feel that though the principles have been carefully demonstrated, we are to day no nearer an accepted and international classification or nomenclature than we were years ago We would like to have said more about "the marriage between Northern names and Latin terminations", but perhaps the polished language of the author is a better protest against these 'barbarisms' than our more vigorous language would have been

Chapter ix deals with variation In this chapter there is a great deal of new work, much of it based on the researches of the author The material is of very great importance, and the facts are all well put The general literature on this subject is very confusing, and we welcome the attempt—and we think the successful attempt—to make it clear The chapter requires careful and thoughtful reading, but it will well repay the time and labour spent on it

Taking this volume as a whole, it is the most interesting one yet issued, and, in itself, will give this 'System' a very high place in bacteriological literature J M BEATTIE

Biological Control of the Coconut Moth

The Coconut Moth in Fiji a History of its Control by means of Parasites By Dr J D Tothill, assisted by T H C Taylor and R W Paine Published for the Government of Fiji Pp vii + 269 (London The Imperial Bureau of Entomology, 1930) 31*s* 6*d* net

THIS sumptuously produced volume is in reality a detailed account of a single experiment in applied entomology It is concerned with the biological control of a species of moth the larva of which, in attacking the coconut palms of Fiji, threatened the copra industry of those islands with disaster The insect in question, *Levuana iridescens*, belongs to the family Zygænidæ and, so far as is known, is confined to Fiji Its larvæ, by destroying the foliage of the coconut, converted what were originally waving green fronds into remnants of miserable lifeless grey Since the insect proved to be free from parasitic enemies, this fact in itself suggested that its original home may be in some land other than Fiji It also appeared probable that the introduction, under favourable conditions, of some effective insect enemy might go a long way towards solving the problem of its control The present volume is a record of how this theory was translated into practice

Since a search among the Pacific islands for *Levuana* in its native home, where it would most likely be subject to attack by parasites, proved fruitless, recourse had to be made to allied coconut pests Insects of the family Zygænidæ are rarely destructive, but the species *Artona catoxantha* is known to attack coconuts in Malaysia and Java It proved, furthermore, to be subject to attack by the Tachinid fly *Ptychomyia remota* Since *Artona* and *Levuana* are closely related, it appeared probable that a parasite of the former genus would find the *Levuana* an acceptable host The campaign hinged on this possibility and, after considerable difficulties, the Tachinid fly was eventually introduced into Fiji The success of the experiment was remarkable six months after its introduction, the fly had spread throughout the areas of Fiji affected by the *Levuana*, and many of the outbreaks had subsided entirely owing to the destructive effects of this parasite upon the caterpillars of the moth There has, to-day, been no outbreak of the pest for more than three years, and the copra industry of Fiji has been extricated from an awkward predicament by this fortunate biological experiment

The history of the campaign is described in detail in this volume the structure and life-history of the moth are elaborately dealt with and the parasitic *Ptychomyia* is similarly discussed Allied Zygænid moths and their natural control also come in for treatment, and there is a wealth of text-figures and beautifully executed coloured and half-tone plates appended The whole volume thus serves as a detailed permanent record of an experiment of equal importance to those achieved in Hawaii and elsewhere No similar biological triumph has so far been placed upon record in so complete and elaborate a form The high price of the volume may militate against its rapid circulation, but all whose business is concerned with pest control will need to add it to their bookshelves It should prove a valuable propagandist source in that it will focus attention upon the possibilities of biological control—when it is applied intelligently to problems amenable to this method of solution

A number of entomologists, administrators, and others have played their part in the campaign recorded To each of these we tender our sincere congratulations upon an achievement that should rank high in the annals of applied entomology The Imperial Bureau of Entomology, which published the volume on behalf of the Fiji Government also deserves commendation for the faultless style in which it has been produced A D IMMS

Our Bookshelf.

Lord Balfour in his Relation to Science By Lord Rayleigh Pp viii + 46 (Cambridge At the University Press, 1930) 2*s* 6*d* net

FOLLOWING the death of the Earl of Balfour, F R S , Chancellor of the University of Cambridge, which occurred on Mar 19 last, an obituary notice by his kinsman, Lord Rayleigh, was published in the *Proceedings of the Royal Society* This memoir was limited to an account of Lord Balfour's early history and mental development, his scientific and philosophical thought, and his administrative work for scientific, industrial, and medical research Quite justifiably it was soon realised that, beyond strictly scientific circles, there was an interested public desirous of knowing about those very matters detailed therein, their kind and substance Accordingly, the memoir has been republished, with a photograph as frontispiece

In all probability the public referred to would have welcomed more about this many-sided personality in fields of knowledge and inquiry which embraced science The earlier part of the memoir recalls Balfour's upbringing, and the springs of scientific interests which welled up in the family brotherhood and sisterhood and immediate connexions As regards the latter, Lord Salisbury, sometime Prime Minister, was Balfour's uncle, Lord Rayleigh (father of the writer of the memoir), his brother-in-law We are told that throughout his life Balfour had the highest admiration for Darwin, "because", he said, "he was not a partisan—he really wanted to find out the truth—an attitude of mind seldom found among men of science, and never among theologians" Rather contrariwise, an extract from Lady Rayleigh's journal, June 16, 1892, records that "Paderewski was at the Royal Society soirée last night, and in discussing it Arthur remarked of the scientific guests, 'They are the people who are changing the world and they don't know it Politicians are but the fly on the wheel—the men of science are the motive power'"

Throughout this study no passing allusion is made to Lord Kelvin, yet contact with Balfour must have been close and cordial, and fraught with inherent interest He was, in fact, president of the Royal Society at the date of the soiree mentioned above

State of Arkansas Arkansas Geological Survey Bulletin 3 *Geology of the Arkansas Paleozoic Area, with especial reference to Oil and Gas Possibilities* By Carey Croneis Pp xx + 457 + 45 plates (Little Rock, Ark Arkansas Geological Survey, 1930)

THE area covered by this work is some 25,000 square miles in the central, northern, western, and north western parts of the State of Arkansas, constituting the highlands and embracing the well-known physiographic elements the Ozark Plateau, the Arkansas River Valley, and the Ouachita Mountains The volume is of interest to geologists generally because of the good account of the different palæozoic faunas given, an account enhanced in value by the excellent illustrations of the characteristic fossils In fact, the illustrations as a whole are such a conspicuous feature that they may almost be said to make the book Certainly, some of them depicting field-features would adorn many a well recommended text book of physical geology, and it is a pity that they are comparatively lost in a State survey memoir

With regard to oil and gas possibilities, the Ouachita Province is regarded as unfavourable, the Arkansas Valley implies for the most part dry gas resources, and the southern part of the Ozark highland has a slight chance of oil production There is a sidelight on the applicability of the carbon ratio theory in connexion with the gas prospects, some of the ratios of the Carboniferous coals are so high as eighty eight, which should rule out any possible existence of gas fields, these ratios, in point of fact, are without significance, since some of the largest producing gas fields are located in such terrain

This is a readable memoir It gives a clear impression of the pure and economic geology (in so far as oil and gas are concerned) of a vastly interesting region, and in style and presentation breaks away from the more monotonous conventions of the national survey There are two maps included, both tectonic, one depicting structural axes of the Arkansas Valley and Ozark Provinces, the other, axes of the Ouachita Mountain Province

H B M

Sedimentary Petrography with Special Reference to Petrographic Methods of Correlation of Strata and to Subsurface Oil Geology By Henry B Milner Second (revised and complete) edition Pp xxi + 514 + 40 plates (London Thomas Murby and Co , New York D Van Nostrand Co , 1929) 21*s* net

MILNER'S "Sedimentary Petrography" is essentially a laboratory manual and text-book It incorporates two previously published works by the same author—"An Introduction to Sedimentary Petrography" and "Supplement to an Introduction to Sedimentary Petrography"

In the new volume the author's aim has been to provide a comprehensive text-book of the petrology of all types of sediments, consolidated as well as incoherent Not only, therefore, is the text of the earlier volumes amplified and brought up-to date, but also much entirely new matter has been added Chief among this is a lengthy chapter on the petrography of the consolidated sediments, that is, limestones, shales, etc , as opposed to loose sands In another new chapter the author discusses at some length the desirability of the employment in the study of soils of the methods of examination of sedimentary rocks dealt with earlier in the text

The whole bias of the book is admittedly towards the examination of sedimentary rocks by study of their 'heavy residue' content, with emphasis on the economic applications of the results obtainable Commendable features are the numerous diagrams and plates, and the large

number of references in the text to original papers There is also an extensive bibliography

The practical study of sedimentary rocks has been much to the fore in recent years To all interested, whether from a scientific point of view, as oilfield geologists, or as soil mineralogists, this manual should prove invaluable

Production Conditions, Organisation and Results of Czechoslovak Farming Edited by Dr Vladislav Brdlík Part II Pp 242 + 79 (Prague State Agricultural Institute, 1930) 24*s*

AN elaboration of statistical material touching the production and yield conditions in Czechoslovakian agriculture is set forth in this volume The material is based on returns from 1652 farms for the years 1909–1913, and contains, on one hand, deductions from the statistical material published in Part I with comparisons from a territorial point of view, and on the other hand, a critical consideration of the data from the point of view of representative investigations The question brings into relief the changes in the organisation of farms and the results of their workings in the case of transition from the intensive and highly developed western methods to the extensive system as now practised in Czechoslovakia The deductions arrived at from the various points of view form a basis for measures of practical and economic policy (for example, customs, finance) and for scientific purposes, and so on The published material also has a historical significance, for it shows farming conditions as they existed before the great changes produced by the War The data, as worked up, provide a basis for various economic calculations, as they represent stabilised and normal relations both in regard to prices and methods of farming, and the method of presentation makes it possible to use the material in the case of changing price conditions It is claimed that this published statistical material will remain a basic and firm starting-point for the study of what is translated as the " dynamic economic phenomena"

For convenience of reference the critical examination of the data by Dr Stanislav Kohn is given in French and German as well as Czech, similar treatment being given to the introduction, chapter headings, and certain tables

Chinese Civilization By Prof Marcel Granet Translated by Kathleen E Innes and Mabel R Brailsford (The History of Civilization Series) Pp xxiii + 444 + 12 plates (London Kegan Paul and Co , Ltd , New York Alfred A Knopf, 1930) 25*s* net

DR GRANET's study of Chinese civilisation ranges from the beginnings as set forth in the traditional account of the Tsu-King down to the end of the second Han dynasty in the early years of the third century A D It falls into two parts In the first the political history is briefly surveyed In the second the constitution and development of Chinese society is reconstructed M Granet deals critically with the traditional history and shows it to be an ideal projected into the past by antiquarian reconstruction and remodelling of the materials Up to the present the auxiliary studies of ethnology and archæology have thrown little light on the problems of tradition, and M Granet constantly emphasises the need for excavation At the same time, he is prepared to put it forward as a working hypothesis that Chinese civilisation is to be explained by the contact of two principal civilisations, one a civilisation of terraces and millet, and the other a civilisation of rice and the low lying plains M Shirokogorov's investigations of the physical anthropology of Northern China would appear to support this view

In his second part, in dealing with Chinese society M Granet accepts tradition, but interprets it by a correlation with the evidence of the historic periods This makes possible a reconstruction beginning with the initial organisation among the peasant families and rural communities of the plains, passing on to the foundation of the chieftainships and the seignoral towns, and ending with the state of society at the beginning of the empire Here M Granet's work is a brilliant piece of interpretation

Birth Control on Trial By Lella Secor Florence Pp 160 (London George Allen and Unwin, Ltd , 1930) 5*s* net

THE enthusiastic claims of the contraceptive literature of a few years ago have now given way to a general impression that there is no satisfactory method of preventing pregnancy This is confirmed by an investigation undertaken by Mrs L S Florence at the Cambridge Birth Control Clinic, and now published under the title of " Birth Control on Trial " Her conclusion that such methods as can be recommended are too complicated and unreliable is fully justified Every doctor sees occasional patients whom he must warn to avoid pregnancy, and to such warning there ought to be added some instruction concerning methods There is obviously a demand for research into this subject, which can only be undertaken by the medical profession The book is not intended to hold a brief for the ethics of birth control, but some of the case-histories it contains are sufficiently tragic to shake the convictions of the most confirmed opponent of contraception

General Practice (Some further Experiences) By Dr Ernest Ward Pp iv + 108 (London John Bale, Sons and Danielsson, Ltd , 1930) 3*s* 6*d* net

DR ERNEST WARD's second book on the joys and troubles of general practice is as entertaining as his former " Medical Adventure ", in which were described clinical, obstetric, and pathological experiences The present volume is devoted to the other side of a practitioner's life, and covers a wide range of subjects, from where and how to secure a practice to when and whom to marry The chapters on the arrangement of the day's work, and the attitude of the doctor to his patients, his colleagues, and unorthodox treatment, are particularly good The author disclaims any intention of giving advice, but every page contains the equivalent of years of experience The book is sure to be of interest to every medical man

Stellar Structure

IN NATURE of Jan 3, Prof Milne writes that my theory of stellar structure accounts for the existence of giant, dwarf, and white dwarf stars, " only at the cost of *ad hoc* hypotheses quite outside physics It assumes stars to contain atoms of atomic weight higher than that observed on earth, and it assumes them to be relentlessly disappearing in the form of radiation, it appeals to discontinuous changes of state consequent on successive ionisations, for which there is little warrant "

This seems to me a mass of highly concentrated inaccuracy My actual hypotheses are that the stars we observe in the sky must be stable and need not be gaseous, it seems odd to describe these as " *ad hoc* hypotheses quite outside physics " What Milne describes as " assumptions " are inferences after the main results have been obtained After the Russell diagram has been obtained an atomic number of 95 seems to give the *best* fit with observation, but I could have " assumed " a far lower number and obtained quite a *good* fit Incidentally, no other theory gives any fit at all—or even anything to fit The appeal " to discontinuous changes of state " appears to be a highly coloured description of the fact that I find that bands of stability and instability alternate

I find it hard to believe that other astronomers understand my theory as little as does Prof Milne If they do, he is no doubt right in saying that the majority do not accept it

I am not writing to challenge Milne's inaccuracies so much as to ask whether his new theory must not ultimately prove identical with my own theory, which " the majority of astronomers do not accept " We start out on the same road, by not seeing eye to eye with Sir Arthur Eddington Milne's recent discoveries—that mass and luminosity are independent, that the mass luminosity relation is a happy (or unhappy) accident, etc —are merely old familiar landmarks on a road which I travelled and described fully in NATURE and *Mon Not R A S* more than ten years ago

Milne and I part company on the question of stellar boundary conditions The classical Emden solution starts with a finite density at the star's centre and integrates outwards Eddington, and then I, followed Emden in thinking that Nature was bound to look after the boundary conditions somehow or other Then I noticed (" Astronomy and Cosmogony ", §§ 80, 81) that what appears to be a single solution in a star's interior, spreads out into a whole tassel near the photosphere, it proves to be merely an asymptote to a whole family of solutions which correspond to different boundary conditions This shows that any boundary condition can be satisfied, so that " the influence of the special conditions which prevail at the surface soon disappears as we pass inwards into the star " (l c § 80)

This fundamental point can be illustrated by a simple model suggested by Milne (*M N*, **90**, p 53) Represent a star by a sphere of copper s with a heating coil at its centre, and its photospheric layers by s', a thin coat of asbestos, paint, or other substance Varying the substance of s' represents varying the photospheric conditions of a star, we want to find how interior conditions depend on s' Milne solves the problem wrongly, as I think, and concludes that the sphere coated with asbestos will be " much hotter inside " than one wholly of copper, " for it is jacketed by a bad conductor " As every plumber knows, this is not so, only a thick layer of asbestos will make things much hotter inside It is, I think, the same with the stars Whatever the photospheric conditions, the photospheric layers are not thick enough to make any real difference

Thus Milne's involved procedure of integrating inwards, getting infinite or zero density, and then letting masses of unsupported gas crash to finite densities seems to me all unnecessary, he could have assumed a finite central density to begin with and integrated outwards, and as this is the exact procedure followed in my theory I cannot see how our final results can be different—unless one of us makes a mistake in analysis or arithmetic

It is, of course, also the procedure followed by Eddington in his classic papers Where I differ from Eddington is not on general questions of procedure, it is that he thinks a star's centre must be gaseous, whereas I do not Also, we differ as to whether his very restricted model with $\kappa\eta$ constant is a very good or a very bad model Milne appears to have followed Eddington so far in tying himself down to this particular restriction Unless I am greatly mistaken, all that is essentially novel in his theory (as shown in Figs 1 and 2 in his NATURE article) will vanish to nothing as soon as he frees himself from this impossible and misleading restriction

Aurora Display and Magnetic Disturbance

ON Saturday evening, Dec 20, at about 18 h 35 m, I noticed that the sky was strongly illuminated along the northern horizon, the light extending about 40° in azimuth, with its centre, as near as could be estimated from the position of the pole star, true north, and a maximum altitude of about 15° It was at once suspected as an auroral arch, but as the magnetic curves which had come off that morning showed the magnetic conditions to be exceptionally quiet, some doubt was felt as to the auroral character of the light A suspicion was entertained that it might be due to the illumination of a sheet of very high cloud, though the sun was far below the horizon This, however, appeared unlikely, both from the length of time after sunset and from the fact that there was no illumination over the western or north western horizon

The light was kept under observation, and was very steady, with no indications of streamers, though once or twice there was a suspicion of a flicker higher up in the sky At about 18 h 50 m the light began to fade out, commencing at the eastern end of the display, and at 18 h 55 m the last traces at the western end had disappeared

That this phenomenon was an auroral display is confirmed by the magnetic curves which came off on the morning of Dec 22, which show that a quite notable magnetic disturbance was in progress at the time

The magnets began to be slightly disturbed at about 16 h, a 'bay' forming in the declination trace, centred at about 17 h 10 m and the horizontal force falling to a minimum at 17 h The most notable feature of the disturbance was the fall in value of the declination from a maximum at 18 h 2 m, to a minimum at 18 h 53 m through a range of 39′ The major

portion of this fall occurred at a practically uniform rate between 18 h 28 m and 18 h. 53 m, during which interval the range was 31′, followed by a sharp rise of 18′

The chief feature of interest in this observation is that the auroral light persisted whilst the declination value was falling rapidly, and ceased at practically the same moment as that fall ceased There is some doubt as to the exact moment when the auroral light ceased to be visible It was certainly not later than 18 h 55 m, but it may have been from one to two minutes earlier

Now if the aurora and magnetic disturbance be attributed to a stream of ionised particles emanating from the sun and reaching the earth's upper atmosphere, consideration of the above conditions enables us to assign the nature of the charge carried by the particles For such a stream would, in the northern hemisphere, be proceeding from lower to higher latitudes, and descending earthwards in the vicinity of the pole, and considering such a stream as equivalent to an electric current, the application of Clerk Maxwell's 'corkscrew' rule shows that to produce a diminution of the westerly component of the earth's magnetic field (a decrease of westerly declination), the charge carried by the particles must be negative

When the stream ceased, it would be expected that both the ionisation of the upper atmosphere, causing the auroral light, and the magnetic deflecting force would cease at about the same time That the light should have first faded out at the eastern edge, and persisted longest at the western, remains unexplained

It is worth noting that this magnetic disturbance, though not very large, is one of an unbroken sequence at approximately 27 days' interval, persisting since December 1929 The eruption on the sun observed with the spectrohelioscope at Greenwich on Nov 25, as noted in NATURE of Dec 20, occurred about a day after the commencement of the November member of the series

The disturbances of this sequence have commenced throughout with the passage of solar longitudes 120° to 150° over the central meridian of the visible disc, and have lasted for 8 to 10 days, coming to an end with the meridian passage of solar longitude about 30°, thus indicating exceptional activity over the sun's surface between these longitudes throughout the year

The Latent Splitting of Bars undergoing Transverse Vibrations

THE formation of slip bands in bodies subjected to different kinds of stresses has been studied by several observers These have been regarded as dependent on the crystalline nature of the materials More recently A Nadal [1] has given an interesting account of his experiments with marble, paraffin, and several metals, illustrated with numerous photographs

While studying the variation of Young's moduli of materials under low stresses by a method similar to the one described by me,[2] it was noticed that considerable fluctuations occurred in the frequency of a fixed length of a bar when observations were taken over a long period of time These could not be ascribed to any sources of error Further, it was also observed that these distinct frequencies did not vary in any continuous manner, but that certain definite values repeated themselves when a large number of observations was taken For many purposes these fluctuations are usually ignored and a mean value of the frequency determined for a given length of the vibrating bar The observations reported here, however, leave no room for doubt, as others have also pointed out, that a vibrating bar clamped at one end is not a constant source of frequency at all What these fluctuations in reality signify is the purpose of this note to suggest

These fluctuations in frequency can be explained on the assumption that the experimental bar is in reality made up of a number of thinner strips of nearly equal thicknesses coupled together by cohesive forces It has been then found possible to work out a relation between the thicknesses of the component strips of the bar and the distinct frequencies into which the bar as a whole vibrates from time to time—the frequencies generated being the result of the action and reaction of the component parts on each other

If t_1, t_2, t_3, etc, be the thicknesses of the component strips of a bar of total thickness d, so that

$$d = t_1 + t_2 + t_3 + \quad t_N,$$

where N is finite and small, and if n_1, n_2, n_3, etc, be the distinct frequencies of the bar as a whole, it can be shown that

$$\frac{t_1}{t_1 + t_2 + \quad t_N} = \frac{n_1}{n_1 + n_2 + \quad n_N}$$

or $$t_1 = \frac{d\ n_1}{n_1 + n_2 + \ .\quad n_N},$$

and $$t_2 = \frac{d\ n_2}{n_1 + n_2 + \quad n_N},\quad t_3 = \text{etc}$$

Since d, n_1, n_2, etc, are all measured directly, we have here a method of calculating the thickness of the component strips into which the bar, although sound to all appearances, really splits In support of this view of the phenomenon, it is interesting to point out that the actual lines of ruptures, separated by distances exactly predicted from the above theory, have been observed and measured in a large variety of substances under a microscope These rupture lines are very sharp and run parallel to the surface of the bar perpendicular to the plane of its bending The agreement between the calculated and observed values of t's is remarkably good The substances examined so far include, among others, copper, steel, aluminium, marble, slate, and different kinds of wood All these materials show the effect described above very clearly In view of the general nature of the phenomenon common to such different substances as wood and metal, and also in consequence of the fruitfulness of the idea that the experimental bar can be looked upon as made up of a discrete number of thinner bars held cohesively together, it is here suggested that 'latent splitting' is a more appropriate name for the effects observed than formation of 'slip-bands', which seem to refer to crystalline substances in particular

Since the t's and their differences for any material must be an integral number of times the thickness of its ultimate component parts, an interesting application of the theory sketched above leads, with the power of the apparatus used in the present investigations, to a determination in the case of

(*a*) Wood—of the mean diameter of its fibres

(*b*) Metals and stones—of the thicknesses of crystal grains or distances between cleavage planes which are exact multiples of the lattice cell constant as given by X ray analysis Full details of theory and experiments will be published shortly in a paper

in preparation Only a few typical results are given here

Material	t from theory in cm	t from obs in cm	Mean diameter of fibres from theory in cm	Fibre diameter directly measured in cm
Boxwood	0·0746 0 0759 0·053, 0 051	0 075 0 055	6 55 × 10⁻⁴	6 58 × 10⁻⁴
Copper	0 0338 0·0338 0 0449, 0·0665	0 033 0·045, 0 070	The thickness of grain deduced = 906 24 × 10⁻⁸ cm and this is 251 × 3·610 A, where 3 610 A is the value from X ray measurement	
Slate	0·0442, 0 042 0·0381, 0 0370	0 045, 0 040 0 038, 0 037	The thickness of grain deduced = 605 54 × 10⁻⁸ cm and this is 200 × 3 027 A, where 3 02 A is the value from X ray measurement	

The wood fibres were prepared by the Schulze process, and their mean diameters were measured directly under a microscope

Systems of Four Immiscible Liquid Layers

SYSTEMS of three immiscible layers are sufficiently uncommon to be noteworthy, and no system of four layers appears to have been described (excluding systems containing free mercury) Nor is this remarkable when it is recalled, first, that practically all *dry* organic liquids are completely miscible, almost the only exceptions being polyhydric alcohols, secondly, that a system of four liquid phases requires the existence of four substances or solutions, which taken three at a time yield at a fixed temperature four systems each of three liquid phases, the immiscibility of which is in no case destroyed on saturation with the fourth component The majority of the hitherto described systems of three liquid phases (of which the system water–aniline–hexane is typical) owe their existence to the properties of a substance such as aniline or succinic nitrile, which is not completely miscible with water, but itself absorbs sufficient water to destroy its miscibility with another solvent, such as hexane or carbon disulphide, which absorbs only traces of water

A study of systems containing soaps revealed a different type of three-layer system When an electrolyte is added to an aqueous soap solution in equilibrium with an organic solvent not completely miscible with it (or when the soap concentration is increased beyond a certain limit), one of three things may happen

(1) The soap is salted out as solid curd

(2) The soap is transferred completely to the solvent layer

(3) The salted-out soap absorbs water and solvent to form a third layer immiscible with either lye or solvent

The system sodium oleate, sodium chloride, ethyl acetate, water, illustrates all three possibilities the first, for example, at 25°, the second at 55° for high salt concentrations, the third for lower salt concentrations at the same temperature These three layer systems differ from the type previously mentioned in that two of the layers are predominantly aqueous in composition Since such systems can be prepared using either aniline or hexane as the solvent, and since wet aniline, hexane, and water are mutually immiscible, the conditions are fulfilled for a system of four liquid layers, provided the presence of soap in at least three of them does not destroy their immiscibility Suitable proportions do, in fact, yield a four phase system at room temperatures, this is most easily prepared by mixing the organic liquids and oleic acid (which are miscible in the absence of water), and adding sufficient aqueous sodium hydroxide to saponify the fatty acid and salt out the soap The following proportions yield approximately equal volumes of the four layers

Hexane (or light petroleum)	12 c c
Aniline	7 c c
Oleic Acid	0 5 c c
Alcohol	1 5 c c
Aqueous Sodium Hydroxide – 0 8N	10 c c

The alcohol is not essential to the system, but reduces the time required for separation of the layers from hours to minutes An increase of temperature or of electrolyte concentration renders miscible the hexane and aniline layers (first and third from the top), which then form the top layer

This four-phase system contains five components (excluding the alcohol), which is one more than the minimum required by the phase rule Although both aniline and hexane could probably be replaced by other liquids, there seems to be no possibility of producing a four phase system of this type with only four components

It need scarcely be added that the addition of mercury gives a five layer system—a unique scientific curiosity

The Longitudinal Distribution of Photoelectrons

FORMULÆ of the type

$$P(\theta)d\theta \propto (A + B\cos\theta)\sin^3\theta d\theta \qquad (1)$$

as a first approximation to more complex forms have been proposed as illustrating the existence of longitudinal asymmetry in the spatial distribution of photoelectrons [1] Here $P(\theta)d\theta$ is the probability of photoelectric emission between angles θ and $(\theta + d\theta)$ to the ray, A is usually unity and B some function of the frequency of the incident radiation and of the atomic number of the atoms upon which the radiation falls The angle of bipartition θ_b is then obtained from the relation

$$\int_0^{\theta_b}(A + B\cos\theta)\sin^3\theta d\theta = \int_{\theta_b}^{\pi}(A + B\cos\theta)\sin^3\theta d\theta \qquad (2)$$

and the average forward momentum

$$\overline{mv\cos\theta} = mv\int_0^{\pi}(A + B\cos\theta)\sin^3\theta\cos\theta d\theta \Big/ \int_0^{\pi}(A + B\cos\theta)\sin^3\theta d\theta \qquad (3)$$

I should like to point out that from another point of view the distribution formula (1) does not give the information concerning θ_b and $\overline{mv\cos\theta}$ that is ascribed to it A similar expression can be built up from quite simple principles, which, however, preclude us from performing any integration outside the limits 0 to $\pi/2$

Assuming the wave mechanical principle of interference $P(\theta) \propto \sin^2\theta$ and that independent groups of photoelectrons originate from a small plane circular area of radius b normal to the ray and a small spherical volume of radius a respectively, situated at the origin, we could write down at once the whole probability

$$P(\theta)d\theta \propto (A'\pi a^2 + B'\pi b^2\cos\theta)\sin^3\theta d\theta \qquad (4)$$

where A' and B' are factors independent of θ

From the way in which the problem is stated and because of the inclusion of the cosine term involving

negative probabilities, expression (4) must be regarded as unilateral and integrable only between the limits 0 to $\pi/2$ If the other half of the spherical aperture surrounding the origin is to be considered, the ray must be reversed Everything would then be symmetrical about the plane $\theta=\pi/2$, there would be no justification in drawing any other conclusions with regard to θ_s or to the average forward momentum Of course, if equation (4) is integrated as in (2) and (3) it will yield results which are obviously fictitious

That longitudinal asymmetry exists has been abundantly shown by experiment It is introduced in the Compton effect, and it is apparent that the probability of the interaction between a photon and an electron must depend on some mutual directional relationship existing between the two during the period of interaction LEWIS SIMONS

Part-Absorption Phenomena of X-Rays

IN connexion with the partly absorbed lines observed by Ray (NATURE, May 17, p 746, June 7, p 856, Sept 13, 1930, p 399), I have observed the following lines, using similar arrangements

Incident Radiation	Absorbing Substance	Modified Lines	Origin
Fe$K\alpha_{1,2}$ (471 0)	C	2022 X U (450 6)	Fe$K\alpha_{1,2}$ – C$K\alpha$ (20 4)
,,	N	2053 X U (443 8)	Fe$K\alpha_{1,2}$ – N$K\alpha$ (27 2)
,,	Al	1975 X U (461 4)	Fe$K\alpha_{1,2}$ – AlL_1 (9 6)
Fe$K\beta_1$ (519 9)	,,	1784 X U (510 8)	Fe$K\beta_1$ – AlL_1 (9 1)
Ni$K\alpha_{1,2}$ (550 0)	,,	1688 X U (540 0)	Ni$K\alpha_{1,2}$ – AlL_1 (10 0)

The figures in the bracket indicate the values of ν/R

A current of 7 ma was passed through the X ray tube at a peak voltage of 24 kv The transmitted beam was analysed by a calcite crystal

The appearance of the lines with aluminium as the absorbing substance is rather interesting Though the actual value of AlL_1 is not known, the theoretical value obtained by Mukherjee and Ray (*Zeit f Phys*, vol 57) is 9 2 (ν/R) As yet I have not observed any line having $K\alpha_{1,2}$ – AlL_2 as origin This seems to be in accordance with the observations of Robinson, who found that if the energy of the incident quanta is large when compared with those of L levels, the L_1 absorption edge has a much greater intensity than that of L_2

The partly absorbed lines are diffuse and have a definite breadth, and as such they can be selected from known faint lines The breadth of the lines, when measured in volts, approximates to the ionisation potential of the atom in question, and thus points to the fact that the electron, which is lifted from the original level to the periphery or to any other optical level by the part absorption of the radiation, is not removed from the atom completely

In this connexion it may be pointed out that as the partly absorbed lines are very weak and diffuse, great precautions were taken to reduce the blackening of the plate from the general radiations, especially from higher orders, as much as possible, by decreasing the voltage and increasing the current through the X-ray tube Further, by varying the thickness of the absorbing layer and the time of exposure, a condition was found where the best photographs were obtained in about 8 hours Agfa Röntgen films are more suitable for this type of work than ordinary plates R C MAJUMDAR,

The Equivalence of the Valencies of Carbon

I POINTED out some time ago,[1] that despite Pasteur's original statement, or at all events, the text book version of it, optical enantiomers were possibly not completely identical I followed this up with an investigation of the rotatory powers of the mandelic acids,[2] in which at least preliminary evidence of non identity was obtained I am about to publish an account of a lengthy investigation of the camphoric acids, in which differences of the same kind have been observed

In the paper to the Faraday Society (loc cit) I pointed out that a probable consequence of the non identity of enantiomers would be that, in the language of the tetrahedral conception, the carbon valencies were not symmetrically distributed in space, and that, therefore, numerous unsuspected isomers, differing only slightly in physical properties, should exist It therefore behoved us to investigate anew the properties of such bodies as methylene chloride, bromide, and iodide, the supposed non-existence of isomers of which was formerly adduced as evidence in favour of the tetrahedral, as opposed to the plane, distribution of the carbon valencies I am, of course, not contending for a plane distribution of valencies It is of interest that my suggestion of alternative orbits for an electron in the same atom has been brought forward independently as an explanation of the existence of 'electro-isomers'

As a preliminary to commencing work upon the methylene halides, I read through the literature on the subject, or at least such of it as is accessible to me here, and I was surprised to find that two crystalline modifications of methylene iodide are already known to exist [3] Polymorphism is not considered as evidence of chemical difference, but merely of difference in crystal lattice, but one may be permitted to ask, why should alternative lattices be possible, if the molecules themselves are identical in size, configuration, and fields of force? The obvious method of attack here is to investigate the melts obtained from each form, after the manner in which the keto enol transformation has been investigated, and this I shall proceed to do In my opinion, two modifications of methylene bromide and of methylene chloride would also have been observed, had not these bodies been liquid at and below room temperature

Relation of the Liquid to the Crystalline State

IN a recent note E Gross has found that the Debye elastic heat waves also give rise to modified scattering in liquids [1] The fact that electromagnetic waves are modified by the elastic heat waves shows that the origin of the latter in liquids is also electrical and akin to lattice oscillations in crystals In order to explain facts connected with X ray diffraction in liquids, it

was found that a liquid has to be regarded as a broken up crystal in which there is thermodynamic equilibrium between heat motion and forces of crystal formation.[2] It was seen both theoretically and from observations on X-ray diffraction that there is a maximum in the molecular arrangements in liquids corresponding to the structure of the substance in the crystal state. It is evident that this partial crystallinity of liquids is responsible for the modified scattering found by Gross. It is, therefore, expected that those liquids which produce sharp diffraction effects should also produce sharp modified lines, and it will be interesting to see whether that comes out true.

In the same paper Gross suggests an instructive explanation of the broadening of Raman lines that each Raman line consists of a number of unresolved lines modified further by the elastic heat waves; he supports this view also in his later paper.[3] This does not appear to me sufficient to explain the fact that in some cases where he observed modified scattering due to elastic waves there is no broadening of the Raman lines. The following explanation appears probable to me. In a crystal the natural frequencies of a molecule that are responsible for the Raman effect are modified, due to the surrounding molecules; but on account of the regular arrangement all the molecules are affected in the same manner, and hence Raman lines are sharp. But in a liquid the regularity of arrangement is broken, and hence the broadening out of the natural frequencies of the molecules. We may, therefore, say generally that the more diffuse the X-ray diffraction of a liquid the broader are its Raman lines, provided the natural frequencies of molecules are sufficiently influenced by the surrounding molecules.

The Photo-Reaction of Hydrogen and Iodine Monochloride

WE are unable to accept the conclusions of Rollefson and Lindquist[1] that hydrogen and iodine monochloride do not react at ordinary temperatures under the influence of light. These authors maintain that the reaction $H_2 + Cl = HCl + H$ does not readily take place because the Cl atoms resulting from the photo-dissociation of ICl are mostly in the unexcited state. They consider that the accompanying reaction $ICl + Cl = I + Cl_2$ is more probable. We had already concluded certain experiments with H_2 and ICl before the above paper appeared, and had found, as we now find on repeating the work, that H_2 and ICl reacted rapidly in strong light if the hydrogen pressure were large compared with the pressure of ICl. This must mean that conditions favour the greater probability of the reaction $H_2 + Cl = HCl + H$, and that excited Cl atoms may not be necessary for it to take place. The idea, however, that ICl dissociates into normal atoms is not accepted now by the original investigators.[2]

In some of our preliminary experiments we passed carefully purified hydrogen at atmospheric pressure and ICl at a pressure of about 20 mm. into thin glass bulbs, which were then sealed off. The reaction was very slow in artificial light (electric globe), more rapid in diffuse daylight, and very rapid in direct sunlight, I_2 and HCl being the main products. We have also used hydrogen filtered through palladium and dried over phosphoric oxide, and Kahlbaum's purest, crystalline ICl. No special precautions were taken to eliminate possible inhibitors except oxygen. It is easy to understand why the reaction proceeds very slowly compared with the hydrogen chlorine reaction, as the chain will terminate with the formation of iodine atoms.

We hope to publish some quantitative results very shortly.

Crystal Structure of Molybdenum Trioxide

CRYSTALS of molybdenum trioxide, prepared by subliming MoO_3 powder, obtained from the pure ammonium compound, have been examined with X-rays. The crystals were small, thin, lustrous plates, parallel to b (010).

Laue photographs showed orthorhombic symmetry. Oscillation photographs about the three principal axes gave the cell size as

$$a = 3.93 \pm 0.02 \text{ A}$$
$$b = 13.91 \pm 0.05 \text{ A}$$
$$c = 3.57 \pm 0.02 \text{ A}$$

These seem to bear no relation to the crystallographic axial ratio given by Nordenskiold,

$$a : b : c = 0.3874 : 1 : 0.4747.$$

There are four molecules of MoO_3 per cell. The space group is Q_h^{16}, (bnm), since $(h0l)$ is halved if $h + l$ is odd, and $(0kl)$ is halved if k is odd. The co-ordinates of the molybdenum atoms are as follows, the centre of symmetry being taken as origin:

$$uv\tfrac{1}{4};\ \bar{u}+\tfrac{1}{2},\ v+\tfrac{1}{2},\ \tfrac{1}{4};\ u+\tfrac{1}{2},\ \bar{v}+\tfrac{1}{2},\ \tfrac{3}{4};\ \bar{u}\bar{v}\tfrac{3}{4}.$$

$u = 36°$, $v = 30°$ approximately.

Intensity measurements are being made on an ionisation spectrometer to fix the oxygen positions.

A full account of the structure will appear later in the *Zeitschrift für Kristallographie*.

The Emission Bands of Sulphur

H. H. VAN IDDEKINGE[1] has made the interesting observation that in the emission spectrum of sulphur produced by him such of the bands as were found by Rosen[2] and Henri and Teves[3] to be diffuse in the absorption spectrum, are entirely absent. This gives strong evidence in favour of the view of 'pre-dissociation' in the molecule.

A few months ago, when I was working at King's College, London, I obtained spectrograms of the emission bands of sulphur by exciting them in a discharge tube containing sulphur vapour in the presence of high pressure argon. Analysis of the bands is in progress, but I find on my plates all the bands recorded in absorption by previous workers and many more towards the red end, and the bands are all sharp. This indicates that argon helps in some way to arrest the pre-dissociation of the sulphur molecule. Analogous influences of rare gases are known, for example, in the production of the Cameron bands, the Baldet-Johnson bands, etc.

In addition to the already known bands attributed to sulphur in the visible and the ultra-violet, a few new bands degraded towards the shorter wave-length side have been also photographed in the extreme ultra-violet beginning from about $\lambda 2100$,

This system apparently extends into the region of the vacuum spectrograph, but until now I have not been able to make any attempt to photograph them there

An Unusual Sex-Ratio in Red Deer

IT is the practice among stalkers in the deer forests of Scotland to shoot a certain proportion of the hinds each year after the stag shooting season has finished So far as possible the hinds chosen are those called 'yeld' or dry hinds A 'yeld' or dry hind is one which did not have a calf during the preceding season It may either never have had a calf or may have missed a season Consequently the 'yeld' hinds have no calf following them They are almost always pregnant at the time they are shot

In September 1927, whilst staying at Langwell, Caithness, I was informed by H G the Duke of Portland, K G, of a very wide-held belief amongst deer stalkers that these 'yeld' hinds always had a male embryo in the uterus and never a female The Duke, being interested in this matter, sent me six pregnant uteri from 'yeld' hinds shot at the end of 1927 On opening them it was found that five of the embryos were male and one female * In 1928 I received 17 uteri Apparently the hinds had been shot much earlier in the season, for in none of these cases was it possible to determine the sex by ordinary visual examination The genital glands from the base of the kidney were accordingly sectioned, and it was taken that the presence of testicular tissue was positive evidence that the embryo was a male Of the 17 uteri, *one* proved not to contain an embryo at all, and in 3 other cases identification was impossible The remaining 13 embryos were all male

It will be seen that of the cases examined, in which it was possible to sex the embryos, 18 were males and only one female

I feel bound to mention that on arrival at Langwell in 1928 I was informed by the stalkers that one of the 1927 uteri had been sent by mistake, and that it was in all probability not taken from a 'yeld' hind, but even without relating this to the single female in the 1927 cases, the figures appear sufficiently striking

I am deeply grateful to the Duke of Portland, not only for his original suggestion, and for sending the specimens, but also for the kindly interest he has taken throughout

I am also greatly indebted to Dr H S Davidson and Dr J S Sturrock, of the Obstetrical Department of the University of Edinburgh, who prepared the sections of the sex glands, and to Prof Arthur Robinson, of the Anatomy Department of the University of Edinburgh, who finally identified the preparations

* The Duke incorporated these results in a letter on this subject published in the *Field*

Behaviour of a New Species, *Digitalis mertonensis*

HYBRIDS have often been obtained between *Digitalis purpurea* and *D ambigua*, but it was not until 1926 that a few F_2 seedlings were raised by crossing such hybrids *inter se* [1]

These seedlings were giant, highly fertile, and showed no segregation of the parental characters They had 112 chromosomes and arose by a suppression of the reduction division in their parents, each of which had 56 chromosomes. The inference was drawn that, as in other cases, it was the doubling of the chromosome number that *determined* the regular pairing of identical chromosomes, the formation of uniform germ cells, and consequently fertility

The new form has been carried on for five generations and remains giant and tetraploid The linear measurements of the flowers are $\sqrt[4]{2}$ times those of the diploid hybrid It throws about a quarter of less fertile forms at each generation These are presumed to arise through the occasional pairing and segregation of the homologous chromosomes derived from the opposite parents, as in *Primula kewensis* [2]

It crosses with the parental species, readily with *D purpurea*, less readily with *D ambigua*, but yields offspring which, being triploid, are highly sterile There is no difficulty, therefore, in preserving the new form effectively uncontaminated by crossing, and we consider that it can conveniently be regarded as a new species *Digitalis mertonensis*

Amongst the rare seedlings of *D mertonensis* × *D ambigua* was one small sterile plant showing all the characteristics of the F_1 hybrid and none of the characteristics of the back-cross This plant proved to be diploid At meiosis its chromosomes failed to pair, as in the original hybrid It can only have arisen from an unfertilised germ-cell of its female parent, that is, by parthenogenesis Thus the halving of the chromosome number is associated with the removal of all the conditions associated with the doubling

Since we see that (1) the halving of the chromosome number is directly determined by omission of fertilisation (an intercellular phenomenon), while the doubling of the chromosome number is directly determined by the omission of reduction (an unrelated, intracellular phenomenon), and (2) in both cases the difference between high and low chromosome number is associated with the difference between fertility and sterility, it follows that the change of chromosome number is the cause of the change of fertility rather than a parallel effect of a common cause

The Designation of Women Biologists

I WAS very glad to see from Prof Cockerell's letter in NATURE of Dec 20, that scientific men now realise the importance of continuity in a woman's name When I first married in 1911 and kept my own name I had to overcome the opposition of a number of the leading scientific people of that day, who bitterly objected to my utilising the laws of our country, which permit a woman *not only to use* her maiden name throughout her married life, but also retain it *as her only legal name* The Royal Society even refused to continue a grant which I had from it unless I adopted my husband's name! So may I, as one who persistently kept her own name for scientific work (and has borne the brunt of the difficulty of doing so against an unreasoning antagonism), welcome and support Prof Cockerell's suggestion that all women should do so?

Vitamin B

Assay and Vitamin B_1

THE separation of vitamin B into two factors, antineuritic and antipellagrous, a few years ago, led to considerable attention being devoted to the properties of this vitamin, with the result that it is now possible to distinguish at least four B factors, quite apart from any grouped under the name 'Bios', which may be necessary for the growth of lower organisms The factors are distinguished by differences in their chemical properties and physiological effects their differentiation has necessitated a revision of the methods of assay, since it is possible that a failure to respond to an addition to the diet is an indication of the absence of a factor other than that for which the test was designed In this type of research a preventive test is less delicate than a curative, whilst the growth test may be considered still cruder a single factor should cure the specific symptoms due to its absence, preventive tests may test for more than one, whilst it is clear that a positive growth response can only be obtained when every factor is adequately supplied, and our knowledge of all the factors required for growth is still incomplete, as the recent work on vitamin B has shown

H W Kinnersley, R A Peters, and V Reader (*Biochem Jour*, vol 22, p 276, 1928) have analysed the pigeon curative test for vitamin B_1, or the antineuritic factor By adherence to certain principles, the test can be made reasonably accurate and has been successfully used in following the vitamin in its concentration from a yeast extract The birds should be in the laboratory for a month on a mixed grain diet before being placed on the diet of polished rice, and only those developing symptoms within 30 days should be used As soon as signs of head retraction appear, the bird should be transferred to a warm room for 2 hours and given 50 mgm glucose in water by stomach tube this procedure eliminates birds showing false cures The dose of extract must be given within 6-12 hours of the onset of symptoms and, provided the cure lasts more than 1 and less than 10 days, the amount of active principle present can be considered as directly proportional to the length of the cure After the test is over, the bird is given marmite and kept warm for a few days It is then placed on the stock diet again for about a month, when it is ready for another period of polished rice feeding Individual birds show a remarkable constancy in the time symptoms appear after commencement of the experimental diet, but there is no correlation between this interval and the duration of the subsequent cure, or between it and the colour or weight of the bird

H Chick and M H Roscoe (*ibid*, vol 23, p 498, 1929) have used the growth of young rats as a criterion for the presence of vitamin B_1 It is difficult to carry out a curative test with this animal, since there is only a very short interval between the onset of acute symptoms and death Reader has, however, been successful and has found that the adult rat requires about one pigeon day dose each day (quoted by Peters, the Harben Lectures, 1929) Chick and Roscoe used synthetic diets free from vitamin B_1 vitamin B_2 was supplied as autoclaved yeast or as fresh egg-white After 2 3 weeks the animals began to lose weight growth was resumed if Peters' antineuritic concentrate was then administered The egg-white diet, however, did not maintain growth to maturity B C Guha and J C Drummond (*ibid*, vol 23, p 880, 1929) have used both the pigeon curative and the rat growth tests in the latter, vitamin B_2 was supplied as marmite autoclaved at an alkaline reaction

Chick and Roscoe (*ibid*, vol 22, p 790, 1928) have used a similar method for the assay of vitamin B_2, young rats being placed on a diet complete except for this vitamin, and the B_1 factor being supplied as Peters' concentrate It was found that the caseinogen used contained traces of vitamin B_2 unless it was reprecipitated with acetic acid and thoroughly extracted with alcohol before being heated at 120° Animals on this diet fail to grow but respond to a supplement containing vitamin B_2 If the supplement is not given, after about six weeks a generalised dermatitis appears, which can be cured by administration of the vitamin

B C P Jansen and W F Donath (*Mededeelingen van den Dienst der Volksgezondheid in Ned Indië*, Anno 1927, Part 1) obtained highly active preparations of vitamin B_1 from rice polishings by a process involving extraction with acid water, adsorption on fuller's earth, elution with baryta, and fractionation of the extract with silver sulphate and baryta The activity was precipitated with phosphotungstic acid, the precipitate decomposed with baryta, and after removal of barium the concentrated solution was treated with platinic chloride, which precipitated the vitamin Further purification was effected by acetone precipitation from alcoholic solution and by treatment with picrolonic acid or gold chloride 0·012 mgm of the final fraction a day was sufficient to maintain pigeons in health over six weeks C Eykman (*Kon Akad van Wetensch Amsterdam*, vol 30, p 376, 1927) confirmed the activity with both pigeons and cocks The final product was obtained in crystalline form, as a hydrochloride, a picrolonate, or a double salt with gold chloride

Kinnersley and Peters (*Biochem Jour*, vol 22, p 419, 1928) have continued their work on antineuritic yeast concentrates (see NATURE, vol 121, p 516, 1928) It is not yet certain whether the curative substance is the same as that obtained from rice polishings by Jansen and Donath the activity of the final product does not appear to be quite so great and its properties are not quite the same In all work on the concentration of vitamin B_1, it has been found that the properties of the active fractions vary according to the nature of the accompanying impurities, so that methods developed for use with an extract of rice polishings may not be applicable without modification to an extract of yeast The extract from the charcoal adsorption, after removal of metals, can be fractionated by successive additions of alcohol, the

vitamin passing into the portion soluble in 99 per cent ethyl alcohol The authors failed to get consistently successful results with a silver fractionation, but were more successful with the use of phosphotungstic acid and platinic chloride The most active preparations contained a day dose in 0 027 mgm , but more lately some have been obtained with a curative activity of 0 01 mgm a day dose

Guha and Drummond (*loc cit*) prepared active concentrates from wheat embryo After extraction by means of acid alcohol, two different methods of concentration were employed in the first, impurities were precipitated by lead acetate, and the activity adsorbed on norite charcoal at pH 4 5 and eleuted with acid alcohol it was then precipitated by phosphotungstic acid, adsorbed on silver oxide, and the product fractionated with alcohol Picrolonic acid then precipitated impurities from the material, which was soluble in alcohol The first product had a pigeon day dose of 0 043 mgm In the second method, Jansen and Donath's process was followed, namely, adsorption on fuller's earth at pH 4 5 and eleution with baryta, and fractionation with silver nitrate and baryta followed by precipitation with phosphotungstic acid The product was then submitted to precipitation with platinic chloride, followed by gold chloride, at the last stage most of the activity passed into the precipitate, but it was observed that smaller doses of both precipitate and filtrate together restored growth in the rat or cured the pigeon than of either when given separately, suggesting that vitamin B_1 may itself be composed of more than one factor The smallest pigeon day dose was 0 0025 mgm , and 0 015 mgm promoted good growth in rats These figures indicate that the preparations were more active than the crystals obtained by Jansen and Donath

Although formulæ have been assigned to vitamin B_1 preparations, it does not appear that a pure substance has yet been isolated A certain amount is, however, known about its properties It appears to be a tertiary base it is soluble in water and alcohol, but is unstable in the latter solvent when highly purified it is insoluble in the other common organic solvents It is destroyed by alkali, but is stable to oxidising and reducing reagents and to nitrous acid Cruder preparations give a definite Pauly reaction, but as purification proceeds the reaction becomes very weak Sulphur is absent and the purer preparations do not give the xanthoproteic, purine, or Millon's reactions In extracts from rice polishings, after treatment with lead acetate and concentration of the filtrate, vitamin B_1 is destroyed by fermentation and by heating to 95°, and is removed by filtration through a Berkefeld filter (J L Rosedale and C J Oliveiro, *Biochem Jour* vol 22, p 1362 , 1928), although it will dialyse through cellophane

The isolation from contentrates of supposedly pure substances and the fact that false positives may be given by the pigeon test have led to claims that different pure compounds are the vitamin J M Gulland and Peters (*ibid* , vol 23, p 1122 , 1929) have examined the claims that certain quinoline and glyoxaline derivatives have curative properties Without exception all those examined, including 4 (or 5) glyoxaline methylethyl carbinol hydrochloride and 2 6-dihydroxyquinoline, were quite inactive when tested on pigeons by Peters' technique

The Adler Planetarium of Chicago

THE Adler Planetarium is a new and striking feature on the shore between a small lagoon and Lake Michigan In plan it is dodecagonal the walls are faced with large slabs of red granite and it is surmounted by a dome The principal object of this new institution is explained on the dedication plaque that confronts the visitor when he crosses the threshold of the entrance lobby Eight sculptured figures by Vannelli, symbolising the eight principal planets, are disposed around a circular disc representing the sun, upon which is set the inscription "*The Astronomical Museum and Planetarium of Chicago—Gift of Max Adler—To further the Progress of Science—To guide to an Understanding of the Majesty of the Heavens—To emphasise that under the Great Celestial Firmament there is Order, Interdependence and Unity—1930* "

For this purpose the principal instrument is a large projection apparatus built by the firm of Zeiss on lines similar to those of the one described in NATURE for Dec 27, 1924, p 937, and by which large audiences can watch the movements of the starry firmament as projected upon the inside of the great dome of 68 feet in diameter On the north and south sides of the dome are two spacious exhibition halls, while to the east of it are library, lecture- and work rooms, and also the office of the director, Dr Philip Fox

The Adler Planetarium is, however, designed on broader lines than those of a public hall for planetary demonstrations It includes a collection of important historical instruments used by astronomers in past centuries Among the more modern instruments are one of Sir William Herschel's reflecting telescopes, given by Sir Frank Dyson with the authorisation of the British Admiralty , Burnham's 6 inch telescope, loaned by the University of Wisconsin, with various mementoes of him , Nichol's star heat radiometer from the Yerkes Observatory , refractors loaned by Carl Zeiss and by Richard E Schmidt , a large model of an observatory with movable dome, telescope, and floor, based on the U S Naval Observatory An appropriate exhibit is an orrery by Isenbroeck, of 1737 , while in wall-cases are displayed that important series of instruments of earlier date, known as the Mensing Collection, which was purchased *en bloc* in January last by Mr Adler from the firm of Messrs Frederik Muller and Co , of Amsterdam

While keenly regretting the loss to Europe of so many astrolabes, armillary spheres, sundials

early telescopes, sextants, and surveying instruments—all most interesting relics of the past—it is well that the great country of America, where science is relatively so new, should have some material record of the tools by which astronomical knowledge has been painfully won, and taught, in the Old World. Thanks to the generosity of yet another recruit to the ranks of noble benefactors who have given the United States its greatest institutions, Chicago now takes the lead among American cities equipped for the study of the instruments of ancient astronomers. Thanks to Dr. Adler, within a few months the city has acquired historical riches surpassed only by the famous collections of European cities, such as Munich, Dresden, Paris, London, and the Lewis Evans Collection at Oxford. The selection has been ably made and arranged by Mr. Adler's lieutenant, Dr. Fox, and the instruments will be on view at the Chicago Centenary Exhibition this year, with the planetarium as the most considerable side show. We require benefactors like Mr. Adler in Great Britain.

Obituary

SIR OTTO BEIT, K.C.M.G., F.R.S.

DURING the last fifty years, and more especially in the last twenty-five, much has been done in Great Britain to promote the advancement of the science of medicine, by providing facilities for the furtherance of research, both by the development of laboratories of high efficiency and also by the foundation of research fellowships to enable investigators of promise to pursue their work. Many generous benefactors have taken a part in this work; some have built institutions or laboratories, others have endowed professorships, and others have founded research fellowships.

Amongst those who have devoted their benefactions to the foundation of fellowships, the name of Sir Otto Beit will always be honoured, not merely, or even mainly, for the magnitude of his foundation, which amounted to nearly a quarter of a million sterling, but rather for the breadth of view that determined the scope of the scheme that was founded as a memorial by him to his brother, the late Mr. Alfred Beit. Mr. Alfred Beit had taken a considerable interest in certain proposals that had been made in the early years of the present century for improving the teaching of the earlier subjects of the medical curriculum of the University of London, and had made a gift of £25,000 towards this object and bequeathed a further like sum for the same purpose. The scheme failed to secure the necessary support of those concerned, and, consequently, the gift and the legacy ultimately lapsed, and reverted to the residuary legatee, Sir Otto Beit. He decided to use the money to establish a memorial to his brother, to whom he was devotedly attached; and after consultation with, and advice from, Sir James Kingston Fowler, the late Prof. Starling, and others, the scheme was promulgated in December 1909 as a "Memorial to his brother, Mr. Alfred Beit, to promote the advancement by research of Medicine, and the Allied Sciences in their relation to Medicine."

Although the scheme was originally drafted on the basis of the provision of a capital sum of £25,000 and the foundation of three fellowships, it transpired that Sir Otto had increased the benefaction tenfold, and one, at any rate, of his advisers only learnt this by telephone from him, twenty-four hours before the announcement was made publicly. This act exemplifies not only the great generosity of the donor, but also the decision with which he acted when he considered the proposals put before him were such as to deserve support.

Although the Foundation is justly remarkable for its magnitude, it is more especially to be commended for its scope. Many benefactors would have desired to impose limitations; some would have failed to realise that medicine can be furthered in any other way than by research directed to some immediate so-called practical object, for example, the eradication of some individual disease. Not so in the case of Sir Otto Beit; and hence the inclusion in the scheme of the "Allied Sciences in their relation to Medicine." He was well aware of the close and intimate connexion of many sciences, not only with the science of medicine, but also with the practice of the art of medicine.

The actual scheme of administration of the Foundation was modelled on that adopted by one of the City companies, namely, the Worshipful Company of Grocers, in its scheme for the award of the well-known Grocer Research Scholarships in Sanitary Science. This City company in the early 'eighties established three scholarships for the promotion of research into the nature and prevention of disease, and always allowed its scientific advisory committee a wide discretion in interpreting the relation of the proposed research to the actual practice of medicine; and many Grocer scholars have made notable additions to knowledge in physiology and in pathology as well as in pure medicine, and thus medicine has been assisted both directly and indirectly. This same policy has characterised the awards of the Beit Fellowships; and the record of the discoveries of the Beit fellows in the course of the last thirty years is one of which any Foundation might be justly proud. Sir Otto Beit, as chairman of the Beit Trustees, took a personal and active interest in the work of the fellows, and was remarkably conversant with their work, as throughout his life he took a lively interest in the progress of medical knowledge.

In November 1928 he made another very notable benefaction to medical science, by giving King Edward's Hospital Fund £50,000 for the purchase of radium for the benefit of London hospitals; and shortly before his death he gave a further £8000, required by King Edward's Hospital Fund to complete the purchase of a further quantity of radium. Here again the value of the gift was greatly increased by the wise foresight of the donor. Many donors would have been satisfied by merely providing radium for the relief of suffering, but Sir Otto Beit went much further by saying that he "should

like the Committee to endeavour to secure that the hospitals thus to be provided on loan with radium, should be preferably those in which the cure of disease, or the alleviation of suffering, is associated with a keen interest in the furtherance of knowledge 'for the relief of man's estate'"

This shows very clearly the wide view and the profound interest he took in the advance of knowledge, and his great faith in the paramount necessity of research Few laymen had such an intelligent appreciation of the problems of medical research, and of the need of much patient work before the realisation of success, and he was not one who was always expecting immediate and striking results to follow on a programme of work

Sir Otto Beit was elected a fellow of the Royal Society in 1924, and certainly it may be said of him, in the words of the statutes of the Society, that he had "rendered conspicuous service to the cause of science" JOHN ROSE BRADFORD

ON the death of Sir Julius Wernher in 1912, Sir Otto Beit took his place as a representative of the Crown on the Governing Body of the Imperial College of Science and Technology, thus preserving unbroken the close connexion of the College with the famous firm of Wernher, Beit and Co Sir Julius Wernher himself was an original member of the Governing Body, and took an influential part in the negotiations which led to the foundation of the College in 1907 Practically the whole of the endowment of the College since its incorporation has been provided by Sir Julius Wernher, Mr Alfred Beit, and Sir Otto Beit

Sir Otto Beit was an active and inspiring member of the Governing Body A firm believer in the intellectual and practical value of the highest scientific education, he did everything in his power to promote it In 1913 he created a Trust Fund, which he increased later to £26,500, to provide for Research Fellowships tenable at the College and open to men and women of European descent by both parents, but otherwise of any nationality, being graduates of universities within the British Empire From time to time he gave sums of money, amounting to £32,500 in all, towards the cost of the Imperial College students' hostel and of the extension to the hostel and the students' union which forms part of a new building now nearing completion His other gifts, which were many in number, included a sum of £10,000 towards the general development of the College in a time of financial stringency

These benefactions are illustrative not only of Sir Otto Beit's generosity, but also of his good judgment He never gave money away indiscriminately, he had a clear insight as to the right thing to do at the right moment He was always ready to be guided, but never allowed himself to be swamped by the enthusiasm of others It was this quality which brought him the full confidence of his colleagues, and when in 1919 Sir Francis Mowatt resigned the chairmanship of the finance committee of the Governing Body shortly before his death, there was no hesitation about the appointment of his successor Sir Otto Beit continued to hold this important post until his death, and though he was greatly handicapped in recent years by ill-health, he worked untiringly to further the interests of the College He interested himself not only in the government of the College, but also in the life of the students, many of whom are indebted to him for unobtrusive acts of kindness We have lost a great friend and a great benefactor

H T TIZARD

PROF C E MOSS

THE death on Nov 11 last of Prof C E Moss, at his home in Johannesburg, at the age of sixty, is a serious loss to South African botany and to systematic botany at large Charles Edward Moss was a native of Cheshire, the youngest child of a Nonconformist minister who settled at Halifax in 1874 He gained his early education at elementary schools in that town, eventually becoming a pupil teacher At the age of twenty-three he had a serious illness and his convalescence involved spending much time in the open air This led to a keen interest in field botany and close acquaintance with the local naturalists, who were at that time a very active body Moss thus became a competent field botanist before he was able, at twenty-five years of age, to go to the Yorkshire College, Leeds, and work for his degree as well as his teacher's certificate At Leeds he found Miall's teaching and outlook very acceptable, and in 1896, when the late Dr W G Smith went to Leeds as lecturer in botany, Moss was greatly attracted by the new method of studying and mapping plant communities in the field which had been inaugurated in Scotland by Smith's elder brother Robert

Moss took his degree in 1898 and collaborated with Smith in the first 'primary survey' of vegetation to be made in England (Leeds and Halifax district), published in the *Geographical Journal* in 1903 He also published several minor botanical studies in local journals After leaving Leeds he taught at a school in Bradford, and later at Bruton in Somerset, where he applied the new method to the local vegetation with conspicuously successful results In the Somerset paper, too, which was also published by the Royal Geographical Society (1907), he worked out a logical system of units of vegetation which he elaborated later in another publication (1910), and which was made the basis of the treatment adopted in "Types of British Vegetation" (1911) Moss was anxious to leave schoolmastering, and in 1902, at some financial sacrifice, he migrated to Manchester and lectured in biology at the Municipal Training College, at the same time improving his knowledge of general botany by attending honours lectures at the University

In 1904 the British Vegetation Committee was founded to facilitate the co-operation of the small band of active workers on the survey of British vegetation Moss was one of the original and certainly one of the most valuable members of the Committee His acute logical mind and his

increasingly critical knowledge of species were of the greatest use in accelerating the rapid advance in our knowledge of British vegetation which marked the first decade of the century While at Manchester he undertook a survey of the Peak district which gained him his D Sc degree and was published much later (in 1913) by the Cambridge University Press In 1907 Moss was invited to go to Cambridge as Curator of the University Herbarium, and gladly accepted the invitation, though again at some financial sacrifice He joined Emmanuel College as an advanced student and took his B A degree by research During the ten years he was at Cambridge he lectured in systematic botany, demonstrated to the elementary students, and was very active in field work

From about 1910 Moss turned more and more to critical systematic botany After publishing several excellent and illuminating critical papers on different small genera, he conceived the idea of a new British flora on a monumental scale This the University Press agreed to publish as the "Cambridge British Flora", and vol 2, dealing with the Amentiferæ and allied families, to which Moss had paid special attention, appeared in 1913 The outbreak of War, however, seriously compromised the financial prospects of this ambitious undertaking, and, together with other difficulties, led to the suspension of the work, only one other volume (vol 3) appearing, under the editorship of an old pupil, Mr A J Wilmott of the British Museum, after Moss had left England

In 1917 Moss was appointed to the professorship of botany at Johannesburg, and here he gradually developed a very living and flourishing department, which was becoming a centre of research on South African floristics At the same time Moss applied himself with characteristic energy and thoroughness to the task of becoming acquainted with the South African flora He found that the published and herbarium material was to a large extent untrustworthy, and he set himself to revise various groups, travelling widely for the purpose for he was never content until he had seen the species he studied in their native habitats He had published very little since he went to South Africa, but he had a large amount of material in hand Another five years would almost certainly have seen the appearance of so great a body of accurate systematic work as would have securely established his repute as a critical taxonomist of high rank

Moss was a man of singularly acute, logical, and independent mind With no adventitious advantages, he fought his way by sheer ability, hard work, and devotion to his subject, to a high place in the science After attaining one reputation as a pioneer ecologist, he was making another, no less distinguished, as a taxonomist, and only his untimely death has prevented its full fruition A G T

PROF FELIX LÖHNIS

BY the death at Leipzig on Dec 8 of Prof Felix Löhnis, the science of bacteriology has sustained a serious loss Löhnis was born in Dresden on Aug 3, 1874 After he left school and before he finally turned his attention to academic work he was engaged in practical agriculture for several years In 1901 he received the degree of Ph D from the University of Leipzig, and in 1905 he became responsible for the instruction and research in agricultural bacteriology in that University During the period 1905–1914 Löhnis's investigations did much to clarify the position of his subject The chief contributions of his department were concerned with methods, the seasonal variation in bacterial activities, the decomposition of calcium cyanamide, and nitrogen fixation This period in Lohnis's career was also notable for the publication of a manual of methods which has been translated into several languages, a text-book which is still the best work of its kind on the subject, and the well-known "Handbuch der landwirtschaftlichen Bakteriologie", which is the only comprehensive and critical review of the literature in existence In 1912 Löhnis had attained a position of such eminence among agricultural bacteriologists that the British Association extended to him an invitation to address Section M (Agriculture) at the Dundee meeting

In the spring of 1914 Löhnis was offered and accepted an appointment in the United States Department of Agriculture, and in 1923 he took over the direction of the Department's work on the bacteriology of soils Between 1914 and 1923 he devoted much of his time to researches on the life-cycles of the bacteria The results of this work, contained in a monograph published in 1921 and in other papers, are of a far reaching nature, challenging as they do the fundamental principle of monomorphism, upon which the science of bacteriology has been built Whether all Lohnis's views will be accorded general acceptance is still uncertain, but there is no doubt that his investigations on the life histories of bacteria will exert a profound influence upon the ultimate development of the science

In 1925 Lohnis returned to the University of Leipzig as professor of agricultural bacteriology and soil science, and in a very short time he had under his direction a volume of work which was probably greater than that undertaken by any other department of the kind in Europe The chief contributions of the later years are those which deal with the fermentative and other changes which take place in the making of the various types of farmyard manure and in the preservation of forage crops In 1929 Löhnis became editor of the *Zentralblatt für Bakteriologie*, Abt II, and a short time before his death he was at work upon a new edition of his "Handbuch"

Those who have had the privilege of working under Löhnis will always treasure the remembrance of his enthusiasm and inspired direction In the planning, conduct, and supervision of research he was unsurpassed, and his intuition frequently proved to be of quite an exceptional nature In such matters his extensive and accurate knowledge of the literature of his subject was of the utmost value It also enabled him to detect at once the rather frequent modern practice of

publishing, as new discoveries, already well established facts Of all such tendencies, as well as of work carried out in a perfunctory manner, he was most intolerant and did not hesitate to express his opinion in emphatic terms His later publications were often greatly condensed and consequently difficult to read As a result he has sometimes been misunderstood and has not always received the credit to which his work entitles him His contributions to science, however, have been outstanding and will yet cause his name to be placed among those of the pioneers in bacteriological work

DR P PINKERTON

PETER PINKERTON was born in Kilmarnock on Jan 8, 1870, and received his early education at the Academy there At the University of Glasgow he gained the degree of M A with highest honours in mathematics, and afterwards he studied for two years at the Royal College of Science, Dublin After a period of six years as mathematical master in Allan Glen's School, Glasgow, he was appointed head of the mathematical department of the Royal Academical Institution, Belfast, a position which he resigned after a short tenure to take up a similar one in George Watson's College, Edinburgh Sixteen years ago he was appointed Rector of the High School of Glasgow, and he discharged the varied and responsible duties of that post with marked success and increasing distinction until his death on Nov 22 last

Dr Pinkerton was a very great teacher He had an exceptionally alert mind and an unfailing sense of humour About a very clever student he once remarked, "He will make a poor, poor teacher, he never had a difficulty" His own outstanding success was largely due to his complete sympathy with all his pupils He appreciated the difficulties of the dull, as well as the eager curiosity of the brilliant

Under Dr Pinkerton's inspiration and guidance, marked developments took place in the High School of Glasgow The intellectual and social life was quickened, and the provision of splendid playing fields opened up a new era in athletics Quietly and unobtrusively he devoted all his powers of mind and heart to the welfare of the School in all its aspects, and its betterment was his constant aim

Dr Pinkerton was a prominent member of the Edinburgh Mathematical Society, and served as secretary, as president, and as first editor of *Mathematical Notes* He frequently contributed to the *Proceedings*, and was the author, in collaboration with the late Prof Gibson, of a book on the "Elements of Analytical Geometry" Throughout this volume old students have no difficulty in recognising his characteristic methods of treatment and exposition

The University of Glasgow, for which Dr Pinkerton acted as examiner for degrees in mathematics at various times, conferred on him the degree of D Sc in 1909 and of LL D a few months before his death

DR H BORNS

THE death of Dr Henry Borns on Dec 12 last, at the age of seventy-five years, removes a very familiar figure from the meeting-places of scientific societies in London Until the last year or two, when ill-health made his attendances not so regular, he was present at nearly every meeting concerned with physics or subjects related thereto Always one would find him busily reporting the proceedings (for many years he acted as reporter for *Engineering*) and anxious to supplement his notes by a talk with the lecturer and a perusal of the manuscript Although he was thus well known to the secretaries of the societies, few people seem to have known him intimately He seldom volunteered information about himself, and he probably led a rather lonely life apart from his meetings He was born in Austria, but must have come early in life to England, for he became a member of the British Association forty-eight years ago, attended the Montreal meeting in 1884, and missed very few meetings since that date He joined the Physical Society in 1895, and was an original member of the Faraday Society

Dr Borns in the course of his work acquired a wide knowledge of physical subjects and his reports displayed expert discrimination His notes were made without ordinary shorthand, in a curious abbreviated script, presumably legible to himself but a terror to his correspondents, for he used it in his letters also He was a kindly soul, always anxious to be of assistance to the secretaries with whom he came into contact, and punctual in keeping his promises for the return of manuscripts lent to him For half a century in a quiet way he served science well and faithfully, by giving it the best form of publicity—that based on accurate and well informed records His many scientific friends will miss him greatly

WE regret to announce the following deaths

Mr J H Emerton, an authority on American spiders and formerly secretary of the New England Federation of Natural History Societies, on Dec 5, aged eighty three years

M Henri Gall, a former president of the French Society of Civil Engineers and president of the Industrial Chemistry Society, aged sixty eight years

Prof Emile Gley, professor of general biology in the Collège de France, who was known for his work on the ductless glands, particularly the thyroid and parathyroid, aged seventy three years

Dr O P Hay, formerly of the Carnegie Institution of Washington, known for his researches in Pleistocene palæontology and as author of the "Catalog and Bibliography of the Fossil Vertebrates of North America", on Nov 2, aged eighty four years

Prof E W Hyde, formerly professor of mathematics at the University of Cincinnati and vice-president in 1891 of Section A of the American Association for the Advancement of Science, aged eighty seven years

Vice Admiral Sir Charles Royds, K B E, who served as first lieutenant of the *Discovery* in the British Antarctic Expedition of 1901–4, on Jan 5, aged fifty four years

News and Views

THE important announcement has just been made that in the near future there will be established in the vicinity of Toronto an astronomical observatory which will rank with the world's greatest institutions of this kind It will be erected by Mrs D A Dunlap and her son, D Moffat Dunlap, as a memorial to the late David A Dunlap, who died on Oct 29, 1924, and will be known as the David Dunlap Observatory Astronomy and geology were both favourite studies of Mr Dunlap, but the former had a peculiar attraction for him He was a keen student of the heavens, and always liked to share his knowledge with others This project has been under consideration for the last five years and will now be brought to completion In working out the plans, Mrs Dunlap has had the assistance of Prof C A Chant, head of the Department of Astronomy of the University of Toronto

THE outstanding feature of the David Dunlap Observatory will be a large reflecting telescope seventy four inches in diameter There is only one of greater aperture in the world, namely, that on Mount Wilson in California The instrument was ordered some time ago from the firm of Sir Howard Grubb, Parsons and Co, of Newcastle on Tyne It will be housed in a circular metal building, such construction being best for this purpose The observatory building will be a beautiful structure in the classic style It will be erected on a suitable site near Toronto, in the midst of a large acreage which will be converted into a park, to be known as the David Dunlap Park When the observatory is completed, it will be under the Department of Astronomy of the University of Toronto, while the park will be developed in a scientific way by the Faculty of Forestry The new institution will bring distinction to the University the city, the province, and indeed the whole Dominion It will be an enduring memorial to a worthy citizen

IN a recent leading article (see NATURE, Nov 22, 1930, p 797) we pointed out the urgent need for increased attention to the systematic study of the Indian peoples and cultures in view of the probable political conditions of the future Bearing on this, it may be mentioned that Lord Winterton, in the *Empire Review* for January, closes an article discussing the problems of form and organisation in the government of India, with which the Round Table Conference has been concerned, by very pertinent illustration of the extraordinary range of variation in the peoples whose destiny is being decided Discussion since the Conference opened has served to bring out even more clearly the fundamental importance, beneath the purely political problem, of questions of race, of religion, and of culture At the same time, letters to the Press, such as that from Mr Codrington which appeared in NATURE of Dec 13, 1930, p 919, and the correspondence in the *Observer* and elsewhere, while directing attention to such facilities as exist in England for Indian studies which are essential to the understanding of these questions, have emphasised their inadequacy

STRONG support for the views on the question of anthropological studies in India itself, which we ourselves expressed, may be drawn from the presidential address delivered in the Anthropological Section at the seventeenth Indian Science Congress held last year at Allahabad and now available in the recently published congressional proceedings (Calcutta Asiatic Society of Bengal, 1930 15 rupees) The president, the Rev P O Bodding, most urgently impressed upon his hearers the necessity for a record of the facts relating to custom, even the commonest facts of everyday life Admitting the attraction of theory, he pointed out that an unbiased and uncoloured record of the facts is an essential preliminary to study, and alone affords any certainty of permanent value Mr Bodding is primarily and indeed solely interested in the scientific aspect of the matter but he made use of a cogent argument in support of his plea, the force of which is equally, if not more, applicable in relation to the bearing of anthropological study upon the problems of administration In India to day, he urged, change in custom is taking place continuously and everywhere He quoted from his own long experience among the Santals, where, for example, their attitude of mind in marriage customs appears to have changed entirely, passing, it would seem, from an attitude of potential hostility to one of union with the 'parties of the other part', while in religion, it is now customary to find that at the celebration of a Hindu festival the greater number of the participants, and those who make the most noise, are Santals, officially classified as 'animists' It is obvious that if from the scientific point of view it is important that a record of the facts should be preserved at the earliest possible as well as at the later stages of development, it is no less important that the administrator should have an exact knowledge of the changes that are taking place and of their direction

A CURIOUS feature of the industrial situation is the pronounced shortage of administrators competent to direct and organise industry on the scale which the magnitude of modern industrial combines and their international relationships require Men of the requisite ability are not automatically produced by the present system On the contrary, authorities such as M Henri Fayol have pointed out that under the specialisation involved in rationalisation the departmental manager or executive rarely has the opportunity of gaining the wider experience which is essential in higher administrative duties It has been authoritatively estimated, moreover, that in the case of the managing director even of a highly technical organisation, the amount of technical ability essential is only 10 per cent as compared with 50 per cent of administrative ability, and even in the head of a technical department 35 per cent of administrative as compared with 30 per cent of technical ability is required Such factors accordingly present serious obstacles in the promotion or training of staff for promotion to the higher administrative positions Valuable work to remedy this state of affairs is being

done in Europe by the International Management Institute founded in 1927 by the XXth Century Fund, the International Labour Office, and the International Committee for Scientific Management This Institute has already made a number of important studies on the application of scientific management in special factories, in banking, and in railway undertakings, and is fast becoming a clearing house of world information and a focus of activity on all questions covered by the resolutions of the World Economic Conference

IN Great Britain the Institute of Industrial Administration is carrying out similar work, and claims to have united in a comprehensive view the principles underlying the various aspects of industrial administration It aims, further, at establishing industrial administration among the recognised professions, and with the further objects of education and the maintenance of high standards of skill and responsibility among its members, has modelled itself to some extent on the lines of established professional institutions In opening a public discussion on Dec 12, Mr A S Comyns Carr, president of the Institute, pointed out that modern competition calls for a higher standard of administration, to eliminate waste and reduce costs of production, as well as in the introduction of new methods, and this is true of all sizes of business undertakings and of marketing as well as of production Mr Comyns Carr believes that the foundations of the knowledge required can be laid by suitable reading and instruction, and that examination can test these foundations and the capacity for initiative and common sense Primarily, in its educational work, the Institute is an examining and not a teaching body Arrangements are now being made by educational authorities to provide instruction by lectures in some or all of the subjects of the Diploma of the Institute, and this work is supplemented by the formation of a Students' Society to provide reading courses at very moderate fees

ONE of the present Government's measures for assisting agriculture has been the Land Drainage Act of 1930. It would appear to be a popular subject with politicians and recent governments, when asked what they have done for agriculture, have generally been able to give good accounts of what they have done to encourage the drainage of agricultural land The cynic asks why this zeal for draining, when the land that is already drained cannot produce crops at a profit There has, however, been a definite need for the present Act, and Mr A T A Dobson has explained this and the provisions of the Act very clearly and concisely in a paper read recently at the Surveyors' Institution Rationalisation is a universally acclaimed palliative for our economic troubles to day Agriculture cannot expect to escape, nor does it deserve to This Act rationalises one thing in agriculture, the law of land drainage it is intended to produce order out of something approaching chaos Previously there was a large number of drainage districts under the jurisdiction of authorities of different types, and there was too much clashing of responsibilities and interests Large rivers were rarely dealt with satisfactorily The War years caused drainage works to fall badly into arrears In 1926 trouble arose in the Great Ouse district in the form of passive resistance to the payment of drainage rates A special Commission was set up in consequence, followed by a Royal Commission to investigate the whole question of the law of land drainage

THE present Land Drainage Act follows closely the recommendations of the Royal Commission, and most of Mr Dobson's paper is devoted to an explanation of its provisions The general effect is that there will be two classes of drainage authority the catchment board, responsible for all works on its main river, with supervisory jurisdiction over a wide area, and with considerable powers of raising revenue, and the ordinary drainage board, called within a catchment area an internal drainage board, responsible for the drainage of limited areas Mr Dobson then describes the methods of financing the drainage operations of these two types of authority, explains other points in the Act, and concludes by claiming that "the Act provides the necessary machinery for securing that, in future, all the waterways and drainage channels in England and Wales can be kept in a proper state of efficiency, including main rivers" If this proves to be the case, a very useful and necessary Act has been passed

REPRESENTATIVE exhibitions of British chemical plant are of infrequent occurrence Though the last one, held in 1926 in conjunction with the London meeting of the Society of Chemical Industry, was very successful, a favourable opportunity for repeating this venture has so far not occurred A unique opportunity for remedying this state of affairs and for bringing British chemical plant to the notice of the chemical and allied industries throughout the world will occur next July on the occasion of the jubilee celebrations of the Society of Chemical Industry The British Chemical Plant Manufacturers' Association has decided, in co operation with the Chemical Engineering Group of the Society, to stage an exhibition which will be open during the whole week of the celebrations, July 13–18 inclusive, at the Central Hall, Westminster The exhibiting area will be twice as great as in 1926 The exhibition will cover all types of plant, apparatus, instruments, constructional materials, and general equipment required by the chemical industry and the numerous other branches of industrial activity associated with it Only makers of British plant will be eligible to exhibit There will be a section devoted to the work of the various research associations and to the Department of Scientific and Industrial Research, this will be organised on non trade lines by the Chemical Engineering Group of the Society of Chemical Industry, and its object will be to demonstrate the important part which science plays in the development of British industry and in the control of the products Admission to the exhibition will be free, and invitations will be widely distributed to those who are interested in British chemical plant The public will also be admitted free on the Friday

afternoon and the Saturday Special steps will be taken to ensure the production of a fully classified catalogue, which will be supplied free either on admission or on application to the British Chemical Plant Manufacturers' Association Further information regarding the exhibition can be obtained from the office of the British Chemical Plant Manufacturers' Association, 166 Piccadilly, London, W 1

THE Newcastle upon Tyne Electric Supply Co and its associated companies supply an area exceeding 4000 square miles, extending from Scarborough to Alnwick and including York The power supplied is used for domestic purposes, mining shipbuilding engineering, and general manufacturing The system of supply is three phase alternating, at voltages ranging up to 20,000 Naturally the accurate metering of all this energy was a problem of great difficulty A full description of the difficulties and the methods by which they have been overcome is given in a paper read to the Institution of Electrical Engineers on Jan 2 by E Fawssett and G E Moore The records show that good meters need not be examined oftener than once a year Small meters are only examined once in every two years and very small meters once in every four years The meter readers use motor cars which carry the testing equipment including check meters Each car carries two testers each of whom must be able to drive the car and perform all the routine tests About forty cars are always at work, and the performances of the meters under a variety of conditions are tested the larger meters being subjected to more thorough tests It is found that the lower bearing of the meter disc which revolves on a vertical spindle is the most unsatisfactory part of the whole meter Oil is used to prevent rust and the pivot and the jewel are immersed in it Considering that electric meters are running sometimes for years at a stretch with a maximum inaccuracy of sometimes less than one per cent it will be seen to what a pitch of perfection manufacturers have developed them It is satisfactory to learn that the cost of the elaborate arrangements made to safeguard the revenue of the Newcastle company by accurate metering is less than the thousandth part of the revenue

IN 1914 the developments in the design of thermionic relays enabled a telephone cable to be laid across the United States from ocean to ocean Each relay has a filament from which electrons are liberated when it is heated by current from a battery The most desirable filament at present in use is that used in the circuits of the Bell Telephone System It consists of a platinum alloy the surface of which is coated with a mixture of barium oxide and strontium oxide A minute trace of barium in each filament permits the use of a much smaller amount of power for heating We learn from the *Bell Laboratories Record* for October that a quarter of a million telephone repeaters are in everyday use The amount of barium used for each filament is only about one sixth of a microgram For all the tubes in use the total amount of the barium effective in the emission of electrons is not more than the twentieth of a gram A clean tungsten filament required 35 watts for heating as compared with only 2 2 watts required for a filament coated with barium. Multiplying the quarter of a million tubes in use by the cost of the current taken from storage batteries, we see how the minute quantity of barium utilised in accordance with the methods found by fundamental research effects a great saving in the commercial working of the system Experiments are quoted that prove the remarkable fact that the electron current which is possible at any heating temperature from a single layer of barium atoms on a platinum wire is enormously greater than the current which could be obtained from a filament of either substance alone

SINCE 1926 there has been issued at Woods Hole a paper devoted to the work and workers at the Marine Biological Laboratory and the Bureau of Fisheries Laboratory With the increasing number of workers at Woods Hole the need for some such organ is apparent The *Collecting Net* as it is called is issued weekly during the summer months and contains besides items of local interest to workers short summaries of some of the research carried out at the laboratories each accompanied by a critical review A glance at last year s issues together with the directory of investigators emphasises how Woods Hole becomes during the summer months a great meeting ground for biological workers who form a unique community some hundreds strong But this centre of biology is to be even further enriched by the addition of the largest oceanographic institution in the world The issue of the *Collecting Net* for Aug 30 of last year contains plans and details of the proposed Woods Hole Oceanographic Institution the construction of which has already begun The Institution has been endowed by the Rockefeller Foundation with grants of 1 000 000 dollars to finance the buildings and equipment and 1 000 000 dollars as a permanent endowment fund An additional working grant of 50 000 dollars a year has been promised for a period of ten years The Institution is under the directorship of Dr Henry B Bigelow and is to be a four storied building with about fifty rooms and three or four large laboratories for student investigators From here an ocean going research vessel will operate in the Atlantic The ship 105 feet long at the water line and with a displacement of about 380 tons will be a two master with ketch rigging fitted with an auxiliary Diesel engine Work has already started on this vessel which is being built at Copenhagen The Institution will possess a resident staff of eight or ten workers who will remain at Woods Hole all the year round It is hoped that building will be completed so that the laboratory will be able to open its doors next summer

ON Jan 6 a film on The Sirex Woodwasp and its Parasites was shown privately at the London Pavilion This film is the first attempt at applying the talking film to biological research The wood wasp is responsible for serious havoc to timber, especially in New Zealand This film is to form the first of a series dealing with the habits of the more important Empire forest insects It is to be in

corporated also in the new "Secrets of Nature" series of films, which will be produced this year. Many excellent silent films of scientific subjects, especially relating to natural history, are already available, and the use of the sound film for like purposes is therefore to be welcomed. Educational films are shown in various theatres throughout the country, comprising biology, chemistry, other branches of science, history, and so forth. They are, in some cases, used to make up a complete programme. These, however, are of the popular or very elementary type and, where they from a complete programme, are meant for school children. On the other hand the illustration of a biological or any other scientific subject which one supposes will be of a specialised nature, by means of the sound film, is a different problem. It is too much to expect many members of the general public to pay for performances made up of films of such a nature, so, at the most the films could only be used for filling up a programme of entertainment. The value of the film would thus be seriously diminished. The best use that could be made of such films, the production of which should be encouraged, is for presentation before societies and academic and research institutions. However, much was suggested in this direction with regard to the silent film, but little has yet been done, probably for financial reasons. Nevertheless, the project has a possible future, and its development does not rest so much with production and photography as in securing a sufficient demand to justify producers undertaking the costs involved in making films of this nature.

ON the afternoon of Dec. 18, at the Lister Institute of Preventive Medicine, a large company, consisting of the staff and other research workers, past and present, met in the library of the Institute to offer parting gifts to Sir Charles Martin and Prof. Arthur Harden on the eve of their retirement. Prof. J. C. G. Ledingham, who is succeeding Sir Charles Martin as director, presided, and referred to the fact that only a few years ago a very similar gathering assembled to celebrate the conferment of knighthood on Sir Charles Martin by presenting him with his portrait. Sir Charles had directed the activities of the Institute for twenty-seven years. His highly successful administration might justly be attributed in the first instance, to the great charm of his personality, and secondly, to his tact, his business ability, and the surprising catholicity of his scientific interests. Prof. Harden had served the Institute for thirty-three years and, as biochemist in chief, during that period made his department an important centre of biochemical research. Only a year ago he was awarded a Nobel prize in chemistry for his work on fermentation. While the departure of Sir Charles Martin and Prof. Harden would mean a severe loss to the Institute's forces, the traditions they had set would long remain a potent source of inspiration to their successors. On behalf of the many subscribers at home and abroad, Miss Harriette Chick presented to Sir Charles and Lady Martin a silver coffee service, designed and executed by Mr. Philip Alexander of Walberswick, Suffolk, while Miss Muriel Robertson unveiled and presented to Prof. Harden his portrait in oils by Mr. Neville Lewis. Sir Charles and Lady Martin sailed on Jan. 2 for Cape Town, en route to Australia where Sir Charles will take charge of the Division of Animal Nutrition of the Commonwealth Council for Scientific and Industrial Research for at least two years.

IN a paper reprinted from the *Transactions* of the Indian Philosophical Congress (1927), Mr. J. Walker Tomb declares that 'time' is used in two senses, metaphysical and mathematical. The former is the duration or continuance of personality, depending upon consciousness and memory. The latter, in his opinion, is the duration of matter, and he considers that the definitions of Aristotle, Newton, Einstein, and Eddington are quite wrong. Moreover, "the relativists ... have built upon this misconception a bewildering philosophy which dethrones reason". To support this view, passages are quoted concerning bodies travelling with the velocity of light. (This, of course, is a case in which the equations cease to hold. As Einstein says, "Lumen is a fraud".) It is interesting to compare these views with Sir Arthur Eddington's opinions. In an interview reported by Mr. J. W. N. Sullivan (*Observer*, Dec. 21, 1930), he said: "We must remember that the notion of time, as it occurs in science, is a mere abstraction. The notion of time is, I believe, an abstraction from the dynamic nature of consciousness. Consciousness is essentially dynamic, and the 'time' of science is a most imperfect representation of this quality." The drawing together of science and philosophy is much hindered by the tendency of each side to misunderstand the other.

FOURTEEN of the leading French publishing firms which specialise in the production of technological literature have combined to produce a "Bibliographie des livres français d'Industrie et de Technologie". The lines of the 'Catalogue of British Scientific and Technical Books' of the British Science Guild have been closely followed, with the following difference, namely, that books published in 1929–30 precede the General Catalogue for 1919–30, which forms the bulk of the work. Entries in Part 1 are annotated, those in Part 2 are not. The name and subject indexes include both sections. Hence there is some danger of confusion, and the writer of the prefatory note wisely counsels the user of the Bibliography to consult both sections "en cas de recherche". An annual supplement to the bibliography is promised with a consolidated edition every third year. The classification and indexing of the entries have been carried out in a workmanlike manner, and we have no doubt that the bibliography will prove a useful guide in the selection of French technological books in all parts of the world.

THE north-east of Scotland has many points of contact for the archæologist, the historian, and the naturalist, and each of these, as well as the general reader, will find articles of interest in the latest issue of the *Deeside Field*. Selecting from a wide variety of topics, we mention only the Rev. Dr. Walker's

account of "Some Memorable Naturalists of the North East" He recalls the accomplishments of William MacGillivray, naturalist and ornithologist, George Dickie, botanist, James Nicol, the geologist, who first saw a glimmer of light in the upheavals of the North-west Highlands, of George Sim, taxidermist and naturalist, and Thomas Edward, of Banff, who spent his boyhood in Aberdeen But there are others, for no account could be complete which omitted the name of the Army surgeon, Dr A Leith Adams, who, in addition to writing popular accounts of his natural history observations in India and Egypt, became an authority on fossil elephants

PROF WILLIAM KING GREGORY has been elected president of the Galton Society for the Study of the Origin and Evolution of Man, New York, and Mr Frederick Osborn has been elected secretary-treasurer

A MEETING to inaugurate a British Society of Motion Picture Engineers will be held at the rooms of the Royal Photographic Society, 35 Russell Square, on Monday, Jan 19, at 7 P M A draft constitution has been drawn up by the provisional committee, the secretary of which is Mr Leslie Eveleigh, Gaisford House, Gaisford Street, Kentish Town

THE following advisory committee has been appointed for the purpose of advising the Minister of Health on the practical application of modern advances in the knowledge of nutrition Prof Major Greenwood (chairman), Prof E P Cathcart, Sir F Gowland Hopkins, Miss Jessie Lindsay, Prof E Mellanby, and Prof V H Mottram The members will hold office until Dec 31, 1933, and will be eligible for reappointment The secretary to the committee will be Mr F R Hudson, of the Ministry of Health

THE Council of the Royal Astronomical Society has awarded the gold medal to Prof W de Sitter, director of the Observatory of Leyden, for his theoretical investigations on the orbits of the satellites of Jupiter and his contributions to the theory of relativity Prof de Sitter has also been invited to deliver this year's George Darwin Lecture The Council has awarded a Jackson Gwilt medal and gift to Mr Clyde W Tombaugh, of Lowell Observatory, Flagstaff, Arizona, in recognition of his discovery of the extra-Neptunian planet, Pluto

ON Tuesday next, Jan 20, at 5 15, Mr J W T Walsh will deliver the first of a course of three lectures at the Royal Institution on the art of illumination, on Thursday, Jan 22, at the same hour, Prof H Dingle begins a course of three lectures on the nature of physical science The opening Friday evening discourse of the year will be given by Sir William Bragg, on "The Scattering of Light", on Jan 23, Mr J M Keynes will deliver the Friday evening discourse on Feb 6, on the mechanics of the trade slump

THE Council of the Royal College of Surgeons of England has appointed Mr J H Thompson, lecturer in physiology at King's College, London, to the research scholarship endowed by the late Lord Melchett The subject to which Mr Thompson proposes to devote himself is the influence of the parathyroid bodies on growth His research will be carried out in the new laboratories of the Royal College of Surgeons and also in the physiological department of King's College Mr Wilfred Trotter has been appointed Hunterian Orator of the Royal College of Surgeons for 1932

AT the meeting of the Grand Council of the British Empire Cancer Campaign, held on Jan 12, arrangements were approved in connexion with the Garton Prize of £500 and Gold Medal, which is to be awarded to the person or persons submitting the best original dissertation on "The Early Diagnosis of Cancer" by December 1931 It was also announced that the subject, "The Biological Effects and Mode of Action of Radiations upon Malignant and other Cells", had been chosen for the second Garton Prize and Medal, the dissertations for which must be received by December 1933

THE following appointments have recently been made by the Secretary of State for the Colonies in the colonial agricultural and forestry services Mr G H Gethin Jones to be soil chemist, Kenya, Mr H Evans, to be physiological botanist, Mauritius, Mr M H French, to be biological chemist, animal nutrition research, Tanganyika Territory, Mr R J A W Lever, to be entomologist British Solomon Islands, Mr C O Flemmich, to be assistant conservator of forests Federated Malay States, Mr T E D Vigne, to be assistant conservator of forests Nigeria, Mr C E Duff, to be assistant conservator of forests, Northern Rhodesia, Mr C H Holmes, to be assistant conservator of forests, Ceylon

AT the annual meeting of the Association of British Zoologists, held on Saturday, Jan 10, in the rooms of the Zoological Society of London, with Prof E B Poulton in the chair, the morning session was devoted to discussions as to whether zoologists should accept fees for lectures and expert advice, and on the future of zoological collecting In the afternoon it was moved "that training for applied zoology must be based upon a broad general zoological foundation", the three principal speakers being Dr W T Calman, who dealt with museum work, Dr E S Russell, with fisheries work, and Prof J W Munro, with entomological work The Association has only recently been formed and this was its first meeting, although, for seven years previously, there has been an annual meeting of British zoologists to discuss matters affecting the interests of the science

DR FRANK CONRAD, of the Westinghouse Electric and Manufacturing Co, Pittsburgh, has been awarded the Edison Medal, the highest award of the electrical engineers in the United States, for pioneering work in radio telephone transmission before the days of broadcasting In addition to his developments in radio communication, Dr Conrad has made important contributions to alternating current work and arc lamp design, he has been in the employ of the Westinghouse Co since 1890, and is now assistant chief engineer The Edison Medal was founded by associates and friends of Thomas A Edison and is

given annually for "meritorious achievement in electrical science, electrical engineering, or the electrical arts", by a committee of the American Institute of Electrical Engineers

MESSRS W and G Foyle, Ltd, 119 Charing Cross Road, W C 2, have just circulated a catalogue of their No 7 department, containing the titles of books, both second hand and new, relating to most branches of technology and applied science Being carefully classified, the catalogue should be of service to many readers The list is obtainable upon application

APPLICATIONS are invited for the following appointments, on or before the dates mentioned — A research scholar in mental diseases under the Joint Board of Research for Mental Diseases of the University of Birmingham and the City Mental Hospital Committee — E Eyles, Hon Secretary, Council House, Birmingham (Jan 24). An advisory research entomologist at the Seale-Hayne Agricultural College, for the South-West Province—The Principal, Seale-Hayne Agricultural College, Newton Abbot, Devon (Feb 8) A physicist or engineer to carry out researches and standardisation in wireless telegraphy and telephony, and a physicist to carry out researches in optics, each under the National Research Council of Canada—The Secretary Treasurer, National Research Council, Ottawa, Canada

Our Astronomical Column

The Near Approach of Eros — Prof H N Russell gives, in the *Scientific American* for January, a clear account of the methods being employed for using the present approach of Eros for obtaining improved values of the solar parallax and the mass of the moon He estimates that fully ten years will be needed for a full discussion of the measures but there is one source of delay that he has not considered Several observatories have been co operating during the past six or seven years in obtaining accurate places of selected stars near the planet s track But the track diverges appreciably from the predicted one, to the extent of 1 minute of time in R A at the nearest approach This makes some of the selected stars unsuitable, as being too far from the planet It will be necessary to select others on the opposite side of the planet to take their place, and these will need to be carefully observed One precaution that was not considered in 1901 is now being taken The spectra of the stars have been examined, and those that differ markedly in type from Eros (the spectral type of which resembles that of the sun) will be rejected, owing to the different amount of their refraction by the earth's atmosphere The article notes that the opposition of 1938, though inferior to the present one, will be much better than that of 1901, which was the best since the planet was discovered in 1898 1968 will be about equal to 1938, and the next really favourable oppositions will be in 1975 and 2012

Axial Rotation of Stars —In the *Astrophysical Journal*, vol 72, p 1, Dr O Struve discusses the spectroscopic evidence for the existence of rapidly rotating stars The occurrence of rapid rotations is assumed in many astronomical theories, such as the fission theory of binaries, but so far there has been no direct evidence that they are anything but rare exceptions Dr Struve shows that broad, shallow absorption lines are caused by axial rotation The broadening exhibits the proportionality to wave length required by the Doppler effect, and the line contours agree with the theoretical shapes for rapidly rotating stars There is also a correlation of line width with period and amplitude in spectroscopic binaries Two stars (α Virginis and η Ursæ majoris) are treated in detail, and the evidence suggests the existence of an evolutionary transition between close spectroscopic binaries and rapidly rotating single stars, though the direction of such transition is not established by the observations

Old Eclipses of Jupiter's Satellites —Some of the secular variations of the elements of Jupiter's satellites are so slow that they cannot be satisfactorily determined from recent observations alone All the calculators of tables of the satellites have made some investigations of this kind, that which Prof W de Sitter has lately published in *Annals of Leiden Observatory*, vol 16, part 4, is one of the most complete The earliest observations used are those of Wargentin, beginning in 1668, the extensive list prepared by Delambre in preparation for the construction of his tables has also been used The systematic errors of the observations have been investigated, they are very considerable, but in spite of these a very marked improvement in the secular variations of the elements of satellite III has been obtained in this discussion The improvement is less noticeable in the cases of satellites I and II, as their changes are more rapid and can be determined from the modern observations

Prof de Sitter is much interested in the question of the changes of the earth's rate of rotation, and includes a discussion of the evidence afforded by Jupiter's satellites, the old observations do not add much weight to the determination He considers that the amount of uncertainty of his curve derived from all sources is not more than 5 seconds at the date 1670, the uncertainty from the satellites at the date 1750 is fully 10 seconds

A New Catalogue of the Naked-eye Stars —The Yale University Observatory has published a useful catalogue of 9110 stars, edited by Prof F Schlesinger It contains practically all the stars down to mag 6 5 and a few fainter ones The reference numbers in Boss P G C and in the northern and southern Durchmusterungs are given The positions are given only to the nearest time second in R A and the nearest minute of declination The Proper Motions have been revised and, where possible, are given to the third decimal of a second of arc, those in R A are expressed in great circle The spectral type, parallax, and radial velocity are given, where they are known There is also a column of remarks, which includes notes of companions, of variation of light, or of radial velocity There is also a table for reduction to galactic co ordinates, and one giving the new constellation boundaries as fixed by a committee appointed by the I A U The following systematic corrections have been applied to the proper motions of the P G C

In R A $+0\ 00021^s \quad -0\ 00015^s \sin$ R A $\tan$ Decl
In Decl $-0\ 0023'' \cos$ R A

A bad misprint on page 4 of the introduction should be corrected The R A of the galactic pole is given as $18^h\ 40^m$, it should be $12^h\ 40^m$

Research Items.

Totemism of the Wik-munkan Tribe, Gulf of Carpentaria.—Miss Ursula McConnel continues her study of the Wik-munkan tribes in *Oceania*, vol. 1, pt. 2. Each clan has a number of totems of varying importance which are common to all members of the clan. These are mostly drawn from objects of utility round which daily interest centres, and in the case of natural supplies, from those found in the locality, thus reflecting their economic interests. Thus, totems of the coastal tribes include dugong, sea turtle, sharks, and other fish; 'thunder' which heralds the north-west season, 'high-tide' which brings food, and a 'small bird' which is supposed to guard the fishing operations of a clan; bark canoes and spears, necessary to the success of the hunt; pelicans, geese, pigeons, flying-fox, and so forth. The Wik-mean tribes include milk-wood trees, porcupines, and swamp turtle, all belonging to the Wik-mean country. The totems of other tribes are similarly differentiated according to their economic resources. Dangerous and disagreeable objects also figure in the lists—for example, crocodiles and flies; and objects of social significance such as fire, which is not only useful, but is also the centre of social life as well as the means of disposing of the dead; the bull roarer, and the shooting star or meteor, which is supposed to signify the death of a relative. The 'baby', 'sweetheart', and 'ghost' totems reflect the chief phases of human life—birth, mating, and death. Personal names are derived from the characteristics of the clan totems, or reflect their social value to the clan, sometimes their occupations in association with the totem. Thus, men take their names from the spear handle, women from the fishing net and dilly-bag which they make and use. Women of the dilly bag totem take a special pride in their string work, as if they were mistresses of the art. Or again, women may be called after the crab which they hunt, while men are called after the barramundi fish which they spear. Where totems are animals, women often take their names from the female of the species and its feminine functions.

Dimensions of Flint Implements.—The study of flint implements has in the past been confined to a consideration of the characteristic features displayed by the implements in virtue of the special uses for which they were designed and of the technique employed in making them. Prof. A. S. Barnes (*Proc. Prehistoric Soc. East Anglia*, vol. 6, pt. 2) applies to groups of 100 implements, selected at random, the mathematical methods developed by Galton, Karl Pearson, and others dealing with the characteristics of a crowd or large assemblage of objects, the dimensions used being those of maximum length, breadth, and thickness. It is shown that the 'medians' for length, breadth, and thickness are approximately constant for a given industry and can be used to describe the dimensional characteristics of that industry with precision. Prof. Barnes combines these medians into a single expression which he terms the 'index figure'. The index figure consists of two parts, a whole number and a fraction. The whole number is the median for length, the numerator of the fraction is the product of the medians for breadth and thickness, and the denominator is the median for thickness. Thus an index figure of 61·7 $\frac{544}{13 \cdot 6}$ means that for a group of 100 implements from the industry in question the median length is 61·7 mm., the median cross-sectional area is 544 mm.^{2}, and the thickness is 13·6 mm. It may be urged that the size of the blocks of flint available will influence the size of the implements made from them. From recent measurements made by the author it appears that this is so only to a limited extent, except in rare cases where the raw material available is exceptionally small. For example, the index figure for the Mousterian of Acheulean traditions at Le Moustier itself is 62·2 [illegible], whereas the index figure for implements of the same culture at Combe Capelle, where the raw material is much larger and more abundant than at Le Moustier, is 66 [illegible]. The various methods of measuring closeness of packing of the measures are also described and discussed. The statistical methods employed enable a precise statement to be made of the dimensions of a group of implements in a simple manner, and form a useful adjunct to morphological considerations in determining to which cultural series a group of implements belongs. There are a number of diagrams illustrating the results.

Placentation of the Cony.—Dr. George B. Wislocki gives an account of observations made on the placentation of the cony (*Hyrax capensis*), in vol. 21 of *Contributions to Embryology*, issued by the Carnegie Institution of Washington. The hyrax is usually regarded as having its nearest allies in elephants and hoofed vertebrates, but Dr. Wislocki finds that its placenta differs in structural type from that of the ungulates and resembles that of the insectivores. He also concludes that in its placentation hyrax has many resemblances to that of the much discussed aberrant primate form, *Tarsius*. That there should be a considerable resemblance between the form of placentation of these two aberrant mammals is very remarkable, for they appear to represent different mammalian phyla. Nevertheless both have a disc-shaped placenta which is provided with a dense massive covering of invasive trophoblast. The trophoblast remains poorly vascularised by vessels of fœtal origin. Dr. Wislocki is inclined to regard the form of placentation found in *Hyrax* and *Tarsius* as primitive, while the diffuse placentation of ungulates he would look upon as a later and more fully specialised form. One rejoices to see, in these volumes of *Contributions*, that Mr. Carnegie's benefaction is serving so well the needs of those engaged in embryological research. Under the directorship of Dr. George Streeter a very high ideal has been established amongst the contributors to this valuable publication.

Culturing Insects for Virus Research.—One of the difficulties to be encountered in the rearing of insects for experimental tests of their transmission of virus diseases in plants, is the necessity for maintaining stocks of them free from any possibility of infection. In the *Annals of Applied Biology*, vol. 17, August 1930, Dr. Marion A. Hamilton describes a method for keeping pure and uninfected cultures of aphides and kindred small insects in cages of a special type. These are constructed of a metal framework covered with cellophane and roofed over by means of fine bolting silk. Such cages have the advantage of being portable and freely permeable to light and air. They are, at the same time, proof against the accidental entry of minute forms of insect life, that are commonly so difficult to exclude in experimental work. She further describes a method of rearing aphides apart from their plant hosts. Specially constructed glass capsules were used to contain the feeding medium; these were closed by a membrane of fish skin and then inverted. By this means the aphides (*Myzus persicæ*) were induced to insert their stylets through the fish skin and feed upon artificial media, plant extracts or dyes. Cultured in this way, a certain number lived for six days, and in one case seven days. A longer period of survival may be possible if more suitable media be found.

Genes affecting Chromosome Behaviour—In connexion with the intensive studies of the genetics and cytology of maize, now being carried on at Cornell University, a new genetic factor has been discovered (G W Beadle, *Memoir* 129, Cornell Univ Agric Expt Station), which causes asynapsis, or a failure of the chromosomes to pair in meiosis A similar factor has already been found by Blakeslee in *Datura*, and Gowen has described a condition in *Drosophila* in which there is complete absence of crossing over All these mutations are inherited as simple Mendelian recessives In *Matthiola* a strain with long and another with short heterotypic chromosomes exist, the difference being ascribed to a single Mendelian gene These cases are of special interest in that in each an alteration in the shape or synaptic behaviour of all the chromosomes is due to a single germinal change, which affects the cytological characters but not the phenotypic appearance of the organism, except in so far as it results in sterility The asynaptic strain of maize is almost completely sterile both in pollen and ovules In the pollen meiosis there is no pairing of threads, and in diakinesis 20 univalent chromosomes appear instead of 10 bivalents That the normal attraction between all the chromosome elements should thus be completely inhibited by a single genetic factor is a remarkable fact If such a factor appeared in a species of plant which also reproduced vegetatively, it would lead to a condition of pollen sterility without previous crossing These asynaptic plants, like haploids, occasionally produce viable pollen grains with the unreduced number of chromosomes

Studies of Lactose-fermenting Yeasts and of Moulds of Milk, Cream, and Butter—M Grimes and J Doherty in the routine examination of milk, cream, and butter have isolated two types of yeasts which ferment lactose with gas formation and produce slight acidity in milk (*Sci Proc Roy Dub Soc*, vol 19, No 20, May 1929, p 261) In both types the cells are ovoid, measuring 3 6 μ in length, neither forms spores They appear to be identical with *Torula lactosa*, Harrison, and *T cremoris*, Hammer, isolated from cheese and from cream respectively M Grimes, V C E Kennelly, and H A Cummins in a study of mould fungi found in butter isolated twenty nine species (*ibid*, vol 19, No 47, October, 1930, p 549) Several of the species, while closely resembling, did not altogether conform to type species, and it is suggested that Irish fungi as a result of insularity have developed characters of their own In an examination of moulds from butter, V C E Kennelly and M Grimes report the isolation of a new species of *Paecilomyces* (*ibid*, vol 19, No 44, September 1930, p 513) It is a coremia forming species, with pink spores, it clots milk and partially liquefies gelatin, with evolution of gas and an acid reaction It is named *Paecilomyces hibernicum*

Methods for Fruit Disease Survey—"Epidemic Diseases of Fruit Trees in Illinois, 1922–1928", is the somewhat modest title of a *Bulletin* (Art 3) in vol 18 of the State of Illinois (Department of Registration and Education) Division of the Natural History Survey The paper is by L R Tehon and G L Stout, and these workers summarise the results of six years' work on an intensive survey of fruit tree diseases in their area They have visited a very large number of orchards, making full records, which include accounts of spray treatments and their efficacy, times of application, notes on phenology, and the time and severity of disease incidence It appears from the collected work that pomaceous fruits are usually opposite, in their reaction to a fungus epidemic, to drupaceous fruits, but the main value of the report lies not in the particular conclusions that emerge and which apply to local conditions, but in the careful and exhaustive attempts which have been made to standardise the observations which form the basis for such a survey

The Great Whin Sill—A very important paper by Dr J A Smythe, recording the results of many years' work in the field and laboratory on the group of intrusions known as the Whin Sill, appears in the *Transactions of the Natural History Society of Northumberland, Durham, and Newcastle upon-Tyne*, vol 7, pt 1, pp 16 150 Samples from practically every fresh exposure have been collected, 2950 in all, and two average analyses and ten others, covering the whole area, are presented A large number of specific gravity determinations are recorded These reveal a progressive variation on a regional scale and additional analyses of alkalis (26), FeO (31), and H_2O and CO_2 (28) indicate that the variation is related to slight differences in the composition of the original magma A chemical study of the chief minerals and of micropegmatite makes it possible to calculate the mineral composition of each of the rocks analysed The results agree very closely with the micrometric measurements previously made by Holmes It is shown that the titaniferous black ores cannot be regarded as mixtures of magnetite and ilmenite Analyses are given of seven exceptional rocks ranging through leucocratic varieties to a felsitic type, and these with the normal rocks give a variation diagram closely parallel to that of the normal magma series of Mull A noteworthy feature is the record of five occurrences (all analysed) of fine grained basaltic rocks intrusive into the Whin Sill Only one of the dykes (the Hampeth) associated with the Whin Sill is given detailed treatment, since these were dealt with in a recent paper by Holmes and Harwood (*Min Mag*, p 493, 1928) Alterations due to chloritisation, pectolitisation, vein solutions, and weathering have been closely investigated with the aid of ten new analyses The problem of assimilation is very thoroughly examined, the chemical evidence is entirely unfavourable, and a convincing explanation involving the mode of emplacement is given to account for the puzzling field evidence which drove Clough to face the possibility that assimilation had taken place The paper is one that will provide data for discussion for many years Apart perhaps from the work of Brammall and Harwood on Dartmoor, no limited group of intrusions has ever been so thoroughly investigated

A Low Aurora and its Effect on a Radio Receiver—Though no photographic determination of the height of auroræ has ever yet yielded reliable values below 80 km, cases of auroræ coming much lower, even to the ground, are occasionally reported Mr A C Cummings, Room 1111, 180 Varrick Street, New York, sends us such a report—which also has other unusual features—of an aurora witnessed by his brother at Norwood, Ontario, Canada, early in the winter of 1929–30 He observed that his radio set was 'dead', though the valves were alight and the aerial and ground wires were connected, no reason for the absolute quietness of the set was apparent Looking out, he saw that a bright aurora was in progress, on going outside to get a better view he found, "to his astonishment, that a curtain of streamers extended from the sky to the ground and completely surrounded the house but at a distance of several feet" The curtain was many coloured and unsteady, its scintillations being accompanied by "visible sparking" and by "snapping sounds"

Thermionic Emission—The October number of *Reviews of Modern Physics* contains an article on thermionic emission, by Dr S Dushman In this he has summarised the existing literature on the subject, with, however, special reference to the work of the last ten years This has proceeded partly on the lines of the determination of the emission constants of pure substances, but perhaps most characteristically in the development of composite emitting surfaces, both of the well known type of the thoriated filament, in which monomolecular films of one substance are formed on a base of another, and of the oxide type, coated filaments can now be prepared which will operate in arc tubes, as well as in highly exhausted containers Theoretically, the outlook has naturally been changed by the advent of the new quantum mechanics, which accounts qualitatively for almost all of the phenomena in question, and quantitatively for many of them Dr Dushman remarks with justice that it is difficult at the present time to realise that only sixteen years ago the very existence of a pure electron emission from incandescent solids was questioned by many physicists of good repute

Operating a Loud Speaker without High Tension Circuit—We have received an interesting communication from Dr S R Khastgir, of University College, Colombo One of his students, P U Ratnatunga, has invented a very simple method of operating a loud speaker by means of a diode valve without using a high tension circuit It seems to us that his method is of practical importance It would be useful, for example, in connexion with portable sets, as the usual high tension battery adds appreciably to the weight It would also be useful in connexion with aeroplanes and in military manœuvres The receiver Mr Ratnatunga uses is a single valve receiver which has a diode valve One side of the filament of the diode is directly connected to the earthed point of a tuned aerial circuit The anode of the diode is inductively coupled to the tuned circuit by means of a coil with which the loud speaker is in series, and then goes back to the filament The loud speaker operates at nearly full volume when working Good results were obtained even with an indoor aerial The reception took place about four miles from the receiving station, the power of which was 1 75 kilowatts The resistance of the loud speaker was 2000 ohms and the current through it was only 0 1 of a milliampere When a high tension battery was used the current was 6 milliamperes An ordinary Cossor valve was employed

Dielectric Properties of Ionised Gases—An investigation of the dielectric properties of ionised air described by E V Appleton and E C Childs in the December number of the *Philosophical Magazine* provides a very satisfactory demonstration of some of the properties of the Heaviside layer which are required to account for its action on wireless waves The air was ionised in a glow-discharge at low pressure, and auxiliary electrodes inserted in the discharge tube to form the condenser of an oscillatory circuit The two chief results concern the dielectric constant of the ionised gas, which, for small concentrations of ions, was found to be less than unity, in accord with theory, and the effect of a superposed magnetic field, which, when appropriately oriented and of the right magnitude, was shown to produce a type of resonant spiral motion of the free electrons of the discharge with the same frequency as the oscillations in the condenser circuit In addition, however, Prof Appleton and Mr Childs have found that the thin positive ion sheaths, which form on the condenser plates in the gas when this is heavily ionised, alter completely the capacity of the condenser, the ionised gas between the sheaths acts as a conductor, and the effective capacity is simply that of the two sheaths in series The alteration in the capacity of these sheaths with change in the steady potential applied to the plates follows the law required by Langmuir's theory of exploring electrodes It is of interest to find that the reduction of the dielectric constant below unity was probably detected by the late Prof Barton immediately after the publication of Eccles's theory of the ionic refraction of wireless waves in 1912

Conductivities of Salts in Ethyl Alcohol—The *Journal of the Chemical Society* for November contains some results of measurements of electrical conductivities of uni univalent salts in ethyl alcohol by Murray Rust and Hartley Lithium chloride, nitrate and perchlorate, and sodium and silver perchlorates were investigated The fall in conductivity is proportional to the square root of the equivalent concentration in accordance with the theory of strong electrolytes A comparison of the slopes of the equivalent conductivity $-\sqrt{c}$ curves with the theoretical values calculated from the Debye Huckel-Onsager equation shows that the experimental slope is greater than the theoretical, the percentage deviations from theory varying between 10 and 130 per cent This would be expected if there were any ionic association The range of concentration used was $N/500$ $N/10,000$ The perchlorate ion has a greater mobility than other anions in ethyl alcohol

Activity Coefficients of Salts—There are cases where the activity coefficients of salts deviate considerably from the expected values, and in two papers in the *Journal of the Chemical Society* for November, C W Davies shows that these can be explained on the assumption of incomplete dissociation of the salts concerned When allowance is made for the incomplete dissociation of the added salts, the activity coefficients found for thallous iodate from solubility measurements are no longer abnormal The activity coefficient becomes independent of the nature of the added salt at concentrations, with uni univalent salts, below 0 1 ionic strength The activity coefficient of thallous iodate in the most dilute solutions is expressed by the equation $\log f = A\sqrt{\mu}$, but the value of A is smaller than the value given by Debye and Huckel's theory It appears that this result is general, and also that A may vary from salt to salt Large deviations from the Debye Huckel theory with salts, which have been described as 'electric type' effects, or 'unsymmetrical valency type' effects, are considered to be due wholly to incomplete dissociation of the salts concerned

Keto-Enol Equilibrium—Although the keto enol tautomerism of aceto acetic ester and some of its alkyl derivatives has been previously studied, it is clear that interesting results would be obtained by studying the effect of substituents in the α position, and some experiments are described by Posl and Michalek in the November number of the *Journal of the American Chemical Society* which deal with this problem The α phenyl ester was prepared and was found to contain 28 6 per cent of the enol form The percentages of enol in esters substituted in the α position by methyl, ethyl, and benzyl are 4 1, 0, and 3 4 respectively The values obtained from molecular refractions were entirely different from those with bromine titrations (for example, more than 100 per cent enol was found by the first method as compared with 28 6 per cent by the second), and the chemical method is preferred

Twenty-first Annual Exhibition of the Physical and Optical Societies.

THE twenty first annual exhibition of the Physical and Optical Societies was opened by Sir Arthur Eddington, president of the Physical Society, on Tuesday, Jan 6 Sir Arthur commented on the growth of the exhibition since its inception in 1905, and spoke of the mutual debt of the scientific worker and the instrument maker, saying that progress is making them more and more interdependent All types of apparatus for physical and optical work could be seen at the exhibition, and everyone should find something of particular interest to himself Sir Frank Smith proposed a vote of thanks, and this was seconded by Mr H T Tizard, Rector of the Imperial College, where the exhibition was housed

Electricity has steadily and rapidly taken its place at the foundations of physical science, and one has only to imagine the great reduction which would be effected on removing all electrical instruments to realise the truth of this fact The task of making a selection of interesting items for this article would then become decidedly simplified An interesting feature of this year's exhibition was the wide use made of photoelectric cells Several different kinds were on view, and one of copper oxide on copper, shown by the Westinghouse Brake and Saxby Signal Co, Ltd, operating a relay, merits special comment The Mullard Wireless Service Co, Ltd, was using a photoelectric cell to count the number of visitors to its stand, a beam of light being interrupted by each person as he approached The exhibits of the Gramophone Co, Ltd (H M V), Research Laboratories included a demonstration of the sensitivity of its own cell with a commercial potassium cell The former is of cæsium and of the same type as used in the television apparatus, unlike the copper oxide cell, it is most sensitive to red light An interesting method of measuring the sensitivity of a photoelectric cell by using it to control the output of a 'thyratron' was demonstrated by the British Thomson Houston Co, Ltd The current through the valve was used to drive a direct current motor the speed of which depended on the light falling on the cell, and a loud speaker emitted a note of a frequency dependent on the speed of the motor A photoelectric outfit shown by Messrs Bellingham and Stanley, Ltd, is worthy of mention It is suitable for the photometry of light sources or general spectrometric investigations Provision is made for the variation of the voltage on the cell as well as that on the electrometer plates, and particular care is taken to guard against the interference of external electrical disturbances

The Research Section of the exhibition has always attracted a great deal of well deserved attention, and has expanded considerably since it came into being only a few years ago There is little chance here of being called upon to admire an imposing box with knobs and other protuberances which the writer personally suspects of being either empty or filled with unwanted spare parts Perhaps a hint to exhibitors may not be out of place here Let all apparatus be uncovered on these occasions, even if protection is necessary in general use The physicist loves to see the wheels go round To return to the subject undoubtedly the most popular item in this section was the demonstration of television arranged by the Gramophone Co Ltd (H M V), Research Laboratories During the whole exhibition a crowd was waiting to see what further progress had been made in making the Arabian Nights become fact The definition of the image is good and the colour is also attractive Cinematograph pictures were scanned at the transmitter in five sections of thirty lines each, a lens drum being used to traverse a succession of images over five scanning apertures, and the received image was thrown on to a screen about two feet square The picture was built up of 150 scanning lines and was composed of 15,000 picture elements The frequency needed to give such detail, scanning at 12 times a second, is 23,000 cycles Among the fifteen demonstrations arranged in this section by the National Physical Laboratory, selecting any one for special comment is not easy The Radio Research Board was using a resonant wavemeter circuit to show the existence of side bands when a radio frequency oscillation is modulated by an audio frequency oscillation Messrs L F G Simmons and H C H Townend were demonstrating an interesting method of examining the air flow past models by heating the air in horizontal layers with hot wires The changes in refractive index of the air were used to trace the shape of the flow lines round the body in a shadowgraph Apparatus shown by Messrs F H Schofield and J A Hall was some of that used in establishing the absolute scale of temperature from − 183° C upwards, and included a platinum resistance thermometer, platinum thermocouple, and optical pyrometer Dr Ezer Griffiths had on view a multiple thermo element type hygrometer for distant reading which can be used in a ship's hold An apparatus for measuring the flow through flues was demonstrated by the Gas, Light, and Coke Co (Research and Training Section) The temperature at various points is observed and from the temperature gradient the rate of flow deduced A surprising fact is that the temperature across a section is far from uniform Since the flow of gases is turbulent, this is rather unexpected and opens the field for further work on the subject The Rothamsted Experimental Station showed a bridge for studying the water in soils and the nature of the association of the two, by passing an alternating current and noting the phase angle between this and the electromotive force Not all the water is available for plant life, and vegetation may wither in quite damp soil if the water present is combined with the soil An exhibit illustrating phase-change in tuned circuits, due to the British Thomson Houston Co, Ltd, is worthy of note A fixed primary coil formed the inductance of an oscillating circuit, and a swinging secondary coil was arranged so that the coupling between the two coils was periodically varied As the secondary vibrated the circuits passed through the resonance point and there were alternating attracting and repulsing forces due to sudden phase change The position of the pendulum at which the phase jump occurred was different for the two directions of movement, and this caused a series of impulses which maintained the motion

The Trade Section of the exhibition had many examples of good workmanship, and the optical instruments—especially epidiascopes shown by Messrs Carl Zeiss (London), Ltd, and Messrs W Edwards and Co—may be mentioned in particular Messrs Edwards also demonstrated several kinds of vacuum pumps, one of which—the 'Hypervac' rotary oil pump—will produce a pressure so low as 0 00005 mm The Cambridge Instrument Co, Ltd, exhibited many new instruments, those for use in geophysical surveying being of special interest, and described in Mr Lancaster Jones's discourse on Jan 7 The eight pages in the programme describing these instruments are worth studying The Leakey Harper drawing machine lent by Sir Arthur Keith may also be mentioned In addition to the instruments specified in the programme, Messrs Adam Hilger,

Ltd., showed a Fabry-Perot etalon with variable separation This is a beautifully made apparatus The plates are supported on invar in order to reduce temperature effects to a minimum during long exposures The instrument is suitable for measuring wave lengths in terms of a standard and observing fine structure in the longer wave lengths of the spectrum The Munsell Colour Books, intended to form the basis of a system of colour specification, and X ray gratings prepared in the laboratories of Prof M Siegbahn, were on view, as well as an all metal quartz spectrograph Of special interest to teachers was the astronomical model designed by Mr W Wilson and exhibited by Messrs A Gallenkamp and Co, Ltd, which demonstrates the motion of the earth, moon, and sun Each separate movement can be shown alone and the bodies can be made to perform hypothetical motions This should prove particularly valuable for educational purposes, since the reasons for day and night and seasons will be understood at once on seeing movements which do not produce them Both the M O Valve Co, Ltd, and the Mullard Wireless Service Co, Ltd, had a large selection of transmitting, rectifying, and modulating thermionic valves The M O Valve Co, Ltd, was demonstrating an assembly operation in which the supports for the inside of a valve were bent to the required shape by one movement of a handle

In the section for apprentices and learners started last year some good workmanship was on view In Class A (Craftsmanship) first prizes were awarded to T E Bayley (under eighteen years) of Marconi's Wireless Telegraph Co, Ltd, for a signalling relay, and to H G Freshwater, of Messrs H Tinsley and Co, for a vibrating galvanometer suspension This competitor also obtained the Finsbury prize In Class B (Draughtsmanship), first prizes were taken by W G Hill (under eighteen years), of Messrs H Hughes and Son, Ltd, for a periscope wind gauge bearing plate, and by E G Mansfield, of the General Electric Co, Ltd (Research Laboratories), for a controller for a motor operated rheostat It is to be hoped that this section will continue to grow as time goes on, since the importance of good instruments to the physicist cannot be over estimated

Two discourses were delivered in the large physics lecture theatre, both extremely interesting and very well attended The first, by Mr E Lancaster Jones, was entitled "Searching for Minerals with Scientific Instruments" Mr Lancaster Jones described the four methods used in locating salt deposits, oil, and other minerals, and mentioned the fact that all the instruments which he had in the room were—with only one exception—of British manufacture The four types of instrument used are gravitational, magnetic seismic, and electrical In the first of these methods the instrument measures the value of gravity at different points, and from the variation from normal a mound of denser material than the surrounding earth can be easily located Salt is generally discovered in this way, and its discovery is important, since oil usually occurs with it In the second method the horizontal intensity of the earth's magnetic field is measured, and the existence of magnetic veins disclosed The third method is very interesting An explosion is made at one point, and three sound waves travel to the recording instrument one through the air, one just beneath the ground, and one penetrates the surface as far as a layer of material of different density below ground and then travels along the top of this layer The velocities of sound in air and in the two substances are known, the times of arrival of the waves are recorded by the seismograph and, with the distance of the explosion, all the necessary data for finding the position of the mineral deposit are available The fourth method consists in tracing out lines of equal electrical potential between two electrodes across which an alternating current is passing These lines have a curved shape when copper or similar material exists below the surface The lecture was illustrated by experiments and slides

On Thursday, when the exhibition was open free to the general public, Sir Gilbert Walker gave an interesting account of "Physics in Sport" Sir Gilbert said that the tendency to separate applied mathematics from the happenings of everyday life was to be deplored, and then proceeded to make his audience agree with this statement by giving an explanation of the behaviour of balls He went on to give some idea of the principles involved in such sports as curling, spear throwing, and boomerang throwing The discourse was illustrated by a selection of slides and experiments, the strange behaviour of a coin when rolled on a billiard table causing much amusement

Many hours can be spent at an exhibition of this kind and another visit will still reveal something fresh The secretary is to be congratulated on the success of his organisation The amount of time and thought devoted to making a success of these occasions is scarcely ever realised by those who enjoy its fruits E M COLLINS

Annual Meeting of the Science Masters' Association

THE thirty first annual meeting of the Science Masters' Association was held at the University Edgbaston, Birmingham, on Jan 6 9 The meeting opened during one of the worst fogs on record, but in spite of this more than two hundred members and guests, including the Lord Mayor (Alderman Saunders), were able to find their way to the dinner and the presidential address Altogether more than four hundred members attended the meetings The University buildings are admirably adapted for the purposes of such a conference, and the staffs of the various departments of pure and applied science arranged a very fine series of demonstrations in the laboratories The exhibition of apparatus and books was held in the spacious drawing office, which is an ideal room for the purpose

The presidential address was given by Sir Charles Grant Robertson, Vice Chancellor of the University, who referred to the fact that boys and girls and the young university graduate and teacher of to day fail to realise the immense revolution that has taken place in the world of thought and education during the last fifty years In that period there has been a scientific renaissance comparable in the quality and scope of its range to the humanistic renaissance of the fifteenth and sixteenth centuries The result is that the monopoly of the classical humanists has been overthrown and smashed to pieces, resulting in the admission of other subjects into the school curriculum Sir Charles went on to say that, "confronted with the modern curriculum, Huxley would have insisted that the number of subjects taught is far too large and must be drastically reduced, and for the simple reason that the identification of education with the acquisition of information is an indictable misdemeanour" He (Sir Charles) was profoundly impressed with the ability of undergraduates in the faculties of science, but he often found that they were lacking in general culture Personally he would like to see the training in science continued for every boy

and girl up to the age when they left school, even if it meant for the specialist in humanistic studies some diminution in the school time allotted to the specialist subjects, just as he wanted to see the humanistic culture continued for the specialist in science. In reference to science scholarships, he would like these to be determined by the joint action of teachers in both schools and universities.

In the course of an address on "A Finite Universe?" the Bishop of Birmingham said that over-confident dogmatism during the nineteenth century produced a reaction which has resulted in a spirit of agnosticism in religion. In the present century this has spread to science, so that, at any rate in their better moments, science teachers are none of them dogmatic, not even the youngest of them. It is now recognised that the bases of our knowledge are probabilities, and these to-day threaten to become the ultimates of the physicist. Absolute truth is beyond us, and superstition is the refuge of fools. We shall be wise men if, knowing our ignorance, we search honestly that our understandings may be enlarged, and if, in our search, we never forget that man's intellectual and spiritual faculties are his supreme endowment. On first reflection we feel that the universe must be infinite in extent. Progress as to our understanding of space is due to the mathematician rather than to the metaphysician. Dr. Barnes referred to the following words of Gauss, written in 1824 in regard to what is now known as non-Euclidean geometry: "I think, in spite of the meaningless word-wisdom of the metaphysicians, that we know too little ... about the real meaning of space, to stamp anything as absolutely impossible because it appears unnatural to us." He went on to contrast the basic principles of Euclidean and non-Euclidean geometry and the deductions from each as to the properties of space, saying that it is highly probable that our space is curved and not flat, although at present, possibly owing to the limitations of our minds, we cannot get a concrete picture of what this means. In order to test the validity of this conclusion, mathematicians can devise experiments on the nature of the radiation from distant nebulæ, and the tests so far have indicated that the universe is finite and yet unbounded. He referred to Lemaître's theory of an expanding universe, which has gained the sympathy of astronomers because it seems to offer an explanation of the surprising and perplexing fact that the spiral nebulæ in the depths of space appear to be receding from us with velocities of the order of a thousand miles a second. In conclusion he said that, like Clifford, who was the first man in England to appreciate the significance of Riemann's researches, he found relief from the dreary infinities of flat space in the consoling hope that, after all, the universe may be finite.

A discussion on general science was opened by the chairman, Mr. Fairbrother, of The Cedars School, Leighton Buzzard, who said that general science was proposed by the Association in 1916 as a remedy for what was then called neglect of science. There is a danger that general science should be interpreted as that vague and indefinite type which leads to a nodding acquaintance with many topics of science but to a thorough knowledge of none. Mere snippets are not what the apostles of general science mean to develop. Their aim is to humanise science, to regard man as the central theme of the universe, and to show how man has bent the forces of Nature to his will and how he has made new substances by causing naturally occurring substances and their derivatives to act on one another. General science should cover the whole field of science. Not only should chemistry and physics form an essential part, but also astronomy, physical geography, and elementary biology should be given a place. The teachers of the various branches should be specialists in their own subjects, but the syllabus should be so arranged as to admit of close correlation between one section and another. It must always be remembered that good syllabuses do not necessarily mean good general science, the essence of which lies not so much in the syllabus as in the interpretation of it. Success or failure very largely depends on the outlook of the teacher. It has been suggested that examining bodies do not yet recognise the claims of general science, or give it the dignity of the usual science subjects; but surely that is a matter for the teachers themselves to settle. Let them create the demand and the examining bodies will supply the papers.

The discussion which followed was stimulating and instructive, member after member giving an account of his own course in general science and testifying to the interest aroused in the boys, who are often inspired to continue their studies to greater depths in their own time.

Prof. F. W. Burstall initiated a discussion on "The Science Education of a Boy up to the Age of Eighteen". He said that boys of eighteen who come up to the university have a competent knowledge of science; they can express themselves in clear English and have a fair knowledge of other humanistic studies. When we consider average boys who do not reach university standard, we must divide them into two sections: up to about fourteen and from fourteen to eighteen. Prof. Burstall considers that the young boy can be taught only through his memory, which is the reason why Latin and Greek can be taught him with a considerable degree of success. His view is that the only science taught at this stage should be what is known as Nature study—the description in simple words of the ordinary phenomena of Nature as he observes it in his everyday life. Like all simple subjects, this requires a born teacher to teach it properly. At fourteen the boy's mind is sufficiently developed to enable some science to be taught. Science consists solely of experiment, observation, and deduction, and is therefore by no means a new subject. It has been the study of humanity from the earliest days, when prehistoric man experimented on boring a hole through a flint, and it has been carried on by successive stages to produce our present civilisation. The boy up to fourteen is a young animal who delights in exercising his muscles, who is full of impish mischief and a disinclination to use his mind for any purpose of abstract reasoning. At the same time, he is curious to know how everything works and also the reasons for all the changes he observes in Nature. Prof. Burstall suggested that school science is attractive to the average boy because it gratifies his desire to make something or to change a substance. He urged that the boy should have an outlet for showing his own individuality. Boys differ so much that to attempt to find a curriculum to fit them all is bound to fail. Boys who are stupid in school are only so because they have never had a chance of displaying their faculties. He said that not too much emphasis should be placed on examinations, which, dealing as they do almost entirely with questions of fact, offer a premium to a boy with a good memory and a rapid power of assimilation, but are detrimental to the boy whose mind works slowly.

During the discussion which followed, Prof. H. E. Armstrong expressed his surprise and delight with the discussions he had heard. He was glad to observe that general science is taught in so many schools and that the movement is gaining ground. He disagreed

with Prof Burstall in regard to the boy up to fourteen, up to that age Prof Armstrong considers the boy to be intelligent—it is afterwards that his faculties become blunted

Mr Cameron, Director of Education for Oxford City, gave an account of the work of the Commission on Educational and Cultural Films At the request of the Commission, the Science Masters' Association has already appointed a sub committee to view and criticise films on scientific subjects, and two of those passed by this committee, "The Life of a Plant' and 'The Mechanism of a Motor Car", were shown to a crowded meeting The Association unanimously decided to give the Commission financial support

Mr J Young, in the course of a lecture on "The Lunar Landscape", showed many beautiful slides from photographs taken by his students, he outlined the research which is in progress on the nature and features of the moon's surface

Prof A W Nash gave an address on "The Work of the Physicist and Chemist in the Petroleum Industry", which emphasised the value of applied science There are only two Departments of Oil Technology in the country, one at Birmingham and the other at the Imperial College of Science in London These work in the closest correlation, each tackling different aspects of the petroleum problem

Prof W N Haworth lectured on "Complex Molecular Structures", and Prof Munro Fox showed a series of biological experiments suitable for schools

E N

University and Educational Intelligence.

LONDON —The following doctorates have been awarded *D Sc Degree in Biochemistry* on G F Marrian (University College) for a thesis entitled "The Chemistry of the Oestrin producing Hormone" (*Biochem Jour*, 1929–30) *D Sc Degree in Geology* on R G Hudson (University College) for a thesis entitled "The Lower Carboniferous (Dinantian) of the Craven Reef Belt" (*Proc Geol Assoc* 1930) *D Sc Degree in Physiology* on P Eggleton (University College) for a thesis entitled "The Significance of Creatine Phosphoric Acid in the Mechanism of Muscular Contraction" (*Jour Physiol*, Oct 1930) *D Sc Degree in Statistics* on J O Irwin (University College) for a thesis entitled "Researches in the Theory of Sampling" (*Biometrika*, 1927, *Metron*, 1930)

LIVINGSTONE COLLEGE, Leyton, E 10, which gives courses of instruction to missionaries in the elements of medicine, has issued the annual report and statement of accounts for the year 1929–30 Many former students testify to the value of the instruction they received at the College Income for the year has more than balanced expenditure, and the accumulated deficit has been reduced The deficit, however, still amounts to £758, and structural repairs and replacement of worn out equipment, deferred from year to year have now become urgent A sum of £800 is required to put things in order, and donations are asked for, and may be sent to the Principal, Dr Tom Jays

TEACHER TRAINING principles and methods have been exhaustively investigated during the past two years by a special committee of the Teachers' Training Syndicate of the University of Cambridge The resultant recommendations, recently adopted by the University, emphasise the importance of practical work and of guarding against the tendency of courses in the theory of teaching to produce doctrinaires with but little aptitude for dealing with the ordinary problems of school life It is interesting in this connexion to read the article published in the November issue of *School Life* on "Training Teachers on the Job" This expounds the principles on which the University of North Carolina bases its preference for 'in service' training as compared with training conducted wholly or mainly within a college of education, and describes some of the methods in use A staff of itinerant instructors is employed exclusively on weekly circuits, one day being given by an instructor each week to the members of his classes employed in each of the instructional centres in his circuit He observes throughout each morning all phases of their work and in the afternoon meets them for instruction, which his observations enable him to adapt to individual and group needs While admitting that some courses, such, for example, as those in the history of education or the physiology of the nervous system, can probably be conducted more effectively in residence in the university college of education, the rest—methods and materials in the various subjects, curriculum construction, investigation of educational problems, individual differences, educational measurements, diagnosis and treatment of failures, and the psychology of learning—can it is claimed be given with much greater immediate effect and permanence when taught by the 'in service' method

THE British Broadcasting Corporation has secured the services of many men and women who are eminent specialists in the worlds of art, science, economics, languages, philosophy, and so on, for its several series of broadcast talks from January to April of this year Judging from the pamphlet published in connexion with these series radical changes in the composition of each series have been made For example, the series of talks on "Marriage Past and Present" consists of five lectures by Prof B Malinowski and Dr R Briffault They will take the form of a debate, Prof Malinowski giving the first talk on "The Present Crisis in Marriage and the Historical Background" The second will be given by Dr Briffault Then will follow three talks in the form of a discussion between Prof Malinowski and Dr Briffault, concluding with a recapitulatory talk entitled "What can we learn from all this?" by Prof Malinowski Such a series has much to commend it, but one drawback is its actual seriate form which demands regular attention to such talks—and this is often impossible—if full value is to be obtained from them There are three or four series of talks with a scientific bias, which will be given by single lecturers Mr L F Gibbon is to talk on "Commerce the Peacemaker", Prof A E Heath on "Thinking Ahead", and Prof W Cramp on "Faraday and his Contemporaries" This last is clearly chosen because this year marks the centenary of Faraday's discovery The other series of scientific interest are to take a still different form Each talk in the series will be given by a different person One series, 'What is Science?" seems to have no common basis, the reason for putting them in one group seems to be that the listener is invited to co operate with the speaker in making investigations This is an experiment in what the B B C refers to as "co operative science" Such an attempt is deserving of commendation, but its value may be lessened by the fact that it is based upon the belief that science is now so professional and associated with such forbidding technique that the amateur scientific worker has almost disappeared and with him the journeyman's interest in science However this may be, the B B C is to be congratulated on its attempts to stimulate general interest in science by its varied and original programme

Societies and Academies.

LONDON

Linnean Society, Jan 8 —**E J Salisbury** A study of *Ranunculus parviflorus* L, with special reference to its morphology and ecology The floral structure has been studied in its entirety in 725 flowers, and in a considerably larger number with respect to special features The most frequent number of parts in the flower as a whole is 26 (222 examples) This, with other observations, leads to the conclusion that the total number of parts is a number one less than a multiple of three The structure of the sepals and their variation indicates their origin from leaves, and thus the sepal is the equivalent of the leaf base The staminodal nature of the petals is clearly indicated The petals attain maturity after the stamens, which may be associated with their, phylogenetically, more recent origin The structures of various tissues all suggest a plant of damp rather than dry habitats This is in conformity with the 'atlantic' type of distribution of the species and its southern habitats Experimental cultures show that the species does not grow so well on dry sandy or calcareous soils as on moist loam

PARIS

Academy of Sciences, Dec 1 —The president announced the death of René Blondlot, *Correspondant* for the Section of General Physics —**P Villard** The reduction of the oxygen compounds of phosphorus by hydrogen Phosphoric anhydride and hydrogen commence to react at 700° C, and at about 900° C both red and yellow phosphorus can be collected Phosphorus is similarly produced by the action of hydrogen upon sodium, barium, and calcium pyrophosphates —**J Costantin and P Lebard** Experimental cultures of healthy and degenerated potatoes in the mountains and in the plains The experiments described once more prove the difficulty of procuring healthy tubers working at random and without method Seed potatoes raised in the mountains will propagate disease if the pathological state is not taken into account The superiority, if it exists, will be shown only if healthy varieties are used —Jakob Eriksson was elected *Correspondant* for the Section of Rural Economy in succession to the late M Neumann —**Bertrand Gambier** Anallagmatic invariants of three circles —**Robert Forrer and A Hoffmann** The splitting up of the Curie points of nickel The observations described can be interpreted by assuming the existence of two ferromagnetic substances in nickel each with its own Curie point —**Lucien Amy** The examination of a metal for foreign elements by spectrum analysis The modification proposed gives a marked increase in strength to the lines of magnesium, calcium, and carbon **R Barthélemy** A system of television, including, in particular, an automatic arrangement for synchronisation and setting in phase —**E Darmois and J Cessac** Study of solutions of tartrates in fused calcium chloride, $CaCl_2 + 6H_2O$ —**Mme P Curie** The relation between the emission of long range α rays and of γ rays The theoretical explanation suggested, although not in good agreement with experiment, may still be of service New researches are required to determine more accurately the range of the α rays and the existence and intensity of the groups of γ rays intervening —**J and J F Thovert** The utilisation of photo electric cells with glass envelope for researches on radiations of very short wave length The glass is coated with a layer of vaseline, gelatine, or collodion with which is incorporated a fluorescent substance —**P Chevenard and A Portevin** The mechanism of the reheating of martensite —**F Bourion and E Rouyer** The cryoscopic study of paraldehyde in solutions of sodium chloride and barium chloride —**A Mavrodin** The action of phenyl magnesium bromide on ethyl diethylcyanacetate —**R Brunschwig and L Jacqué** The formation of gums in petrols The colour acquired by a benzol on keeping is not a measure of the gum formation Gum is formed in benzol by the combined action of light and air —**Octave Mengel** Movements of the Quaternary in the Mediterranean Pyrenees —**P Gavaudan** Some vital observations concerning the evolution of the vacuome during spermatogenesis of the Characeæ —**N Lœwenthal** The evolution of the white blood corpuscles in vertebrates —**René Fabre and Henri Simonnet** Contribution to the study of the phenomena of oxido reduction Researches on beer yeast The influence of desiccation The experiments with beer yeast confirm those made with hepatic tissue the hydrosulphide derivatives can only be freed from combination as the result of a traumatism which causes the death of the cell —**Mlle Catherine Veil and Adalbert Van Bogaert** The two heart chronaxies measured selectively according to the direction of the electric current —**H Laugier, W Libersohn, and B Néoussikine** The variations of chronaxy as a function of the position in man —**Régnier and Lespes** The existence of a summer generation in the pilgrim locust, *Schistocerca gregaria* —**L Mercier** A new type of cancer of the lung in mice Heredity and grafting —**E Brumpt** Latent parasitism of *Ixodiphagus caucurtei* in gorged larvæ and fasting nymphs of various Ixodes (*Ixodes ricinus* and *Rhipicephalus sanguineus*) —**Georges Fontes and Lucien Thivolle** Tryptophane and histidine are hæmatogen amino acids —**Mlle S Mouchet** The formation of the non pedunculated spermatophores of the decapod Crustaceans —**C N Dawydoff** The true nature of *Dogelia malayana* —**Mlle Odette Tuzet** The fertilisation of the silica sponge *Cliona viridis* —**Maurice Marie Janot and Jean Laurin** Bulbs of *Allium cepa* and hyperglycæmia

CAPE TOWN

Royal Society of South Africa, Oct 15 —**E Reuning** A contribution to the geology of the western edge of Bushmanland There were morphological conditions on the edge of the plateau immediately anterior to the time of the melting Dwyka ice which, after the subsequent denudation of the Karroo sediments, were re established, and they still form the major part of the morphological structure of this region From the time of the oldest determined sediment of the post Kimberlite period, a practically complete chain of events up to the present is recognisable —**S H Haughton** On a collection of fossil frogs from the clays at Banke, Namaqualand The specimens are part of a large collection discovered in the shales encountered by Dr Reuning when sinking a shaft on the so called 'Arnot' pipe on Banke, Namaqualand There are a number of almost complete skeletons of a fossil frog, to which the name *Eoxenopoides reuningi* is given, A series of stages is described which strengthens the conclusions drawn from living Anura that the whole urostyle is the result of the fusion of a number of vertebræ Evidence as to the age of the clays containing the fossils is almost entirely circumstantial, they must be at least early Tertiary and may be contemporaneous with, or slightly later than, the Dinosaur bearing beds of Kangnas, 40 miles to the north —**M R Levyns** Note on some recent experiments on the germinating capacity of Rhenoster seed Germination tests have been carried out annually since 1925 It has been shown previously that seed which refuses to germinate at the time of shedding

will germinate well a year later Temperatures during the resting period may play an important part in regulating capacity of the seed for germination —**E Reuning** The Pomona quartzite and oyster horizon on the west coast of South Africa north of the Olifants River mouth Ancient phyllites are planed off and covered by a series of deposits which consist of a fossiliferous grit with shark's teeth at the base, followed by a strongly silicified sand and grit passing up into calcified and partly silicified clays Lying unconformably upon these sands and clays—the equivalent of the Pomona quartzite—are marine deposits, divided into the Main Oyster horizon below and the *Donax rogersi* beds above Above these is a terrestrial cover of sand, which has been formed in a discontinuous cycle —**T Levitt** A report on the Cape Flats femur A detailed study of the thigh bone found in a sand quarry on the Cape Flats, in the same circumstances as a skull which has proved to be decidedly primitive The femur shows primitive human and even simian characters, and belonged to an individual appreciably different from any of the existing human types in Africa and definitely low in the human scale This finding corresponds to that arrived at independently for the skull

CRACOW

Polish Academy of Science and Letters, Oct 6 —**Georges Bouligand** Some applications of the theory of ensembles to infinitesimal geometry —**Ladislas Natanson** Certain theorems associated with Fermat's principle —**W Swietoslawski** A differential boiling point apparatus furnished with a fractionating column and its application This apparatus is specially applicable to the study of the purity of liquids either pure substances or azeotropic and eutectic mixtures, and has been designed to handle small quantities of liquids The determination of the amount of water present in an acetone-carbon disulphide azeotropic mixture is given as an example —**J Kozak** and **L Musial** The action of hydantoin on o nitrobenzaldehyde —**J Nowak** Remarks on the age of the magmatic rocks of the uncovered layers of Cieszyn —**J Zerndt** Megaspores arising from a layer situated at a depth of a hundred metres at Libiąż (Stephanian) **Z Grodzinski** The development of the blood vessels in the fore foot of the tortoise (*Emys orbicularis*)

Diary of Societies

FRIDAY, JANUARY 16

ROYAL SOCIETY OF MEDICINE (Balneology and Climatology Section) (Clinical Meeting at Red Cross Clinic for Rheumatism Peto Place N W 1), at 5

PHYSICAL SOCIETY (at Imperial College of Science) at 5 —Dr T L Ibbs and Dr K E Grew The Influence of Low Temperatures on the Thermal Diffusion Effect —Dr J H Vincent Further Experiments on Magnetostriction Oscillators at Radio Frequencies.—S. Butterworth and F D Smith The Equivalent Circuit of the Magnetostriction Oscillator —Dr L C Martin The Theory of the Microscope

BRITISH INSTITUTE OF RADIOLOGY (at 32 Welbeck Street) at 5 —Medical Meeting

SOCIETY OF CHEMICAL INDUSTRY (Liverpool Section) (at University, Liverpool) at 6 —*Prof* G T Morgan Organic Syntheses facilitated by Pressure (Hurter Memorial Lecture).

NORTH-EAST COAST INSTITUTION OF ENGINEERS AND SHIPBUILDERS (at Mining Institute Newcastle-upon Tyne), at 6 —S F Dorey Some Factors influencing the Sizes of Crankshafts for Double acting Diesel Engines

COKE OVEN MANAGERS ASSOCIATION (Midland Section) (at University, Leeds), at 6 30 —H J Hodsman Coke for Domestic Fires

INSTITUTION OF MECHANICAL ENGINEERS (Informal Meeting), at 7 — Major W Gregson and others Discussion on Steam versus Oil Engine in the Mercantile Marine

INSTITUTION OF LOCOMOTIVE ENGINEERS (Manchester Centre) (at Manchester Literary and Philosophical Society, Manchester), at 7 —T H Sanders Locomotive Suspension and its Influence on Derailments.

ROYAL PHOTOGRAPHIC SOCIETY OF GREAT BRITAIN (Pictorial Group, Informal Meeting), at 7

SOCIETY OF CHEMICAL INDUSTRY (Newcastle Section) (at Armstrong College), at 7 30 —Dr B. Moore Fused Silica in Industry

JUNIOR INSTITUTION OF ENGINEERS (Informal Meeting), at 7 30.—K W Willans Some Problems Surrounding the Reorganisation of an Engineering Works.

ROYAL SOCIETY OF MEDICINE (Obstetrics and Gynæcology Section) (jointly with Tuberculosis Association), at 8 —Discussion The Management of Pregnancy Parturition and the Puerperium in Tuberculous Women Openers Dr G Marshall and Dr M Hiley (Tuberculosis Association) A Bourne and L. C Rivett (Obstetrics and Gynæcology Section)

ROYAL SOCIETY OF MEDICINE (Electro Therapeutics Section), at 8.30 — Dr G Grant Allan Radiology of the Heart.

SOCIETY OF DYERS AND COLOURISTS (London Section).—J T Holden Researches on the Laundering of Fabrics

SATURDAY, JANUARY 17

ROYAL INSTITUTION OF GREAT BRITAIN, at 3 —Sir E Denison Ross Persian Art and Literature (2) The People, the Country, and the Poetry of Persia

HULL ASSOCIATION OF ENGINEERS (at Municipal Technical College, Hull), at 7 15 —R L Quertier Air Compressors

MONDAY, JANUARY 19

VICTORIA INSTITUTE (at Central Buildings, Westminster), at 4.30 —Rev Dr W M Christie The Renaissance of Hebrew

ROYAL GEOGRAPHICAL SOCIETY at 5 —New Types of Survey Instruments —Instr Capt. Baker The 45° Prismatic Astrolabe —Major G Cheetham The Tavistock Theodolite

ROYAL COLLEGE OF SURGEONS OF ENGLAND, at 5 —Prof V Bonney The Results and Technique of Myomectomy

BRITISH SOCIETY OF MOTION PICTURE ENGINEERS (at Royal Photographic Society), at 7 —Mr Lance Photo Electric Cells

INSTITUTION OF ELECTRICAL ENGINEERS (South Midland Centre) (at University of Birmingham), at 7 —S G Brown Loud-Speakers since their Conception, with Gramophone Pick ups and Wireless Recording Apparatus

INSTITUTION OF ELECTRICAL ENGINEERS (Mersey and North Wales (Liverpool) Centre) (at Liverpool University) at 7 —E M Payne The Radio—Gramophone Pick up

ROYAL INSTITUTE OF BRITISH ARCHITECTS at 8 30 —Presentation of London Architecture Medal 1929, and Medals and Prizes, 1931

HUNTERIAN SOCIETY OF LONDON (at Apothecaries Hall) at 9 —Dr A Lorand The Problem of Rejuvenation (Hunterian Lecture).

SOCIETY OF CHEMICAL INDUSTRY (Yorkshire Section) (Jointly with Institute of Chemistry—Leeds Area Section) (at Leeds) —W H Nuttall Synthetic Resins

TUESDAY, JANUARY 20

ROYAL INSTITUTION OF GREAT BRITAIN, at 5 15 —Dr J W T Walsh The Art of Illumination (1).

ROYAL SOCIETY OF MEDICINE at 5 30 —General Meeting

ROYAL PHOTOGRAPHIC SOCIETY OF GREAT BRITAIN at 7 —G H Dannatt The Island of Walcheren

LEICESTER LITERARY AND PHILOSOPHICAL SOCIETY (Botany and Biology Section) (jointly with University College Biological Society) (at University College Leicester), at 7 30 —Prof J H Priestley The Growth of a Tree

INSTITUTION OF ELECTRICAL ENGINEERS (East Midland Sub Centre) (at Ericsson Telephones Ltd , Beeston) —T Engblom The Totalisator

WEDNESDAY, JANUARY 21

SOCIETY OF GLASS TECHNOLOGY (at Newcastle-upon Tyne) at 2

ROYAL COLLEGE OF SURGEONS OF ENGLAND, at 5 —Prof J B Hume The Pathology of Diaphragmatic Hernia

INSTITUTION OF ENGINEERING INSPECTION (at Royal Society of Arts), at 5 30 —J R Cowie Metal clad Switchgear

ROYAL MICROSCOPICAL SOCIETY (at B M A House, Tavistock Square) (Annual General Meeting), at 5 30 —Prof R. R. Gates Adaptations in Cellular Structure (Presidential Address)

NEWCOMEN SOCIETY FOR THE STUDY OF THE HISTORY OF ENGINEERING AND TECHNOLOGY (at Caxton Hall), at 5 30 —T E Lones The South Staffordshire and North Worcestershire Mining District and its Relics of Mining Appliances

BRITISH WOOD PRESERVING ASSOCIATION (at 29 Lincoln s Inn Fields), at 6 30 —Col Sir G L Courthope and others Discussion on The Preservative Treatment of Estate Timber

INSTITUTION OF ELECTRICAL ENGINEERS (Tees side Sub-Centre) (at Cleveland Technical Institute, Middlesbrough), at 7 —D B Hoseason The Cooling of Electrical Machines.

INSTITUTION OF ELECTRICAL ENGINEERS (Sheffield Sub Centre) (at Royal Victoria Hotel, Sheffield), at 7 30.—J Scott MacKenzie The Generation of Electricity by Non Statutory Undertakings.

SOCIETY OF DYERS AND COLOURISTS (Midlands Section) (at Technical College, Derby), at 7 30 —A. J Hall Fine Structure of Artificial Silks in Relation to Dyeing

ROYAL METEOROLOGICAL SOCIETY (Annual General Meeting), at 7 40 — Presentation of the Buchan Prize to Dr C E P Brooks —R. G K Lempfert The Scientific Work of the Meteorological Office, Cardington (Presidential Address).

ROYAL SOCIETY OF ARTS, at 8 30 —M S Briggs Mosques and Minarets —an Introduction to Persian Architecture

ROYAL SOCIETY OF MEDICINE, at 9 15 —Dr A. Chaplin Great Figures in History and Misconceptions removed

SOCIETY OF CHEMICAL INDUSTRY (Glasgow Section) —Prof C H Desch Crystal Structure and Chemical Action

THURSDAY, JANUARY 22

ROYAL SOCIETY, at 4 30 —Sir Thomas Stanton The Development of a High Speed Wind Channel for Research in External Ballistics.—C Cook The Yield Point and Initial Stages of Plastic Strain in Mild Steel.—P M S Blackett and F C Champion The Scattering of Slow α Particles in Helium

ROYAL INSTITUTION OF GREAT BRITAIN, at 5 15 —Prof H Dingle The Nature and Scope of Physical Science (1).

INSTITUTION OF ELECTRICAL ENGINEERS, at 6 —E T Norris and F W Taylor High Voltage Testing Equipments —B L Goodlet, F S Edwards, and F R. Perry Dielectric Phenomena at High Voltages

ROYAL AERONAUTICAL SOCIETY (at Royal Society of Arts), at 6 30 — Squadron Leader W R D Acland Deck Flying

ROYAL PHOTOGRAPHIC SOCIETY OF GREAT BRITAIN, at 7 —Projection of Films

INSTITUTE OF RUBBER INDUSTRY (at "Manchester, Ltd , Manchester), at 7 30 —E H Wallace A Comparison of English and American Technique over the Last Decade

LEICESTER LITERARY AND PHILOSOPHICAL SOCIETY (Chemical Section) (at College of Technology Leicester), at 8 —Exhibition of Films—(a) Story of Beautiful Colours (b) The Manufacture of Nobel Glasgow High Explosives

INSTITUTE OF BREWING (Midland Counties Section) (at White Horse Hotel, Birmingham).—J Stewart Malting Barleys of 1930

COKE OVEN MANAGERS' ASSOCIATION (Northern Section) (at Three Tuns Hotel Durham) —S. Tweedy The Variations in the Composition of Crude Benzol under Different Carbonising Conditions

FRIDAY JANUARY 23

ROYAL COLLEGE OF SURGEONS OF ENGLAND, at 5 —Prof J W Tudor Thomas Successful Grafting of the Cornea in Rabbits

INSTITUTION OF MECHANICAL ENGINEERS, at 6 —H N Gresley High Pressure Locomotives

INSTITUTION OF ELECTRICAL ENGINEERS (London Students Section), at 6 15 —Short Papers on Various Aspects of Lighting

INSTITUTE OF FUEL (at Institution of Civil Engineers) at 6 30 —Dr K Rummel The Calculation of the Thermal Characteristics of Regenerators (Melchett Lecture)

SOCIETY OF CHEMICAL INDUSTRY (South Wales Section) (at Thomas's Café, Swansea) at 7 —Dr R Lessing Recent Improvements in Coal Cleaning

WEST OF SCOTLAND IRON AND STEEL INSTITUTE (at Royal Technical College Glasgow), at 7 15 —J K Dickie The Coking Industry and its Development in Relation to the Manufacture of Iron and Steel

JUNIOR INSTITUTION OF ENGINEERS (Informal Meeting) at 7 30 —E. W Thompson The Progress and Development of Steam Generators

ROYAL INSTITUTION OF GREAT BRITAIN, at 9 —Sir William Bragg The Scattering of Light

SOCIETY OF CHEMICAL INDUSTRY (Chemical Engineering Group) (at Mining and Industrial Equipments Ltd , Derby) —J C Farrant Modern Grinding

SATURDAY, JANUARY 24

ROYAL INSTITUTION OF GREAT BRITAIN at 3 —Dr E Cammaerts Flemish Art (1) The Van Eycks.

PUBLIC LECTURES

FRIDAY, JANUARY 16

UNIVERSITY COLLEGE, at 5 —G P Wells Comparative Physiology (Succeeding Lectures on Jan 23, 30, Feb 6, 13, 20, 27, Mar 6 13, and 20)

MONDAY, JANUARY 19

LONDON SCHOOL OF HYGIENE AND TROPICAL MEDICINE (Public Health Division), at 5 —Dr F C Minett Certain Diseases common to Man and Lower Animals

UNIVERSITY OF LEEDS, at 5.15 —Prof A V Hill The Osmotic Pressure of Tissue Fluids

TUESDAY, JANUARY 20

UNIVERSITY COLLEGE, at 3 30 —Dr P Hopkins The Need of Psychologists and the Menace from Charlatans.

UNIVERSITY COLLEGE HOSPITAL MEDICAL SCHOOL, at 5 15—Dr J A Murray Induction of Cancer by Tar and other Agents. (Succeeding Lecture on Jan 27)

WEDNESDAY, JANUARY 21

LONDON SCHOOL OF HYGIENE AND TROPICAL MEDICINE (Public Health Division), at 3 —Prof J W H Eyre Shell fish and the Public Health —At 5 —D S Rabagliati Certain Diseases common to Man and Lower Animals

KING S COLLEGE, LONDON, at 5 30 —Prof A P Newton The Great Age of Discovery (1) The Expansion of the Habitable World

LONDON SCHOOL OF ECONOMICS, at 6.—Dr G P Crowden Muscular Work and Fatigue (Succeeding Lectures on Jan 28 and Feb 4)

BELFAST MUSEUM AND ART GALLERY, at 8.—Prof Walmsley Sand Castles

THURSDAY, JANUARY 22.

UNIVERSITY OF LEEDS, at 8.—L. Ashton Persian Textile Art.

Standardisation in Industry

IT is now exactly thirty years ago since the British Engineering Standards Association (B E S A) was formed, namely, in 1901, when a small unpretentious committee was set up representing civil, mechanical, and electrical engineering institutions, together with the Iron and Steel Institute and the Institution of Naval Architects It may therefore justly claim to be among the pioneers of the movement towards more uniform and standard methods in industry, including simplification of forms and types, a movement which has now, in all the leading countries, reached vast dimensions and become a factor of supreme significance in industrial efficiency and progress Yet the Association worked for many years in obscurity and discouragement, and did not even receive its Royal Charter of incorporation until 1929, although it had for some time before this received a small grant from the Government This grant, never very substantial, was some time ago reduced to the pitiful allowance of 100 guineas per annum At length, however, the patient and indefatigable labours of the Association are receiving some measure of the recognition that they deserve, it has been promised a greatly increased grant from the British Government, and its work has also been commended by the recent Conference on Standardisation—in connexion with the Imperial Conference of 1930 the report of which has recently been published (Cmd 3716 London H M Stationery Office 3*d*)

This report takes note of two kinds of standardisation, distinguished as (*a*) fundamental standards and (*b*) industrial standardisation The former deals with standardisation of measurement units, and the latter with the rather wider field of industrial simplification and uniformity, and the adoption of standard specifications of material and method in all branches of industry where they can be usefully applied How wide this field is may be gathered from a glance through the rapidly growing list of the B E S A specifications, which now number several hundreds, and are constantly being added to and revised and brought into line with the most improved and up to date methods So much is this the case, indeed, that at its last general meeting the B E S A decided to eliminate the term 'engineering' from its title and all its publications, for it is now generally felt by the Association that 'engineering', despite its vast extent and almost infinite ramifications, is yet not sufficiently comprehensive to cover all the work of

the B E S A The question of a more suitable title is still under consideration, and its solution is not so simple as it looks

Several other important and interesting matters also came up at the last general meeting In the first place, the letter from the Board of Trade announcing the increased Government grant was read, stating that, in view of the recommendations in the final report of the Committee on Industry and Trade, it had been decided to make an annual grant of £3000 as from 1930–31 and for the next four years The Association's annual subscription list brings in about £13,000, and the Board of Trade grant will be increased in the year 1931–32 by £1 for every £3 that the Association may raise in subscriptions from industry in excess of £13,000 in the year ended March 1931, and similarly in the succeeding three years, subject to a maximum total of £5000 from the Government in any one year It is a condition of the grant that the Association will resume and energetically pursue the work of translating British standard specifications into foreign languages, organise local committees in oversea countries, and endeavour to strengthen its connexions with standardising bodies in other parts of the Empire with the view of the advancement of Imperial standardisation The position will be reviewed again by the Government at the end of the period of five years during which the annual grants will be made

The Association needs no exhortation to carry out these conditions, for they have indeed been the essence of its policy for many years, in particular, the work of translating and of co operating to the utmost possible extent, not only with other Empire bodies but also with foreign, has always been in the foreground and has been given the closest attention The chairman, at the last meeting, was in fact able to refer with justifiable pride to the excellence, for example, of the recent Spanish translations, which would greatly facilitate the spread of standardisation not only in Spain but also in the great and rapidly developing communities of South America

By way of exemplifying the tremendous growth and extent of the new fields to be covered, it is only necessary to refer to the comparatively new industries of aviation and wireless In both of these there is almost unlimited scope for standardisation, and already numerous specifications have been agreed upon and published Tentative feelers have been put out also towards the chemical industries and several conferences have been held Hitherto, the work of drafting agreed specifications as a basis for contracts and other purposes has been undertaken by individual industries, very often in collaboration with foreign and Imperial interests in the same industry, as, for example, in the glycerine standards and specifications, but the chairman of the B E S A is of opinion, and says that it has been generally agreed, that the greatest advantages to be obtained from industrial standardisation would be by the co-ordination of all efforts in a single national organisation This, on the face of it, appears a very desirable ideal to aim at, but if, beside national co ordination, one also considers Imperial and foreign co ordination in all fields of industry, then the whole idea becomes almost colossal

Great progress has already been made in the desired direction, but the meetings which have been held during the past year by the Central Committee at the Board of Trade have shown very clearly the difficulties of putting into operation on any extensive scale even a national scheme of simplification, without taking into account the further problems of international collaboration In the national sphere some progress has been made in the building industry, and a very interesting illustration of the Association's widened aims is the recently published specification for the sampling and analysis of small coal, which has been undertaken in co operation with the Fuel Research Board This is the first time that a British standard specification has been brought into ordinary everyday commercial relations with the coal industry, and the result cannot fail to be of national value

The electrical branch of the Association is probably among the most active, especially now that it includes under its ægis the rapidly developing wireless industry and is also growing strongly in other directions In this branch, too, the international aspect has to be very carefully studied During the past year, a largely attended meeting of the International Electrotechnical Commission was held in Scandinavia, when more than fifty British delegates were present, and every attempt is to be made to adopt the recommendations of this Commission in electrical work in Great Britain Similar work is being done in the wireless industry Other directions in which important and interesting work is being done relate to illumination and transport Efforts are being made to evolve a standard for artificial daylight, especially with the view of assisting in colour matching

Generally, the relations of the Association with

the standardising bodies in other countries and oversea dominions, already cordial, are being strengthened and developed, and the recommendations of the Imperial Conference in this matter have been anticipated

The report of the Conference on Standardisation, already referred to, deals, as we have seen, with the two kinds of standardisation, one of which, the industrial, has been briefly considered in connexion with the work of the B E S A The other kind, relating to fundamental standards, is really a constituent part of the wider field of industrial standardisation, for this latter necessarily implies uniform and fundamental standards of measurement

The Conference agreed that Imperial uniformity in these standards is highly desirable, and most of the oversea delegates expressed the view that British standards should be used whenever possible To this end it is necessary (*a*) to provide in each dominion and in India suitable reference standards for each such unit of measurement used in that country, and (*b*) to provide means for comparison with the corresponding standards at the Board of Trade or the National Physical Laboratory , also that at least one member of the Commonwealth should undertake research so that the fundamental standards can be referred ultimately to natural standards, such as the wave-length of light The requisite facilities and organisation for such work already exist or are contemplated in most of the oversea dominions, and it remains for closer co operation to be realised It may therefore be expected that in many parts of the Empire the standards of derived units, such as the volt, ohm, and the units of length in terms of the wave length of light, will soon be realised independently Nevertheless, periodical comparison with the standards in Great Britain should continue, and the report schedules a list of the principal units for which reference standards are likely to be required, with suggested procedure in regard to each

The report is a useful summary of the work done or proposed in reference to standardisation in various parts of the Empire, and while it does not add greatly to the knowledge of those closely engaged in this field or contain any very original suggestions for solving the many formidable difficulties to be encountered, it provides a definite basis for further work on agreed lines Moreover, it bestows an official blessing on what is being done and justifies a hope of wider and more intelligent recognition and support

Morphology of High Molecular Weights.

Der Aufbau der hochpolymeren organischen Naturstoffe auf Grund molekularmorphologischer Betrachtungen Von Kurt H Meyer und H Mark Pp viii + 264 (Leipzig Akademische Verlagsgesellschaft m b H , 1930) 18 gold marks

THE problem of fibre structure has been well to the fore during the last few years, especially in the minds of our German friends, and this really stimulating book is the outcome of their meditations on a subject the interest and importance of which are difficult to over estimate One might almost claim that the study of fibre structure and fibre properties, carried to its logical limit in the study of *molecular fibres*, is comprehensive enough to include most of the physico chemical phenomena of living matter , and because we are in the habit of clothing living matter with once living matter of a fibrous nature, it should be still more easy to substantiate the claim that fibre study is of fundamental importance to industry also At all events, it would seem that this truism has become palatable in Germany, for here we have a book of first rate ' academic ' interest emanating from such an address as ' Ludwigshafen a /Rhein, Hauptlaboratorium der I G Farbenindustrie "

It is scarcely possible to suppress a certain twinge of regret that we of Great Britain, so largely dependent on the success of our textile industries, should have played a comparatively inactive part in the actual structure analysis of natural fibres, in spite of the consolation that is to be gathered from the preface and introductory chapters of "Der Aufbau der hochpolymeren organischen Naturstoffe " The authors state plainly at the outset that their treatment of the subject is based primarily on the Bragg concept of atomic and molecular ' sizes ', and it is clear that the very considerable success that has attended the analysis of cellulose structures arises from the reasoned application of this principle to the Haworth-Freudenberg formula for cellulose The extension of the method to the cases of india-rubber, natural silk, and similar polymerised systems, followed naturally As a matter of fact, model building has long been a helpful pastime in the Bragg school of crystal analysis, even when the more systematic Continental mind tended to view it with a suspicion which subsequent events have proved to be scarcely deserved

The great merit of the volume under review lies

in the attempt to correlate a large amount of physical and chemical information with the results of X-ray analysis, a treatment which serves to show once more that structural crystallography is not simply a branch of chess, but a study of such varied applications and possibilities that it is no longer just to regard it even as a sort of second handmaiden of the sciences It is high time that it took its proper place in our university curricula, so that ideals and aims such as those set forth in the work under notice may attract the attention they deserve and yield their richest returns

When X ray analysis points to a small unit of structure and adds a rider to the effect that the periodicity is sound in only one direction, while physical chemistry insists on a high molecular weight, the inference is that we are dealing with crystals, or pseudo crystals, built up of those typical products of biological activity which the authors call "Hauptvalenzketten On this thesis they have developed an admirable account of the fascinating ascent which leads from the 'ideally perfect' crystal known as diamond, up through the half way house of the long chain paraffins and their derivatives, and on through the synthetic polyoxymethylenes of Staudinger to the complex carbohydrates and proteins, where finally the true crystalline state is lost in the realm of averages and distortions The whole story is pre eminently that of the evolution of the "Haupt valenzkette", even at the risk of offending chemists who might possibly maintain that there is more in protein chemistry than the various permutations and combinations of amino acid chains in simple peptide linkage There are those who are prepared to ascribe some part, at least, of the enormous variety in proteins to certain differences in the type of linkage—but it is good, very good, to emphasise the significance in protein structure of mixed crystallisation and its molecular counterpart, the formation of 'mixed molecules' "Weiter folgt daraus, dass die Bestimmung des Molekulargewichtes aus dem Gehalt des in kleinster Menge vorkommenden Spaltproduktes nicht ohne weiteres brauchbar ist, denn es brauchen nicht alle Moleküle eines Eiweisskorpers auch alle Spaltprodukte zu enthalten, da ja die Voraussetzung, dass alle Moleküle einander gleich sind, nicht mehr gegeben ist" This much, at least, seems clear even from the X-ray analytical data so far available in this field

There can be no hesitation about recommending "Der Aufbau der hochpolymeren organischen Naturstoffe" as a valuable contribution to the literature of both structure analysis and orthodox chemistry The research worker, whether academic or industrial, cannot fail to appreciate its helpful and stimulating qualities and find in it a useful source of reference in a wide range of ideas Above all, there is a very clear account of the X-ray analysis of cellulose and its derivatives, india rubber, natural silk, and certain other proteins, the whole being enriched by the interweaving of such supplementary and explanatory material as requires a table of 346 references

W T ASTBURY

The Great Barrier Reef

A Year on the Great Barrier Reef the Story of Corals and of the Greatest of their Creations By Dr C M Yonge Pp xx + 246 + 70 plates (London and New York G P Putnam's Sons, 1930) 21s net

THE Great Barrier Reef is one of "the wonders of the world", a breakwater built by living organisms extending along 1200 miles of the Queensland coast Its seaward edge varies from 10 to more than 100 miles from the shore, and the barrier is an almost continuous line in the northern half, giving place to a series of isolated reefs to the south On this barrier there are few islets, but the lagoon within is sparsely dotted with sand cays, on one of which, Low Island, Dr Yonge's expedition made its camp The continental coast behind varies, being in many parts high and cliffed, and having off lying islets of volcanic or granitic rock Many parts of it have been carefully surveyed in recent years by Prof Richards and his pupils A bore was also sunk to 600 feet on an islet situated about the middle of the Barrier, but only coral fragments and sand of the regular reef types were obtained Adherents of each theory of coral reef formation have in turn used the Barrier in support of their views, and this divergence of opinion was a clear indication of the need for further research upon the actual building organisms

In these circumstances the Great Barrier Reef Committee of Queensland decided to invite a biological expedition from the old country, and this was arranged by a large committee representing zoology, geology, botany and geography, the Empire Marketing Board, most scientific societies and the University of Cambridge co-operating With Dr Yonge, who undertook experimental work on the nutrition of corals, were F S Russell in charge of plankton, A P Orr (hydrography) Drs T A

Stephenson and S M Manton (coral ecology and life-history), F W Moorhouse (economic animals), S M Marshall (plant plankton), G Tandy (botanist), together with seven volunteer assistants and a party of three geographers With a few black boys and visitors, the camp had to provide for more than twenty persons, while half of the party required laboratory accommodation similar to that in our universities Low Island itself is less than 4 acres, but it is on the edge of a shoal of more than 400 acres, most of which is covered with mangroves or shingle exposed at low tide The seaward reef is largely covered with corals and the whole Barrier is in the East Indian belt, perhaps for marine biology the richest part of the world

Coral anemones are the chief reef builders by means of their elaborate skeletons of lime, which are excellently described and illustrated They paralyse their prey by throwing out stinging cells at passing animals and then engulf them Their whole surface is covered by vibratile hairs (cilia), the main function of which is shown to be the keeping of their surfaces clean They also assist by directing a current of water with its organisms into the coral mouths, out of which all excreta and the coral larvæ are passed by the same means The corals are carnivorous, "vegetable matter is useless to a coral" In the inner cell layer of the coral polyps are countless numbers of tiny round unicellular algæ, which appear to supply oxygen to the corals, while they obtain the normal food materials of plants from their host's excretion In correspondence with these methods of feeding, most corals seem to expand at night and to contract in the day The same system, perhaps, applies to *Heliopora*, *Millepora*, and many other animals allied to the true corals, but we have to await the publication of the author's experimental work The life-histories of corals were studied, the young being extruded from the mouth as planulæ, small masses of cells which float away in the currents These were found to be extruded during the summer at regular intervals of one month "over the period of full moon", but in autumn the intervals increased so that extrusion began to appear "about the period of the new moon" This "lunar periodicity" was better marked in *Chiton*, which, "collected the day before, spawned on the night of full moon" Observations were also made on the rate of growth of corals which were embedded in cement blocks Photographs show an increase in diameter of 40 to 80 per cent in six months

Many other reef inhabitants are described The giant clams are divided into two groups, one of which is seated on the surface of the reef, while the other works its way into the rock, so that the mantle edges look like undulating worms of brilliant hue moving over the reef below This edge was found to be covered with a brown scum of cells similar to the algæ of corals, which here are regarded as playing "an important part in the nutrition of the animal" While some of these "giant cockles" reach a length of 4½ ft—a pair are used as holy water stoops in St Sulpice in Paris and weigh a quarter of a ton—the common burrowing species are quite small, sixteen having been found in an area of 18 inches square Of still more importance is the date stone (Lithophaga), a bivalve which bores by "special glands pouring out an acid" Bêche de-mer, "animated sausages" of large size, continuously shovel sand into their mouths and by triturating it assist in reef destruction They are fished largely by the aborigines of the Torres Strait region, being split open and dried, to be exported afterwards to China for soup The pearl shell industry was already well known, but the *Trochus*, a large coiled mollusc, has only been developed as a result of the War, the total export being probably about 1000 tons, valued at £100,000 The animal grows at the rate of about an inch a year for four years, reaching a maximum of 6 inches, but slowing down after 4 inches It breeds during the winter months, and the adults have quite remarkable powers of hiding away under rocks The sponge industry seems as yet little developed

The description of the work of the expedition on the surface fauna and flora is an excellent account of this line of research, the means by which it is pursued, and the objects sought It is noticeable that there is little fluctuation in the plant plankton during the year, and that the numbers on the average are less than in temperate seas A good point is made in regarding the coral algæ as "imprisoned phytoplankton" intercepting "the nutrient salts which the coral would otherwise excrete into the sea and so increase its fertility" The vertical movements of the plankton were especially studied, the depth of its concentration being all important to the animals which feed upon it There are interesting accounts of the bottom fauna and of visits to Thursday Island, the Torres Straits barrier, and the Capricorn group, but the full record of these must be sought in the scientific publications of the expedition The story is of natural history, and our author, who has a fine journalistic sense,

loves his beasts and applies the biological methods of 1928 to his study of them His book must be read by every student of marine biology, and will be found entertaining by that far wider circle which is interested in the wonders of the world

Archæology from the Air

Ordnance Survey Professional Papers New Series, No 12 *Air Photography for Archaeologists* By O G S Crawford Published by Order of the Director General, Ordnance Survey, under the Authority of the Ministry of Agriculture and Fisheries Pp 44+19 plates (London H M S O , Southampton Ordnance Survey Office, 1929) 4*s* 6*d* net

AIR photography has ceased to be a novelty or a toy, when the Ordnance Survey Office issues a ' professional paper ' for the instruction of archæologists in the reading of air photographs, with hints for airmen also, on the making of such photographs of ancient sites For ' shadow sites ', recorded with the very oblique light of dawn or evening, need different treatment, and yield different results, from bare soil and rocks, best avoided at any time, and from ' crop-sites ' where the growth varies as ancient walls or ditches present either more or less than normal soil or moisture How striking these variations may be, appears from these admirable photographs, despite the elimination of colour-contrast In Nature, they may often be detected by pedestrians , and, as is noted on p 4, this method of archæological survey goes back some way—even further than is stated, for in the reference to Northfield Farm 1904 should be 1894, and the significance of weeds among the corn was suggested by even earlier experience among the tomb-robbing peasantry of Cyprus There the contrast was enhanced by the effects of parching, such as is described on p 5 and it may be noted that Mr Crawford's hopes of " another dry year " were realised in the summer of 1929 Soon, it is hinted, we shall find the normal rotation of crops interrupted by archæological insistence on horse-beans, which have long enough roots to register deep seated antiquity

One of the more remarkable revelations of this air photography is to display the very wide extent of earlier farming Very few tracts have survived altogether untouched , and the question arises, What is the significance of all this, from the points of view of economic history and climatology? Another, not specifically discussed in this memoir, is the marked difference in texture, as seen from the air, of different kinds of grassland, according to the subsoil and geological foundation

What a training in observation, and the significance of things seen, is all this archæological work for the pilots of the Royal Air Force, who have actually taken the photographs! For it is a very different thing to record known objects, however ingeniously devised to be puzzling, and to engage in what is at the same time real research, in the sense that not even the archæological officer knows beforehand what there will be to see , though evidently he has usually a shrewd notion what is worth exploring and what is not

This memoir is an indispensable supplement to the author's " Wessex from the Air ", and the four plates borrowed from that book were worth reprinting for the sake of their present letterpress and the light thrown on them by their present company

The Position of Women in India

The Key of Progress a Survey of the Status and Conditions of Women in India By several Contributors Edited by A R Caton Pp x + 250 (London Oxford University Press, 1930) 7*s* 6*d* net

MISS CATON and her collaborators have produced a book which is indispensable to the student of Indian problems—social, religious, educational, sanitary, industrial, and political The backward condition of the women in India is one of the root-causes of the backwardness of India as a whole, and the title of the book is taken from a striking sentence in the Simon Report—" the women's movement in India holds the key of progress, and the results it may achieve are incalculably great "

The eight chapters on education, health and sanitation, public life, home and marriage, rural life, industry, and social evils are documented at every point , and the references, which, apart from a few slips of trifling importance, are accurate, give a mass of important facts, skilfully and conveniently arranged

The section on education is largely based on the Report of the Education Committee of the Simon Commission It points out that in British India the percentage of male literates in 1921 (at the last census) was 13 0, of female literates 1 8, and that up to 1921 the discrepancy in literacy between men and women was increasing The discrepancy between the number of boys and girls under instruc-

tion is also increasing. Between 1922 and 1927 the increase in the number of boys under instruction was 2,400,000, the corresponding increase in the number of girls was only 400,000

The obstacles to women's education and all that it means are conservatism in social customs, purdah, and early marriage, and these, with want of education, are the great enemies of women's health in India, and contribute largely to infant mortality Dr A Lankester reported in 1920 that in many cities in India more than twice as many women suffered from phthisis as men Dr K Vaughan, writing in 1928, attributes most of the trouble in child-birth in India to the lack of sunlight due to purdah, with, as its result, osteomalacia and gross pelvic deformity (and it may be added, anæmia) It must, however, be remembered that in large tracts of India, for example, Bombay and Madras, purdah does not prevail (though, except in highly educated circles, the sexes do not mix as in the west) All over India, in spite of recent efforts, the number of skilled doctors and of skilled midwives is small, and the ordinary midwife is desperately inefficient The recent Report of the Age of Consent Committee (1929), of which only one member was European, gives a painful picture of the effects on health of marriage below the age of sixteen It is to be hoped that the new Sarda Marriage Act (which could probably not have been passed but for the Age of Consent Report) may stop the evil—when it is enforced

In turning over the pages of Miss Caton's book it is impossible not to be impressed by the immensity of the work still to be done On the other hand, there has been a real awakening in India, as every recent report shows Discounting a good deal of lip-service (especially on the educational side), we must recognise the existence of a large number of agencies, educational, medical, and social, for the improvement of the conditions of girls and women Indian women themselves, coming from educated and comfortable homes, are now pleading in public the cause of their less fortunate sisters, and some of them have recently occupied conspicuous positions in the world of politics and education The late Begum of Bhopal was Chancellor of the University of Aligarh, and an able Chancellor, Mrs Muthulakshmi Reddi was an extremely active Deputy-President of the Madras Legislative Council But it is in the villages that a change in the position of women is perhaps the most important Mr F L Brayne, who has done so much in the Gurgaon district of the Punjab, writes: "If I might pick out the heart and centre of the uplift campaign, I should say that it was the elevation of the women"

One must not exaggerate Inside many Indian homes, the influence of the woman, and especially the grandmother, has been supreme But the transformation of India, necessary to make her come into line with other countries, will only be possible when the brains of the women are utilised to a far greater extent than at present There is no sign that they are inferior to those of women in the west

Our Bookshelf

A Cultural History of the Modern Age the Crisis of the European Soul from the Black Death to the World War By Egon Friedell Translated from the German by Charles Francis Atkinson Vol 1 *Introduction* Book 1 *Renaissance and Reformation, from the Black Death to the Thirty Years' War* Pp ix + 353 + vii (London Alfred A Knopf, 1930) 21s

THIS is an extraordinarily stimulating and attractive book It inclines a reviewer to write far more than his editor could possibly include, for every page either gives provocative pictures of leading figures in the past or else raises profound and eternal questions for discussion The author sets out to give an "incomplete" but artistic presentation of the modern European world to pick out, that is, those features in the modern world which he finds of most significance—especially of spiritual significance He writes well and with enthusiasm Among recent historical works noticed in these columns, the book most like this is Dr Wingfield-Stratford's "History of British Civilisation" What he does for England, Dr Friedell has begun to do in this volume for Europe

One striking point in which the present author differs in his general outlook from Dr Wingfield-Stratford raises one of those great questions which we should like to discuss at length Dr Friedell declares that his is not to be an economic history, and that "economic life, far from being an adequate expression of any culture, does not, strictly speaking, belong to culture at all, only contributing one of its preliminary conditions and not the most vital" So far we might agree with him But when he goes on to treat science as the lowest part of the thinking side of man, inferior to philosophy and far inferior to religion, we feel less confidence in his powers of analysis Science cannot thus be identified with technology and marked off from the sphere of creative thought which embraces art, philosophy, and religion If art is creative in an individual and eternal form which is denied to any particular scientific construction, yet the mental process has common creative elements in both cases, and to treat philosophy and religion as independent of science would, if it were possible, be a still more serious mutilation of the reality of thought

F S M

Handbuch der Experimentalphysik Herausgegeben von W Wien und F Harms Unter Mitarbeit von H Lenz Band 25, Teil 3 *Angewandte Geophysik* Unter der Redaktion von G Angenheister Pp xii + 556 (Leipzig Akademische Verlagsgesellschaft m b H, 1930) 54 gold marks

THIS work opens with a short account (48 pages), by H Reich, of the geological foundations on which applied geophysics must build, the remainder of the book consists of small treatises on the various methods, each by a specialist in the method Gravimetric methods are discussed by K Jung (162 pages), the next section, on seismic methods, is divided into two parts, one (of 40 pages), by O Meisser, on 'air seismology', and the other (of 55 pages) on earth seismology, the former, though interesting in itself, seems out of place in the present volume, as it bears on the constitution of the upper atmosphere, and not on that of the earth's interior, to which applied geophysics (as now understood) refers Magnetic methods of prospecting are discussed in 100 pages by H Haalck, and electrical methods by J N Hummel and W Heine, the former dealing with the theory (67 pages) and the latter with the practice (56 pages) J N Hummel also contributes the final section (28 pages) on radioactive methods

The price of the book, 54 gold marks, seems excessive, but will doubtless not deter commercial users, who are those chiefly concerned with the subject, from purchasing a copy Even they, however, may feel that the multiplication of books covering much the same ground can be overdone, especially when at so expensive a rate Some of the joint authors of this volume have recently published fuller accounts, in separate books issued by another publisher, of the sections which they here deal with, the shorter accounts in the present work have the advantage, however, of including mention of the most recent work, with references

Egyptian Civilization its Sumerian Origin and Real Chronology, and Sumerian Origin of Egyptian Hieroglyphs By Dr L A Waddell Pp xx + 223 + 21 plates (London Luzac and Co, 1930) 12*s* 6*d* net

IN this volume, the seventh of the series that Col Waddell has devoted to the exposition of his views on the origin and relations of the great civilisations of antiquity, the author aims at demonstrating the historical character of Menes as an Aryan, a descendant of the first Sumerian or Aryan king who founded civilisation He maintains that Menes was at one and the same time the Sumerian emperor in Mesopotamia and the first dynastic king of Egypt, a crown-colony of his world empire

In a previous volume it has been held that Harappa and Mohenjo Daro are the relics of a Sumerian colony in India Arguing from identifications in the king lists of India, Mesopotamia, and Egypt, it is now maintained that Menes was the son of Sargon, the ruler of an empire extending from India to Britain Egyptian civilisation is made to date from the conquest of the country by the pre-dynastic Pharaohs, now shown to have been Sumerian emperors, the father and grandfather of Sargon, the date of the conquest being about 2780 B C Menes, the crown-prince and governor of the Indus valley, erected Egypt into an independent kingdom, civilised Crete as Minos or Min, and extended his power to the Pillars of Hercules and Britain Col Waddell regards any discrepancy between his theories and those of a more orthodox chronology as due to the weakness of archæological dating, but until he convinces scholars of the accuracy of his identifications—a difficult task, we fear—his own chronology hangs in the air

The Art of Study By Prof T H Pear Pp. vii + 117 (London Kegan Paul and Co, Ltd, 1930) 3*s* 6*d* net

THIS book is the outcome of some broadcast talks to school children on how to concentrate The author has expanded and developed these talks so that they apply not only to school children, but also to children of maturer years who may find they want to study something and yet feel they do not know how to do so

Perhaps nobody but Prof Pear can put abstract psychological problems in such a winning way, the chief difficulty is that the knowledge behind his exposition is so artistically disguised that readers may erroneously believe that the problems involved are really very simple He discusses what we mean by learning, the differences in people with regard to mental make-up so that a method of study useful to one may be a stumbling-block to another, how to form habits of study, how to memorise Interspersed between the facts is much good advice, tendered by one experienced in the difficulties of learners

This book can be recommended as really being what it is called, the art of study, the science of study forms the background

Jorullo the History of the Volcano of Jorullo and the Reclamation of the Devastated District by Animals and Plants By Dr Hans Gadow Pp xviii + 100 + 2 plates (Cambridge At the University Press, 1930) 7*s* 6*d* net

JORULLO stands in an amphitheatre amongst the foothills of the great southern slope of the Mexican plateau It was subjected to a series of eruptions between 1759 and 1775, about five square miles of land being buried and probably at least ten times as much completely devastated The late Dr Gadow, who meditated a larger work on the distribution of animals in Central America, spent a month there and tells the story of the repeopling of the area by plants and animals These penetrated the devastated area at an average rate of a mile in forty years This is slow as compared with Krakatoa, to reach which most organisms must have used sea transport, but this is explained by the situation of Jorullo being in a comparatively dry area We would not care to draw deductions after a month's collecting, but Dr Gadow was unique in his knowledge of the ways of reptiles and amphibians, upon which mainly he bases his views

Mercury Band System in the Neighbourhood of the Resonance Line

A BAND in the mercury spectrum referred to as 2540 has been the subject of much discussion, owing to its proximity and apparent relationship to the resonance line 2536 52, and to the fact that it is seen in absorption by unexcited mercury vapour of suitable density I have long suspected that this is only one feature of a complicated band system in this neighbourhood The investigation is much embarrassed by the glare of the resonance line, which makes it difficult to photograph delicate details in the immediate vicinity

Recently examining some old spectrograms of a water-cooled mercury arc, I have been able to measure two similar and additional bands between this one and the resonance line The wave lengths are 2540 37, 2538 44, 2537 32 These are shaded *from* the red

In addition, two bands have been measured on the other side of the resonance line at 2535 82 and 2535 35 These are shaded *to* the red

There are faint suggestions of much more, which could probably be made definite if the source were carefully adapted to the purpose Unfortunately, the large spectrograph used was destroyed by fire, which hinders any immediate progress

Methods of Investigating the Intensities of γ-Rays

THERE are two important methods of investigating the intensities of γ-rays, that of Skobeltzyn (*Zeit f Phys*, **43**, 354, 1927 **58**, 595, 1929) and that of Ellis and Aston (*Proc Roy Soc*, A, **129**, 189, 1930) We wish to point out that the results of the measurement of the intensities of the γ rays of radium B and radium C by these two methods are in as good agreement as can be expected

Skobeltzyn's method, which depends on the Compton effect, determines the intensity distribution throughout the spectrum, in the sense that it gives the quantity I_ν when $I_\nu \Delta\nu$ is the aggregate intensity of the γ rays the frequencies of which lie in the interval ν to $\nu + \Delta\nu$ The quantity $\Delta\nu$, in this connexion, is not a differential, but is to be understood as an interval determined by the conditions of the experiment In certain parts of the spectrum where there are two or more strong γ-rays close together, it is not possible to separate their effects, and, as can be seen from col 3 of the following table, the Compton effect method gives the summated intensity (cf Skobeltzyn, loc cit, **58**, 609, Table 2, col 4)

The method used by Ellis and Aston depends on the photoelectric effect, and while there are certain definite disadvantages in the method, it does possess the important advantage of giving the intensities of the individual γ-rays These are shown in col 2 of the table corrected for filtering through 3 5 mm of lead to correspond with the conditions of Skobeltzyn's experiment The ratios of the intensities obtained by the two methods are given in col 4, from which it will be seen that there is on the whole good agreement

To see what can be deduced from this agreement it is necessary to refer briefly to the main features of the measurements Skobeltzyn's method depends on observing by the Wilson cloud method the relative number of electrons ejected within a certain angular range by the Compton effect of the different γ rays. It is generally accepted that the data about absorption

INTENSITIES OF THE γ RAYS OF RADIUM B AND C

$h\nu$ of the γ-rays (volts × 10^{-5})	Intensities by photoelectric method after 3 5 mm lead (I_p)		Intensities by Compton effect method (I_c)	$\frac{I_c}{I_p}$
2 43	0 011			
2 97	0 056	0 22	1	4 5
3 54	0 152			
6 12	0 415	0 46	1 8	3 9
7 73	0 046			
9 41	0 050			
11 30	0 160	0 26	1 19	4 5
12 48	0 050			
17 78	0 22		0 81	3 7
22 19	0 064		0 27	4 2

coefficients needed to deduce the relation intensities of the γ rays is sufficiently well known for purposes such as the present, and that there is no fundamental uncertainty in the method

Ellis and Aston's method, which depends on the photoelectric effect, determines essentially the relative values of the quantities $I_1\tau_1$, $I_2\tau_2$, etc, when I_1, I_2, etc, are the intensities of the γ rays and τ_1 and τ_2, etc, corresponding photoelectric absorption coefficients There is at present no direct experimental evidence about the variation of τ at these high frequencies, and to evaluate the results it was necessary to extrapolate from the X ray region by an empirical formula

The general agreement between the results of the two methods suggests that this extrapolation is approximately correct, and that we have therefore reasonable grounds for accepting the values of the individual intensities of such γ rays as were measured by the photoelectric method

In view of the important part played by the intensities of the γ rays in certain speculations about the structure of radioactive nuclei, we feel it is of interest to point out how these two methods, when combined, yield information which is far more definite than that supplied by either alone The certainty of the Compton effect method supplies just that deficiency in the photoelectric effect method, whilst the latter has the power of dealing with individual γ rays, the lack of which is the chief disadvantage of the Compton effect method A further point which brings out the complementary nature of the two methods is that the photoelectric method is best suited to lower frequency γ rays, whilst the Compton effect method deals, if anything, rather more easily with the higher frequency γ rays

Uniform Propagation of Flame

MASON and Wheeler,[1] following the initial observation of Mallard and Le Chatelier, considered that when a gaseous explosive mixture is suitably ignited at the open end of a horizontal glass tube, the other end of which is closed, flame travels at a uniform speed for some distance The results of their experiments have been extended further by Wheeler and

his collaborators to the formulation of a speed law,[2] which has since been criticised by Bone, Fraser, and Winter, and interesting experimental evidence brought to disprove the so called speed law[3] At about this time one of us (H K S) was engaged in the determination of ignition temperatures,[4] and came to recognise a certain approximate relation (1 2) between the ignition temperatures and flame temperatures of the mixtures generally studied for the uniform propagation law

From a mathematical analysis (a full account of which is being published elsewhere) we find that a regime of initial uniform flame propagation is *possible*, assuming that pressure plays no part during the short interval of this propagation Our analysis shows that uniform propagation is given by an equality (not by a certain quantity lying between two limits), which of necessity must be delicately balanced It is thus possible that in some mixtures uniform propagation may not exist

The velocity equation developed by us is more rigid than that of Mallard and Le Chatelier and takes note of the distribution of temperature in every section of the gaseous medium comprising the travelling flame For, whilst Mallard and Le Chatelier's formula implies that the gas immediately in front of the flame is at the constant room temperature, and that at the back is merely at the ignition temperature we incline to regard the travelling flame as a region having temperature gradients corresponding with the combustion temperature T, at the rear, and the ignition temperature, θ, at the front, in advance of this there is a

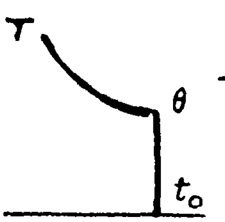

FIG 1
(Mallard and Le Chatelier)

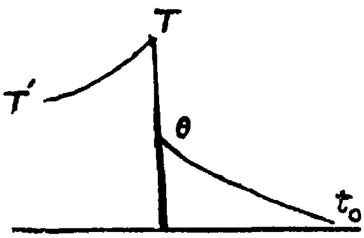

FIG 2
(Sen and Sen)

progressive fall of temperature to that of the cold gas t_0, due to the cumulative effect of the heat generated in the reaction (Fig 1 and Fig 2)

On examining our velocity equation we find that the condition for uniform propagation is $\theta = \frac{aQ}{\rho C}$ where

θ = the ignition temperature,
ρ = density of the inflammable mixture, and
C = specific heat,
aQ = the fraction of the total heat of combustion utilised for conduction

In applying this relationship it must be borne in mind that the flame, the seat of chemical reaction, which in our analysis has been replaced by a mathematical heat source actually possesses a finite width in which the temperature gradient is represented, say, by some curve, ABC in Fig 3

$PCAF$ represents the flame and $FA = \theta$ the ignition temperature In this distribution, account is taken of heat losses

$\frac{aQ}{\rho C}$ then represents the average temperature in the flame, the average being taken with regard to the width AD Moreover, since aQ corresponds to the heat available after combustion, the average temperature here is to be measured above the level of the ignition temperature AD, and is, therefore, given by the area $ABCDA$ divided by the width AD Let BM represent this average temperature given by $\frac{aQ}{\rho C}$ Hence the condition for uniform propagation is that θ, the ignition temperature, should be equal to BM, or, in other words, the average flame temperature should be double the ignition temperature of the combustible mixture The modification of the value of aQ may slightly disturb the condition As stated already, since the distribution of temperature in the flame is intimately connected with the velocity of chemical reaction, the latter may be supposed to be contained in the above condition

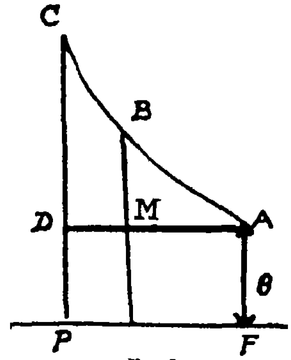

FIG 3

We are in a position to test in a few cases the validity of this relation by comparing the ignition temperature and the flame temperature of uniformly propagating mixtures

	Approximately Instantaneous Ignition Temperatures	Approximate Flame Temperature

Alternation in Properties of Long Chain Carbon Compounds

ONE of the most interesting features of long chain compounds in the solid state is the well known alternation in properties depending upon whether the chain contains an even or an odd number of carbon atoms The X ray work of Muller on single crystals and of Piper, and Muller and Shearer on the long crystal spacings has shown that long chain compounds crystallise in long zigzag chains lying perpendicular or tilted with regard to the planes formed by the terminal groups It follows at once that there will be a difference between chains containing an odd and an even number of carbon atoms, the terminal groups being respectively in the *cis* and *trans* positions It has been suggested by Pauly[1] and Nekrassow[2] that this is the cause of alternation, and Müller,[3] apparently unaware of this, came independently to the same conclusions

The difficulty with regard to this theory is that it implies alternation in all long chain compounds independent of the tilt of the chain (see Fig 1), whereas, actually, the paraffins, methyl ketones, alcohols, and ethyl esters of mono- and di-basic acids do not alternate It is now suggested by me that the essential

feature of an alternating series is that the zigzag chain is *tilted* with respect to the terminal planes

X-ray and thermochemical[4] work indicates that alternation is due to some difference in the terminal groups, it will be seen from the figure that there is no essential difference in the terminal planes, between odd and even, when the zigzag chain is vertical In tilted chains, however, a difference is at once apparent, alternate terminal planes of odd chains being less closely packed This is readily seen if the distances between penultimate carbon atoms in two chains are considered (a and b in Fig 1), over these different distances the same groups are responsible for holding the molecules together The stability of odd chains will therefore be smaller than that of even, and they will melt at the lower temperatures *

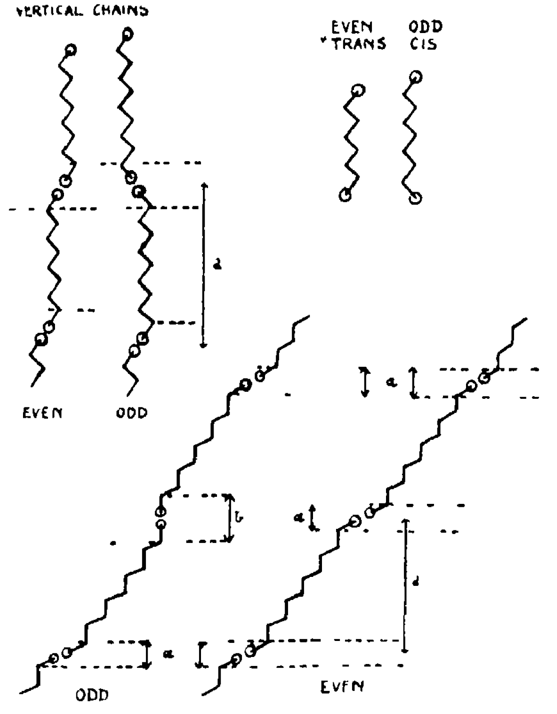

FIG 1—In the above diagrammatic sketch, the discontinuous lines are parallel to terminal planes Circles represent terminal groups d=long crystal spacing ($2d$ in the case of double molecules)

X ray evidence is in agreement with the above suggestion thus, non alternating series possess vertical chains (hydrocarbons, methyl ketones, alcohols), whereas alternating series possess tilted chains (mono and di basic acids, iodides, and nitrils) The following experimental facts are also clear from the figures (1) The long spacings of odd alternating compounds are always slightly greater, in proportion, than the even, whereas in non alternating series odd and even spacings increase linearly (2) The molecular volumes of solid odd fatty acids are greater than those of the even[5] (3) The even alternating series are more tilted than the odd, as was shown in the case of di basic acids[6]

The only apparent exceptions to the above rule are the ethyl esters of mono- and di basic acids, which normally possess tilted chains I now find that ethyl esters of fatty acids possess vertical chains just below the melting points, and although I have not examined esters of di basic acids, it is noteworthy that Normand, Ross, and Henderson[7] observed a second longer spacing for the ester of undecane dicarboxylic acid, which melts just a little above room temperature It seems probable that this longer form would appear generally, for the series, at temperatures not too far removed from the melting points

A detailed account of an investigation of the long spacings of ethyl and methyl esters, showing the alternate forms in which they both exist, together with a fuller discussion of the above, is in preparation It may be mentioned here that methyl esters differ fundamentally from ethyl, behaving in a weaker degree like the acids and crystallising in double molecules with the polar groups together This offers a satisfactory explanation of their anomalous high melting points, since ethyl esters crystallise in layers of single molecules

My best thanks are due to Mr S H Piper for his encouraging interest in the work

Optical Investigations on the Passivity of Iron and Steel

SOME results concerning the passivity of metals were described by me recently in NATURE,[1] and afterwards published *in extenso*[2] It may now be of interest to give some new data obtained by means of optical methods These experiments were all carried out by employing mirrors of iron and steel—both ordinary steel and stainless steel—electrolytically treated simultaneously in baths of alkaline, neutral, or acid sodium sulphate solutions Different current densities were used

It is well known that Drude[3] has developed equations which are valid for reflection in air, and by means of these it is possible to compute approximately the mean refractive index and the mean thickness of a surface film from the change in polarisation of the reflected light These equations have now been generalised so as to apply to any medium, and they consequently hold good also for films formed in aqueous solutions

In preparing the metal mirrors, special precautions should be taken to exclude the possibility of any increase in the thickness of the surface film, and I have always attached great importance to this point The constants found by the old methods of preparation are therefore not likely to agree so thoroughly with the true values for the compact metal—free from any 'air-formed' films—as do the optical constants obtained by the method employed in this investigation

According to Bannister and Evans,[4] the process of activation brings about destruction of the 'air formed' film, and thus a definite 'standard state' of the mirror could be obtained after a few minutes On the other hand, destruction of the mirror itself also occurred in some cases

It is remarkable that during the very first time of making the metals passive, all mirrors examined showed a change in the reflected light, which corresponded to the formation of a surface film with a mean refractive index of about 3·0 and a mean thickness of about 30 A The mean refractive index computed in this way agrees with

that of ferric oxide, and from this fact it is evident that the film is actually an oxide film, as demanded by the theory of Faraday Since the optical properties of the mirrors are constant during the process of continuous anodic treatment, independently of the current densities employed, it is further evident that the films should be impenetrable to the constituents of the solution, for example, to atoms or molecules of oxygen The metals are, therefore, made passive in the real sense of the word

As a general rule, reactivation did not completely remove the oxide skin, the destruction of the film on the ferrite grains, however, being more pronounced than that on the cementite grains Thus, by alternating cathodic and anodic treatment (the current was reversed three times in the course of three hours), the oxide film on the cementite particles was microscopically visible as dark brown spots, whereas on the ferrite particles faint yellow interference colours could be detected only by employing slanting incidence According to Evans,[5] the rate of destruction of the films decreases when the solutions are made alkaline, and hence the average thickness of the film is greater in these solutions than in neutral or acid baths

The experimental part of this investigation was carried out in the Metallografiska Institutet, Stockholm, and I wish to thank the Director of the Institute, Prof C Benedicks, for his help and kindness during this time A complete record of all data obtained are to be published in *Det Kgl Norske Videnskabers Selskaps Skrifter*, 1931 (*Transactions of the Royal Society of Science*, Nidaros, Norway)

Mechanism of Bengal Tornadoes in the Nor'wester Season

THE first requisite of tornado formation is a violent updraught of moist air In a paper on the nor'-westers in Bengal, which will be published shortly, it is being shown from a large number of weather charts that the nor'wester squalls during the period February to June are due to the katabatic flow of air wedges advancing along the valleys and undercutting moist southerly winds over the plains of Bengal In the afternoon when the moist air has attained a certain specified state, conditions become favourable for the formation of squalls near the 'noses' of the valley air-wedges The strength of the squalls increases with the depth of the valley and of the Bay air, and the temperature differences between the two air masses The accompanying diagram (Fig 1) is based on the 13 h I S T chart of April 27, 1930, when a passenger steamer named *Condor* was caught in a violent squall, believed to have been of tornadic violence, and sank at 17 h near Nagarbari

A detailed analysis of daily weather charts shows that the Bay current becomes divergent in the presence of a valley air wedge or barrier In the diagram the divergent moist air stream lines due to wedge-barrier *A*, advancing from the Brahmaputra valley, are the systems *a* and *b*, whilst those due to *B*, advancing from the Cachar valley, are *c* and *d* Of these, the systems *b* and *c* converge along the broken line *PQ*,

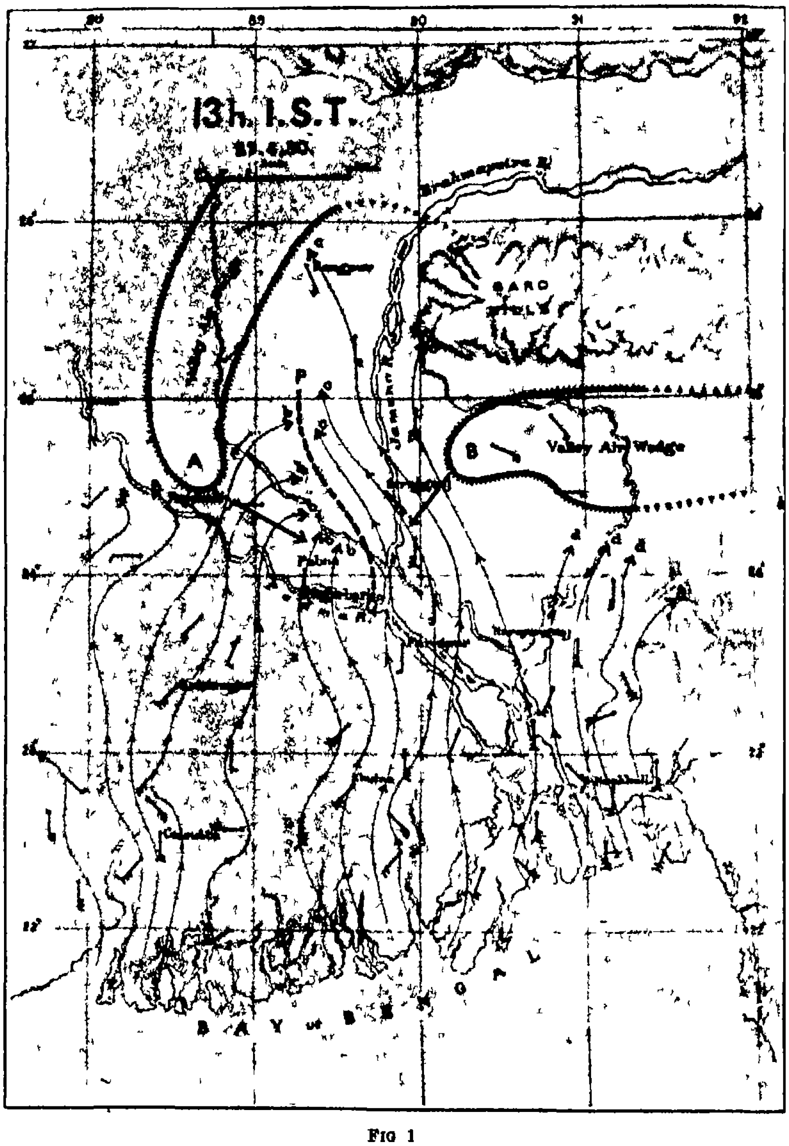

FIG 1

initiating an anti clockwise circulation between the two wedge barriers and consequently an updraught which is probably sufficient for ordinary thunderstorms The directions of motion of the 'noses' of *A* and *B*, indicated by the long thick arrows from the tips of the wedges, were such that the two 'noses' apparently collided with each other (*A* travelling approximately three times as fast as *B*) at Nagarbari, situated approximately at the junction of the two rivers, the Jumna and Padma The upward convection was, therefore,

much accentuated, due to the motion as well as the lateral displacement, slipping, or spreading of the wedge barriers

On the day of the *Condor* disaster the temperature contrast between the valley and the Bay air masses at the surface at 8 h was of the order of 8° or 9° C and their depth between 1 km and 2 km At and above 2 km level there was a westerly or north westerly circulation, wind speed increasing with height, which often carries with it super adiabatic lapse rates favourable to accelerated updraughts (*vide* Roy and Chatterji, NATURE, Sept 28, 1929, p 481) Inversions in the lower layers of the atmosphere over Bengal usually retard updraught of moist air until noon, but this factor often disappears in the afternoon

The above facts suggest that nor'wester thunderstorms can occasionally develop into tornadoes if additional favourable conditions can combine suitably

It appears from preliminary studies that the mechanism of the Bay of Bengal storms is similar to that of the tornado described above The subject is under investigation

The Latent Photographic Image

IN a recent letter to NATURE (Nov 15, 1930) A P H Trivelli replies to our criticism (*Proc. Roy Soc* A **127**, 613, 1930) of his "elementary voltaic cell" theory of latent image formation, originally put forward by him in 1927 (*J Franklin Inst*, vol 204, 649), and concludes that our criticism is not justified It seems from his letter that he has not realised the significance of our experimental results as they affect his theory We agree with him, of course, that the larger the silver nucleus originally present in the grain, the less is the amount of silver which must be added during the exposure in order that a development centre may be produced, and hence the greater the sensitivity of the grain But quite independently of the absolute mass of silver which (according to Trivelli's theory) must be deposited *electrolytically* during the exposure, his theory demands that the electrolytic current in the light shall be enormously great *relative to its value in the dark* We say this is extremely improbable, mainly because our experiments show that illumination causes little, if any, increase in the electrolytic conductivity of silver bromide

Our second criticism of Trivelli's theory is based on the fact that the electrolytic current in silver bromide falls exponentially with decreasing temperature, being 10^8 times less at the temperature of boiling liquid oxygen than at room temperatures On the other hand, photographic sensitivity at the former temperature is still a large fraction of its value at room temperature Trivelli says, "This objection again ignores the effect of the size of the pre existing speck Only if sensitivity specks were totally absent would the temperature coefficient of photographic sensitivity be comparable with that of electrolytic photoconductance" We cannot agree with this Since the mass of silver deposited in a given time by an electrolytic current depends on the magnitude of the current, a large decrease in current (by lowering the temperature) must necessarily produce a corresponding decrease in the *rate* at which silver is deposited This is a fact which is quite independent of the number of silver atoms which must be added to the original silver nucleus to make a development centre, and which is, therefore, unaffected by the size of the sensitising nucleus Therefore, on Trivelli's theory, the temperature coefficient of photographic sensitivity should, to some extent, be comparable with that of electrolytic conductance

On both these grounds it still seems to us that Trivelli's theory is quite incompatible with our experimental results

Structure of Hydrogen Sulphide and Hydrogen Selenide

IN NATURE of Dec 13, p 916, Prof L Vegard communicates the results of the investigation of crystalline structure of hydrogen sulphide and selenide, which were made by him in the Physical Institute of Oslo and finished in July last, while his letter is dated Nov 6

I may be permitted to recall that I have already published two papers on the structure of these substances These papers were presented to the R Accademia dei Lincei in Rome at the meetings of Mar 2 and April 6, 1930, and published in Fasc 7 and 8 of vol 11, 1st sem, pp 679 684, 749 754 Abstracts appeared in NATURE of Sept 6, p 387, and Sept 27, p 495

The data generally agree with those given by Vegard, as for both substances we found a cubic lattice, with face centred distribution for sulphur and selenium atoms For the side of the cell (a) and density of hydrogen sulphide our values are also very similar $a = 5\ 778$ A (N), 5 76 A (V), density = 1 166 (N), 1 17 (V) For hydrogen selenide there is a certain quantitative difference $a = 6\ 020$ A (N), 6 10 A (V), density = 3 45 (N), 2 34 (V), as to the cause of which I cannot for the moment decide, and which I shall investigate further

For the distribution of the hydrogen atoms and the structure of the whole lattice, Vegard considers as most probable space groups T^4 or T_h^6 Considering both substances as ionic compounds, I regard as most probable the space group Oh^5, that is, a fluorite type, which is shown also by lithium sulphide (Claassen, *Rec Trav Chim Pays Bas*, **44**, p 790, 1925)

Viscosity of Electrolytes

IN NATURE of Dec 27 p 994, there are some general statements as to the viscosity of electrolytes, which are by no means universally true I refer to the statements that 'the relative viscosity of all electrolytes must be greater than unity at high dilutions", and that the phenomenon of 'negative viscosity' will disappear In a paper on the viscosity of aqueous solutions (*Trans Chem Soc*, vol 107, p 1789, 1915) the example of nitric acid is given and the relative principles are discussed It appears that the viscosities depend upon the mutual depolymerisation of the electrolyte and the solvent, and that the resultant behaviour depends on the temperature

At low temperatures, where a large proportion of trihydrol is present, the addition of the electrolyte breaks up so many of the ice molecules that even at high dilution the viscosity of the solution is reduced below that of water The subject is treated at length in the paper to which I have referred

Stellar Structure

THE investigation of the structure of the stars, which has for long been a subject of disagreement between Sir James Jeans and Sir Arthur Eddington, has now entered on a new phase through the work of Prof E A Milne A long paper on this matter by Prof Milne, which appears in the November number of the *Monthly Notices of the Royal Astronomical Society* together with related papers by Messrs R H Fowler, N Fairclough, and T G Cowling, was introduced to the Society in November last, but no time was available for discussion The whole of the meeting of the Royal Astronomical Society on Friday, Jan 9, was accordingly devoted to a debate on the subject, which was briefly opened by Prof Milne, and in which many astronomers and mathematicians took part

Prof Milne's views were outlined in NATURE of Jan 3, p 16 In opening the discussion, he stated that the pioneer work in the subject had been done by Sir Arthur Eddington, and what he himself had done was to rationalise Eddington's theory by clearing it of *ad hoc* hypotheses He could not accept Sir James Jeans's theory, because it depended on unlikely extrapolations of the laws of physics He considered that the mass luminosity law which Eddington claimed to have established was not a possible deduction from the fundamental formulæ It could follow only from the addition of a missing equation expressing the unknown dependence on physical conditions of the rate of generation of energy in stars He had, therefore, begun his investigations with observed quantities, representing conditions at the surface of the star, and had worked inwards, without making any assumptions unwarranted by observation

Sir Arthur Eddington, who followed, pointed out that disagreements in physical discussions could be of two kinds first, those which depended on the adoption of different assumptions or hypotheses in the absence of definite knowledge, and secondly, disagreements on the logical or mathematical deductions from given premises He thought that the disagreement between Sir James Jeans and himself was entirely of the first kind, but between Prof Milne and himself there appeared to be a mathematical disagreement, which was very unfortunate He did not approach Prof Milne's latest work in a spirit of opposition He regarded it as quite a permissible attempt to improve the existing theory in points where room for improvement undoubtedly existed The main feature of Milne's picture of the stars was that the mass was largely concentrated in a dense hot core with a surrounding rarefied envelope His own theory gave a much more gradual and uniform increase of density from the centre outwards For the sun it gave a central density of 70, whereas Milne's theory gave a value of about 700,000 The matter there was therefore, according to Milne, not in the condition of a perfect gas, and hence the mass luminosity relation could not be deduced There were certainly loopholes in that relation—it did not apply to a star composed mainly of hydrogen, for example—but he did not believe that Milne's theory had sealed up those loopholes Milne himself had confessedly not been able to satisfy himself that the equations for his stars possessed solutions, and Sir Arthur thought that it was *a priori* unlikely that they did If such solutions existed, however, it still remained to decide between the two widely different central densities This might be done by considering the intrinsic opacity in the interior, or its average if it was variable An appeal on this ground, however, would show that both theories were wrong—that was the long outstanding discrepancy between the physical and astronomical opacities of matter Both theories required a larger opacity than would follow from current physical theory, but he had found that the discrepancy on Milne's theory was far greater than that on his own A great deal depended on how large a mass was concentrated at the centre If it was merely a point source of extremely high temperature and density, with the rest of the star following a distribution of density almost identical with that of his own theory, he might be willing to accept the modification as a useful addition to that theory it would provide a source of stellar energy The large amount of mass, however, which Milne placed around the centre, inevitably made worse the existing discrepancy with regard to the opacity Prof Milne had objected to his theory being called a hypothesis, regarding it rather as an inevitable conclusion It was inevitable only if the premises were granted, and Sir Arthur had been denying them for fourteen years

Sir James Jeans found himself in almost complete agreement with what Sir Arthur Eddington had said, because Sir Arthur had not touched on the points on which they differed If Sir Arthur, Prof Milne, and himself all suddenly became infallible and omnipotent as mathematicians, he and Sir Arthur would still differ on the same points as before, but Prof Milne would agree with one or the other accordingly as he considered the stars to be gaseous inside or otherwise There was nothing new in Milne's theory, all that was accurate in it had been done previously by Eddington or himself He had shown long ago that if you integrated outwards from the centre of a star you got definite results right up to the boundary, but that there an infinite number of solutions were possible, and Nature itself decided which was the actual one When, therefore, Milne reversed the process by integrating from the boundary inwards, it did not matter with which of those solutions his initial data corresponded, he would necessarily arrive at the same conditions in the interior The work, however, would be much more cumbersome He agreed with Eddington about the opacity discrepancy, but considered that the case had not been put strongly enough The factor 10 in the luminosity, by which Eddington's own theory deviated from observation, was much greater than was permissible Expressed in terms of volume, it meant that the sun should be as big

as Antares Since Milne's theory made matters worse still, he considered that that theory was ruled out of court entirely

Dr W M Smart directed attention to the fact that the problem was an idealised one, since we knew nothing at all about the interior of a star from observation Assumptions had to be made, and it should not be forgotten that they were assumptions He considered the stars themselves were the final umpires in the matter Sir Arthur Eddington had suggested the opacity as the criterion by which the umpires gave their decision, he would suggest one of several other criteria Sir James Jeans's theory had been very successful in explaining the formation of spectroscopic binaries by fission, but he did not think that Prof Milne s centrally condensed stars would provide a satisfactory explanation

Prof F A Lindemann hoped that Prof Milne would maintain his theory, because it was the only one which gave really high temperatures in the stars The temperatures required by Sir Arthur Eddington were, on thermodynamical grounds, incapable of permitting the conversion of matter into radiation It was all very well to say that Milne's conclusions were inevitable only if you presupposed something Something had to be presupposed, and Eddington s *ad hoc* assumptions did not meet the facts of the generation of energy He considered that the discrepancy of a million fold in the densities of stars according to Eddington's theory was sufficiently large to make the increase to several million fold in Milne's theory of no significance in deciding between the theories

Sir Oliver Lodge remarked that what struck him most in the discussion was the remarkable agreement between the three protagonists They were agreed on knowledge of fundamental importance which was not available twenty years ago, and, in comparison with that, the differences were unimportant His idea of dealing with the problem would be to start with what we know—the surface temperature of the sun, its rate of generation of energy, the fact that energy comes from the disintegration of atoms Prof Lindemann had assured us that the last named process required a very high temperature Let that temperature at the centre be assumed Then we knew the relation between radiation pressure and gravitational pressure, and with regard to the opacity the Compton effect would give us some information From all these data a mathematician might work out some definite result He was fascinated by Milne's theory of a nova resulting from the collapse of a star Such a possibility had not occurred to him, but it seemed to work out

Several other speakers contributed to the discussion, which concluded with brief comments by Prof Milne He did not agree that his work covered the same ground as Sir James Jeans's He had started from the surface and worked inwards because it was only the surface that we could observe, and he had avoided assumptions which were necessary if you started in an unknown region

Although it could not be said that the discussion led to a greater measure of agreement between the various speakers, it undoubtedly helped, by bringing together different methods of dealing with the question, to focus the nature of the problem more clearly in the minds of those present

Vitamin B

VITAMINS B_2 AND B_3 BIOS

THE possibility of obtaining vitamin B_1 in a relatively pure condition has facilitated the differentiation of the other factors which, with B_1, make up the vitamin B complex Chick and Roscoe used Peters' concentrate to demonstrate that the rat required two factors, the second being known as B_2 or the antipellagrous vitamin More recently, they have published papers dealing with the chemical properties of this factor (*Biochem Jour*, vol 23, pp 504 and 514, 1929 vol 24, p 105, 1930)

Yeast extracts contain vitamin B_2, but the final antineuritic concentrate none examination of the by-products of the concentration showed that about half the B_2 was precipitated by lead acetate, in the treatment of the extract with this reagent (at pH 4 5) and another third in the treatment with baryta and sulphuric acid, the remainder being precipitated during the treatment with acid mercuric sulphate and the subsequent passage of hydrogen sulphide through the filtrate The lead acetate precipitate was the most convenient source for obtaining a concentrated preparation examination of this stage in detail showed that all the vitamin was carried down when the precipitation was carried out at a neutral reaction, but less than half at pH 2 6 The vitamin was recovered by decomposing the precipitate with hydrogen sulphide to ensure precipitation of the lead sulphide at an acid reaction, at which the vitamin is not adsorbed on the precipitate, it was necessary first to hydrolyse the yeast gum in the extract with hydrochloric acid Unfortunately, the lead precipitate also carries down some vitamin B_1, and it was not found possible to obtain a preparation of B_2 free from B_1 by dialysis, by making use of their different solubilities in alcohol or their different rates of destruction by ultra violet light The concentrate was active in a dose of 0 03 gm, equivalent to 0 5 gm dried yeast daily It is possible that yeast extract is an unsuitable medium for effecting a separation Rosedale (*ibid*, vol 21, p 1266, 1927) precipitated from rice polishings extract (by means of lead acetate) a factor which was not B_1, although enabling pigeons to grow and maintain health on a diet of polished rice It cannot yet be said with certainty, however, that this factor is vitamin B_2

B T Narayanan and J C Drummond have also carried out experiments on the concentration of vitamin B_2 (*ibid*, vol 24, p 19, 1930) Yeast

was extracted with dilute alcohol and the extract concentrated; lead acetate was then added, sometimes following a preliminary hydrolysis of the extract with baryta. The lead precipitate was decomposed with sulphuric acid, vitamin B_2 passing into the filtrate. It could be adsorbed on fuller's earth in strongly acid solution, but no satisfactory method of eleuting it again was found. Norite charcoal was not efficient as an adsorbing agent, and its use led to disappearance of the activity.

A certain amount is known about the properties of vitamin B_2: it is soluble in dilute, but insoluble in strong ethyl alcohol, and exposure to the latter results in its destruction. It is stable to hydrogen peroxide and nitrous acid and, to a certain extent, to heat, provided the reaction is acid. Autoclaving or even boiling at an alkaline reaction brings about rapid destruction. It is more easily destroyed by exposure to ultra-violet light than vitamin B_1.

Narayanan and Drummond examined a number of chemical compounds, including nucleic acid, purines, nicotinic acid, betaine and inositol, for vitamin B_2 activity, but all were, without exception, inactive.

V. Reader has adduced evidence that a third factor, tentatively called vitamin B_3, is necessary for the nutrition of the rat (*ibid.*, vol. 23, p. 689, 1929; vol. 24, p. 77, 1930). Animals kept on an apparently complete synthetic diet, in which Peters' concentrate supplied vitamin B_1 and alkaline autoclaved yeast B_2, failed to grow after some weeks; substitution of yeast extract for the two supplements led to an immediate resumption of growth. The failure did not appear to be due to lack of either vitamin B_1 or B_2, since increasing the amounts given did not improve growth. More convincing evidence of the existence of the third factor rests in the fact that it was found to be precipitated by the mercuric sulphate used in the preparation of the B_1 concentrate, and was recoverable, to the extent of 75 per cent of that present in the original extract, from the precipitate. Vitamin B_3 is even more easily destroyed by heat than B_1; under certain conditions it is soluble in ether. Rats fed on an ordinary diet carry a larger store of vitamin B_3 than of B_2; it is, therefore, possible that in short-time growth experiments, such as were used by Chick and Roscoe in the assay of B_1 or B_2, lack of B_3 does not play a part; again, it is also possible that antineuritic concentrates, unless highly purified, or autoclaved yeast, may be contaminated with traces of the third factor.

Chick and Roscoe found that vitamin B_2 was alone present in egg-white, but that rats on a synthetic diet with this material as source of the vitamin instead of autoclaved yeast, showed subnormal growth after a few weeks. They suggest that yeast contains a third B factor, which is, however, thermostable in contradistinction to Reader's B_3. M. A. Boas, some years ago, found that a diet containing dried egg-white produced skin lesions and nervous symptoms in rats, whereas fresh egg-white had no such effect (*Biochem. Jour.*, vol. 21, p. 712, 1927). A number of foodstuffs contained a factor which counteracted the ill effects of the ingestion of dried egg-white; it could not be identified with either vitamin B_1 or B_2.

The above account by no means exhausts the work which has been done on the chemistry of vitamin B. That three or four factors are included under this term appears certain, but it is not easy to relate the work of different investigators, especially when the claim for a new factor is based on the supplementary effects of different foodstuffs. Peters, in his Harben Lectures, reviews some of these investigations. Williams and Waterman found that pigeons maintained their weight on a polished rice diet when supplemented with marmite; transference to wheat, however, produced growth. Hence there is a factor in wheat which is absent from marmite and cannot be B_3. Hunt found that the residue of autolysed yeast, after thorough extraction with water, contained a factor which supplemented two obtainable from the extract; again this third factor does not appear to be B_3, which is soluble in water. Peters has also found that pigeons require for growth, in addition to B_1 and the factor of Williams and Waterman, a thermolabile factor which is present in yeast extract, and may be considered provisionally as identical with B_3; pigeons apparently do not require B_2. It appears, therefore, that the rat requires B_1, B_2, and B_3 with possibly Hunt's factor, whilst the pigeon requires B_1, B_3, and the factor of Williams and Waterman.

It may be of value to refer also to some recent work upon a substance which has been related by many observers to vitamin B, the yeast-growth stimulant or 'Bios'. Confusion was caused by the fact that it was not realised that different yeasts behave differently on various media, that their requirements for bios vary, and that the requirements of other micro-organisms need not necessarily be the same as those of yeast. Peters and his colleagues have investigated the growth factors required by *Streptothrix corallinus* (V. Reader, *Biochem. Jour.*, vol. 22, p. 434; with J. Orr Ewing, pp. 440 and 443; with R. A. Peters and H. W. Kinnersley, p. 445; 1928). When the organism was grown on a synthetic medium, a growth-stimulating factor was found in tryptic beef broth, yeast, rabbit muscle, serum, and wheat embryo; it is organic, soluble in water but not in ether, dialysable, and not precipitated by lead acetate. It accompanies vitamin B_1 in the preparation of the antineuritic concentrate but is stable to alkali in this concentrate (although unstable when crude) and is not, therefore, the same factor as the vitamin. It is synthesised by the *meningococcus*. It is not vitamin B_2. By parallel tests on the organism and on pigeons, it was shown that the factor and vitamin B_1 fractionate quantitatively together through all stages into the final concentrate.

The pitfalls encountered in such work are disclosed by certain anomalous results obtained with this organism, impure preparations of the factor sometimes appearing to contain relatively more growth-promoting activity when used in high concentrations than when used in lesser amounts. Reader has found that this effect can also be pro-

duced by adding mannitol to the purer extracts (*ibid*, vol 23, p 61, 1929) Mannose itself and related alcohols cannot replace mannitol, it appears that the organism uses the alcohol as a specific source of food supply

Working on the relation of bios to yeast, A M Copping (*ibid*, vol 23, p 1050, 1929) has found that the necessity for bios depends on the yeast and the medium used Those which grow in a synthetic medium without the addition of a factor such as is supplied by an autoclaved extract of yeast, produce a stimulant for other yeasts Bios is required by yeasts which only ferment and do not respire in its absence, added bios then stimulates both respiration and fermentation

Narayanan has separated a yeast bios from vitamin B_2 in yeast extract, since the former is not precipitated by lead acetate in the hydrolysed extract (*ibid*, vol 24, p 6, 1930) The bios is not adsorbed on norite charcoal, but is soluble in strong alcohol, it is precipitated by phosphotungstic acid but not by silver or platinic chloride By a series of fractionations a highly active concentrate was obtained The material contained nitrogen but no phosphorus most tests for nitrogenous compounds were negative, but a positive Pauly reaction was obtained It is stable to nitrous acid but destroyed by hydrogen peroxide Narayanan also tested a large number of pure substances, such as nucleic acid, purines, nicotinic acid, betaine, lipoids, and various bases and amino acids for bios activity, but all were found to be inactive

Henry Briggs, 1561–1631

HENRY BRIGGS died three hundred years ago, on Jan 26, 1631 He is famous for his important works on logarithms Napier's first publication of the invention of logarithms, in 1614, had come on the world, as Lord Moulton said, "as a bolt from the blue," breaking in upon human thought abruptly without borrowing from other workers or following known lines of thought Twenty years of persistent effort had been expended by Napier before he arrived at his great discovery, but within far less time than that after its publication the new method of computation was in use in England, France, Germany, and Italy, and its almost immediate adoption for astronomical and other calculations was mainly due to Briggs

Well over fifty years of age when he heard of Napier's work, Briggs made two visits to Scotland to see Napier, and the remainder of his life was almost entirely devoted to the compilation of his three works, "Logarithmorum Chilias Prima", 1617, "Arithmetica Logarithmica", 1624, and "Trigonometria Britannica", 1633 The first of these contained the logarithms of the first thousand natural numbers calculated to eight decimal places, in the second, he gave the logarithms of 30,000 natural numbers to fourteen places of decimals, while the third work, completed after his death by his friend Gellibrand, contained tables of logarithms of sines and tangents carried to the hundredth part of a degree and a table of natural tangents, sines, and secants The labours involved in these works have placed Briggs among the most industrious of men and the benefactors of mankind

Had Briggs never heard of Napier's invention and had he not taken a leading part in spreading abroad a knowledge of logarithms, he would still be remembered as one of the outstanding British mathematicians of his day, for he was the first to hold the Gresham professorship of geometry in London and the Savilian professorship of geometry at Oxford In a city rich in scientific associations the name of Sir Thomas Gresham (1519–1579) will always be connected with the foundation of the Royal Exchange and of Gresham College, from the latter of which, in other circumstances, might well have sprung a great university of London A visitor to-day leaving St Helen's Church—the Westminster Abbey of the City—where Gresham is buried, passes into a busy centre of finance and commerce Three hundred years ago it was not so, for just opposite the church stood the entrance gates to Gresham's mansion, which, by a will made in 1575, he bequeathed to the Mayor and citizens of London for the use of seven professors, who were to read daily lectures on astronomy, music, geometry, law, physic, rhetoric, and divinity Confirmed by an Act of Parliament, on the decease of Lady Ann Gresham the bequest became available, and in 1596 the chair of astronomy was bestowed upon Edward Brerewood (1565–1613), of Brasenose College, Oxford, while Briggs was appointed to the chair of geometry

Briggs was then thirty five years of age Born at Warleywood, near Halifax, Yorkshire, in 1561, he attended a grammar school in the district, and in 1577 entered St John's College, Cambridge He became a scholar in 1579, took the degree of B A in 1582, that of M A in 1585, and was elected a fellow in 1588 In 1592 he was made examiner and lecturer in mathematics, and for a time held the lectureship in physics founded by Linacre

Removing to London in 1596, like the other Gresham professors he occupied "commodious and comfortable" apartments in Gresham's house, and, with his colleagues, began delivering those lectures which were given, we are told, "to the great delight of many, both learned and lovers of learning" Some idea of Gresham's house, with its reading hall, its observatory, its galleries, its colonnade, and its great quadrangle, can be obtained from the sketch in Ward's "Lives of the Professors of Gresham College" For more than a century and a half it sheltered the professors and for half a century it was the home of the Royal Society, but to-day nothing of it remains The Royal Society removed its headquarters to Crane Court, at the other end of the City, in 1710, the interest in the lectures diminished, the buildings became dilapidated, and in 1767 "for the poor sum of 500£ per annum the trustees agreed to demolish the College and to part with all the land [the property really of the public] for the very unphilosophical purposes of an Excise office"

After this, lectures were given in the Royal Exchange until 1843, when a special building was erected and this in 1913 was replaced by the handsome Gresham College in Gresham Street, where the present Gresham professors continue the work which was inaugurated more than three centuries ago by Briggs and his fellow workers

In 1620, Briggs removed to Oxford as Savilian professor of geometry, at the invitation of Sir Henry Savile (1549–1622) Savile himself had already read thirteen lectures upon the first eight propositions of Euclid's "Elements", and Briggs began his own lectures with the ninth proposition His teaching, however, was of secondary importance to his compilation of logarithmic tables, and it was largely due to the leisure he enjoyed at Oxford that he was able to accomplish so much "A contemner of riches, and contented with his own station, preferring a studious retirement to all the splendid circumstances of life", his close habits of study did not prevent him gaining the good opinion of his contemporaries, one of whom, William Oughtred, called him 'the Mirror of the Age" Briggs's long and useful life came to an end when he was nearly seventy years of age, and he was buried beside Savile in the chapel of Merton College, "a plain Stone being laid over him, with his Name only inscribed on it"

Obituary.

DR J W EVANS, C B E, F R S

BY the unexpected death of John William Evans on Nov 16 last geological science has lost an indefatigable worker and writer, and many geologists a valued teacher, colleague, or friend Born in 1857 and educated at University College School and College, he took the LL B of the University of London and he was called to the Bar in 1878 He turned, however, to science and joined the Royal College of Science, where he studied under Judd and Cole, and was one of a brilliant group of students that included Holland, Wells Davies, and Lanchester He was awarded the Murchison Medal and joined the staff as demonstrator in 1889 He published his first paper in 1891, on the Old Red Sandstone of Caithness, a subject pursued again in later years, when he made important discoveries in the Devonian Rocks of southern England and made contributions to the classification of the rocks

In 1891–92 Evans was geologist to an expedition to the Upper Paraguay and other rivers in an almost unknown area in Brazil, later publishing a paper on the geology of Matto Grosso He returned to South America as leader of an expedition to north east Bolivia in 1901-2, and wrote descriptions of the area for the *Geographical Journal*, as well as geological papers

Meanwhile Evans had been appointed geologist to the State of Kathiawar, where he made important collections, afterwards described by himself or his students Then, in 1894, he passed to Mysore, becoming chief geologist and chief inspector of mines, etc In 1901 he received the Lyell award from the Geological Society, and about the same time took the D Sc of the University of London for a thesis on the geology of India

In 1904 Evans became special assistant in geology at the Imperial Institute, serving on the Colonial Survey Committee and Mineral Council of the Institute, posts which not only gave him the opportunity of acquiring a wide knowledge of the mineral resources of the Empire, but also a close interest in the personnel and work of the surveys This interest was enhanced by his appointment, later, as Colonial Office representative on the Imperial Mineral Resources Bureau, and here his legal knowledge was of much use in connexion with the improvement of mining codes in the Dependencies

From this time onward, Evans took much interest in mineralogy and crystallography, publishing papers on projections, classification, and nomenclature, on methods of investigation, and on the properties of certain minerals Much of this work was summed up in his own book on the determination of minerals under the microscope, and in his joint work on crystallography He was treasurer of the Mineralogical Society from 1918 until 1924, and afterwards foreign secretary until his death His teaching work was at the Birkbeck College from 1906 until 1920 and, as lecturer in petrology, at the Imperial College from 1912 until 1927 He was an inspiring teacher, and many of the students beginning research under his supervision have become leading geological surveyors or investigators

Dr Evans was a devoted adherent to the Geologists' Association, often leading excursions or contributing to the proceedings He was president in 1913 14, and dealt in his addresses with the wearing down of the rocks, a subject which his mathematical ability enabled him to treat in a fashion unusual and provocative of new work He was president of Section C (Geology) of the British Association at Bournemouth in 1919

The great War revealed a new side in Dr Evans's character His experience as a volunteer qualified him for a commission, and with the rank of lieut-colonel he was put in charge of a section of the northern defences of London He also served on the tribunal, was made a Justice of the Peace, and received the Volunteer Decoration

After being elected a fellow of the Royal Society, gazetted a C B E, and awarded its Murchison Medal by the Geological Society, Evans served in the presidency of the Geological Society during 1924–1926 Again he broke new ground and devoted his first address to the consideration of areas of tension in the earth crust, and the second to areas of compression About this time he became interested in the Wegener hypothesis, led a discussion on it at the British Association, and revised Skerl's translation of Wegener's book

Although petrology and mineralogy, and especi

ally their fundamental problems of genesis, were the main subjects to which Evans devoted his technical attention, his wide knowledge and critical acumen were constantly in evidence at meetings of many scientific societies, and particularly those dealing with geology and geography His contributions invariably brought up some overlooked fact, some unexpected point of view, or some novel theory or new application or an old principle It was the same with his letters and reviews in NATURE and other scientific journals

Before the War, Evans had got together a team of geologists to write the British volume of " Regionale Geologie ", to which he himself also contributed This was in type before 1914, and was actually published in Heidelberg during the War The copyright passed to England, and a revised edition has been brought out lately under his joint editorship and with the title of " Handbook to the Geology of Great Britain " He retired from the Imperial College in 1927 and took over the chairmanship of the Geophysical Company, for whom he visited the near East Evans rejoiced in every opportunity for travel, and for learning at first hand from the field itself or from the experiences of his colleagues there He was present at the last three International Geological Congresses, and after the last, at Pretoria in 1929, he travelled from the Cape to Cairo, visiting *en route* the various geological surveys, several of them run by his old pupils, inspecting their work, learning their problems, and inspiring them with new ideas Although to a man of his years such a journey was fraught with fatigue and some hardship, there was no suspicion that the end was near Indeed, when he returned to England in the spring of 1930, he travelled abroad again, and had planned a later visit to Palestine and Egypt

It is difficult to do justice to the work and career of so many sided a man, and this is a mere sketch of the chief of his work It may be said that while he left few branches of geology unstudied, he extended knowledge, improved methods, or clarified results in every division of the subject that he touched The simplicity of his character, the lovableness of his nature, his genuine interest and enthusiasm made him hosts of friends , while as for adversaries, if he had any, in the kindness of his heart he never realised their existence

PROF FRITZ PREGL

THE world famous Austrian micro chemist, Dr Fritz Pregl, died of pneumonia, after a very brief illness, on Dec 13 last Prof Pregl, who was sixty-one years of age when he died, was born at Laibach, a town which is now in Jugo Slavia but is less than 100 miles south of Graz, the capital of ' green Styria ', where he lived nearly all his life as student, research assistant, and finally as professor, the head of the Department of Medical Chemistry in the university He studied medicine—which in Austria comprises considerably more pure science than in most English medical schools—and after taking his degree, he chose rather physiological research than the practice of medicine He was appointed an assistant in the Department of Physiology in the University of Graz, and his first work was on the various organic constituents of the intestinal juice of a lamb, and a study of their digestive action, which he published in *Pflüger's Archives* in 1895

Prof Pregl's most important physiological work was on the acids in human and ox bile, of which cholic acid is the chief constituent He studied, so far as possible on a quantitative basis, their preparation, behaviour, and oxidation products, and built up that wonderful technique which was to enable him later to achieve success in more delicate quantitative organic determinations than had hitherto been considered possible

Prof Pregl's own words may be used to describe why he began his micro analytical work " In the summer of the year 1910, in the course of a lengthy investigation of the gallic acids, I obtained an extremely small quantity of a decomposition product I had to make a decision either to continue the investigation with exceptionally large quantities of the original material, or so to refine the quantitative analysis of organic substances that it should be possible to obtain correct analytical figures, from which formulæ could be determined with certainty, with exceptionally small quantities of material " He decided on the second alternative, with such success that by the end of 1911 he had worked out methods for the combustion of carbon and hydrogen, and a Dumas determination of nitrogen on a micro scale Since then he improved his methods and extended them to include all the commoner elements which may be present in organic compounds, as well as the determination of many organic groups The amount of material used in each determination is only a few milligrams, or about a hundred times less than on the ordinary or macro scale, but the same degree of accuracy is attained

As well as great skill in glass blowing—for Prof Pregl designed and made his own glass apparatus—the work necessitated extreme care and attention to detail, and it is interesting that in investigating the possible sources of error he was able to throw light on many hitherto unexplained errors obtainable on the macro scale In recognition of his services to science, Prof Pregl was awarded the Nobel prize for chemistry for 1923 The methods are described in his book, " Quantitative Organic Micro Analysis ", first published in 1917 , the third edition, completely revised, was published in the year of his death The book is written in a style as careful and accomplished as is his laboratory technique Prof Pregl, however, believed rather in the old tradition of learning by personal tuition than from practical manuals, and the hospitality of his laboratories has always been given to scientific workers from all over the world who wished to learn his methods In this way no less than three hundred chemists and biologists have learned his technique, and on returning to their own laboratories have developed and applied his methods to all branches of chemistry where economy of time or

material is of importance All who had the privilege of knowing him personally will remember him not only as a great scientific worker, but also as a charming man and a gifted talker, with an enthusiasm for his work that was contagious

The great importance of Prof Pregl's influence is that he stressed the fact that careful, accurate technique is the basis of all good scientific work, while his methods have made accuracy possible in realms where previously there were only rough approximations

DR HENRY M AMI

DR HENRY MARK AMI, who died at Menton, southern France, on Jan 4, aged seventy two years, was a well known geologist who had made valuable contributions to our knowledge of the Palæozoic rocks and fossils of Canada He was born in Geneva, the son of a Swiss Protestant clergyman who emigrated to Canada when he was a child He was at school in Ottawa, and thence proceeded to McGill University, where he had a distinguished career and came under the influence of the eminent Canadian geologist, Sir J William Dawson, who was at that time Principal of the University He graduated as M A and D Sc in 1882, and in the same year he joined the staff of the Geological Survey of Canada, from which he retired in 1912

During his official life, Dr Ami devoted special attention to the Palæozoic fossils of eastern Canada in the Survey Museum in Ottawa, and added greatly to the value of his researches by studying all the localities whence the fossils were obtained He also made frequent visits to Europe, especially to England and France, to compare the corresponding geological formations on the two margins of the Atlantic Ocean He was thus able to throw much new light on disputed questions as to the precise age and succession of the various rocks His researches on the Devonian and Carboniferous formations of Nova Scotia were particularly noteworthy

While occupied with his technical work, Dr Ami travelled extensively and took a deep interest in everything Canadian He was thus well equipped on his retirement from official duties to undertake the revision and partial rewriting of the volume on Canada and Newfoundland in Stanford's 'Compendium of Geography", which was published in 1915 During the War he did good service to the Government in advising on the source of metallic minerals, and was for some time connected with the Trade Department of the British Embassy at Washington During more recent years he was much handicapped by failing health, but from 1922 onwards he paid an annual visit to the Dordogne, France, where he directed the Canadian School of Prehistory, which he founded He took part personally in the diggings, which furnished fine collections of Palæolithic flint implements to many of the chief museums in Canada

Dr Ami was a familiar figure at scientific congresses, and his genial good nature won him a host of devoted friends on both sides of the Atlantic He was a fellow of the Royal Society of Canada and of the Geological and Royal Geographical Societies of London, and was awarded the Bigsby Medal of the Geological Society in 1903 A S W

MR W D CHRISTMAS

WILLIAM DURANT CHRISTMAS died at Peppard, Oxon, on Jan 3, at the age of sixty years Educated at Ellesmere College, Shropshire, he was at first a teacher, holding appointments at Haverford west and Rugeley His natural bent for figures found an outlet later when he joined a Stock Exchange firm During the War he joined the staff of the Rothamsted Experimental Station in a voluntary capacity, at a time when difficulties were being experienced in getting the work done owing to the absence of members of the staff on War service He assisted in keeping the records, and was particularly attracted to meteorology

After the War considerable expansion took place in the Rothamsted Experimental Station, and a Statistical Department was set up, Mr Christmas continued until his death as an honorary worker on the staff of this Department Aided by W C Game and A D Dunkley, of the regular staff, he undertook the compilation of the monthly weather records with great enthusiasm and abundant energy In letters to NATURE of Nov 3, 1921, and Jan 26, 1922, he directed attention to the abnormal conditions of the year through which we had been passing, a year which will be remembered for its record low rainfall He followed this up by contributing to the *Times* of Jan 26, 1923, a summary of the rainfall in 1922 This was the beginning of a regular series of letters which appeared in the columns of the *Times* at frequent intervals until the issue of Nov 3, 1930, when his last letter was published Besides rainfall, he dealt with percolation, sunshine, temperature, and related meteorological phenomena, such as fogs and storms

Mr Christmas had been in failing health for some years, and never recovered from the blow occasioned by his wife's death in 1929 But he kept up his Rothamsted work until his last illness, and it was a matter of deep regret to him that he was unable to contribute his customary summary of the year's weather to the *Times* on Jan 2, but had to entrust the task to another

WE regret to announce the following deaths

Prof S Henschen, professor of internal medicine at the Caroline Medical Chirurgical Institute, Stockholm, who carried out much research in anatomy and the pathology of the nervous system, aged eighty three years

Prof C von Monakow, of Zurich, one of the founders of modern neurology and author of "Die Lokalisation im Grosshirn", aged seventy-seven years

Prof J Ricard (S J), who was professor of mathematics and later director of the observatory of the University of Santa Clara, aged eighty years

Dr I Urban, assistant director of the Botanical Museum, Berlin, on Jan 7, aged eighty two years

News and Views.

PROF JOHN MACLEAN, of Wilson College, Bombay, writes in dissent from our article, "Administration and Research in India" (NATURE, Nov 22, 1930 p 797), to point out the danger of certain views on the Indian question current in England, among which he includes those we have expressed He maintains that Western education in India should not be criticised without allowance for misdirected effort, poverty of resources, and subservience to tradition Further, that no one thinks that self government will lead to peace and absence of friction nine months ago a fundamental change took place in India which has astonished the Indians themselves The Indian now claims to be regarded as a self respecting fellow man This has aroused the Indian woman Any assumption of superiority on the part of the Englishman, such as is now to be observed in London, will lead to ineradicable bitterness He asserts that gradual progress is not enough and that there is sufficient good will in India to warrant a leap in the dark He adds that the poll of the *Times of India* has shown that four out of five of the non official Europeans in Bombay are in favour of Dominion status Prof Maclean's criticism of our views trenches upon political arguments with which it would be out of place to deal here We may, however, point out in passing that the grant of a form of self government which admittedly will not lead to peace is perhaps a questionable improvement upon the *status quo*, but the fundamental change in India to which he alludes has not escaped attention in England He confirms the view that the situation is far more critical than is generally realised Be that as it may, these arguments do not affect our main contention The question of superiority does not arise it is difference of culture that counts In the future, even more than in the past, a satisfactory solution of Indian problems of government must be sought through the application of the results of scientific study of race and culture

THE truth of the matter is that the divergence of opposing views on the Indian question is so great as to make it difficult to find a common denominator which will afford a basis of discussion Prof Maclean sends us a report of an address on "Gandhi Politician and World Teacher", by Prof A Wadhia, as president of the Indian Philosophical Congress, in which he extols Gandhi as one of the world's great philosophers, a thinker who has transcended, or transformed, Hinduism and attained universality When Prof Wadhia turns to Gandhi's work as a political thinker and practical politician, the only concrete proposal is "Hind Swaraj" For Gandhi, Indian Home Rule is 'the ideal state' It must be remembered that Gandhi's philosophy is no mere intellectual system, but a 'way of life' It is the practical means of attainment, which, barely and baldly stated, have an element of bathos, that have laid him open to the charge of narrowness, casuistry, insincerity, and worse Even admitting the universality of Gandhi's philosophy—assuredly no product of intellectual or cultural inferiority—this is no warrant for allowing claims that would hand over control of the destinies of many millions to a comparatively small section, however much these claims may receive the doubtful support of pseudo scientific theory which seeks to show that India is virtually one in culture and race It may be that the trend of development in India is along the lines of Hinduism, but there are many who are and always will be outside those lines As we have already pointed out in these columns, an accurate knowledge and exhaustive study of the facts is required Only then can the claims of caste, outcaste, and depressed receive fair and equal treatment

ON Jan 14 the freedom of the Borough of Bangor was conferred on Dr Griffith Evans, who, fifty years ago, was inspecting veterinary surgeon to the Government of Madras In then discovering the first pathogenic trypanosome he laid bare the cause of a disease which was causing havoc amongst the camels and horses of the Punjab Frontier Force Although the senior medical officers in India were definitely opposed to the theory of pathogenesis advocated by Dr Evans, the younger men have followed with success the lines of investigation he indicated He thus opened a campaign, which still continues, against what is now recognised as one of the most destructive groups of disease producing organisms with which science has to contend Tetanus was another field in which Dr Evans showed his power of original thought At Ipswich in 1870 there was a bad outbreak of the disease, in which every case had proved fatal Being invited to a consultation, he gave his view that the disease was a specific fever for which there was no known specific remedy Arguing from his experience of the disease in horses, he urged that the treatment should be rest in a dark, silent room, no noise from without or within, no food of any kind nor any medicine, but let the patient drink water *ad lib*, and leave the rest to Nature Accepting responsibility for the treatment of the case of a child, he had the full courage of his convictions, and the case recovered At the age of ninety six years, Dr Evans still retains his mental activity

LITTLE direct news has come through of the earthquake that was so destructive in the south of Mexico on Jan 14 That it was a great earthquake is shown by the record at Kew The first movements reached that observatory at 2 h 2 m 59 s A M on Jan 15, and the earthquake that gave rise to them must have occurred in Mexico at about 9 P M local time on the previous evening The earthquake is said to have been the most violent experienced in the country since 1911 The epicentre was probably close to the City of Oaxaca, which has been almost completely destroyed, with the loss of at least 40 lives The extent of the disaster may, however, remain for some time unknown, owing to the wide interruption of communications How great it was is clear from the fact that there was also considerable damage in the City of Mexico, 230 miles from Oaxaca In the south of the country, there are numerous well defined earth-

quake centres, one of the most important of which lies in the district round Oaxaca That city suffered twice from earthquakes in 1928, on June 16 and Oct 9 (NATURE, vol 121, p 994, and vol 122, pp 68, 620), but the epicentres then were both submarine, at some distance from land On Jan 2 (*Daily Science News Bulletin*), a strong submarine earthquake occurred with its centre in lat 17 8° N, long 108° W, several hundred miles to the west of those in 1928

ANOTHER step forward has been taken in making navigation safer during a thick fog We learn from the *Times* of Jan 13 that the Clyde lighthouse trustees have put a talking beacon in the Cumbrae lighthouse, and that instructions have been given to mariners regarding its use It is the first device of the kind in the world It consists merely of a radio gramophone used in conjunction with the lighthouse foghorn By this means the radio operator on the ship is told exactly how far his ship is from the lighthouse The record played on the lighthouse gramophone is simply the name of the beacon in speech (Cumbrae) repeated every 70 seconds, and numbers counted in miles and cables up to five miles These signals are transmitted by radio There is then an interval of silence of 27 seconds until the name Cumbrae is heard again and the counting recommences The signals of the foghorn are heard directly The difference in the times of hearing the word Cumbrae and the foghorn is practically equal to the time taken by sound to travel this distance, and so the gramophone numbers give the distance Actual tests have been carried out on this device by ships of the Anchor line and were found quite satisfactory The 'talking beacon' was invented by C A and D A Stevenson, of Edinburgh, the connexion of whose family with lighthouses is well known to every reader of R L Stevenson When vessels are equipped with this device, which is quite cheap to install, they will have a good idea of their distance from other ships, thus avoiding one of the causes of collision at sea While the apparatus is still in its infancy, the trustees have warned mariners to take, in addition, the usual precautions during fog

NEARLY all the peculiar phenomena which are experienced in radio transmission can be explained by supposing that the radio signals travel from one station to another by more than one route The direct line of transmission is usually one of these paths Very often the greater part of the signal which we hear has travelled to the upper regions and back, and constitutes what is called a wireless echo In the *Wireless World* for Jan 7 and 14 Prof E V Appleton gives an interesting paper on the timing of wireless echoes, and suggests alternative theories of the Kennelly Heaviside layer The time taken to traverse the different paths is known definitely, and guesses are made as to what these paths are The first experiments on the timing of the journeys of radio waves were carried out almost simultaneously in Great Britain and the United States It was assumed that there was a conducting layer, and the English experiments placed its height as about 100 km On the other hand, the American experiments indicated a height of about 220 km Whilst the wave length used by the English physicists was 400 metres, that used by the Americans was 75 metres On repeating the English experiments with wavelengths of 75 metres, it was found that the height deduced for the conducting layer was the same as that found by the Americans There was a certain critical wave length at which the echo time suddenly doubled There is therefore definite evidence that there are two reflecting layers at different heights, the lower sending back the long waves and the upper sending back the short waves In the second part of his paper Prof Appleton discusses the effects that these short period echoes will have in radio picture-telegraphy and in radio television

IN a paper on "Recent Developments in Telephony", read by Dr E H Colpitts at the Cleveland meeting of the American Association for the Advancement of Science, a summary of which appeared in the *Daily Science News Bulletin* for Dec 30, it was stated that the plans for a Hawaii California telephone circuit are now well under way Hawaii is very centrally situated, as it is roughly equidistant from North and South America, Asia, and Australia A short wave station will be established to communicate with Honolulu, and another radio link from a point on the Atlantic coast to Bermuda is also planned Radio stations of limited range are being established at several of the principal ports They are equipped so that communication with ships at sea can easily be made This extends the service given by liners like the *Leviathan*, which, at present, is in telephone communication with the shore all the way across the Atlantic Although radio has made huge advances of recent years, it is still not so trustworthy as a submarine cable A trans Atlantic telephone cable is now being prepared When completed it will be connected with about 2000 miles of land cable in Europe It will thus be possible from Hawaii to talk over about 7000 miles of wire Surprise was expressed that no mention was made of the work done by the Bell Telephone laboratories on television, as recently two way television was shown to be possible in New York This is interpreted as meaning that the commercial application of television is still in the distant future

ONE of the earliest writers on marine engineering spoke of the boiler as "the source and magazine of all our power", while another referred to it as "the fountain head from which all benefit is derived" These remarks were made when the ordinary steam pressure at sea was but 5 lb per sq in, but they apply equally well to day when pressures have risen to 400 lb and 500 lb Recent progress in marine boilers is among the subjects dealt with in the *Engineer* for Jan 9, in which are given illustrations of the latest designs of the well known Yarrow and Babcock and Wilcox boilers for high pressures and temperatures Another boiler is that recently designed by J Johnson, the superintendent engineer of the Canadian Pacific Steamships, Ltd In some ways the Johnson boiler is a new departure, there being only two drums, an upper and a lower one, and these are joined by

tubes bent to crescent form bulging out either side of the centre line of the boiler. Other tubes run vertically between the drums, and still more tubes form water walls at the end of the boiler. The furnace spaces are thus practically enclosed by walls of water tubes. Tried first in the *Princess Helene*, another boiler has been built for the *Empress of Britain*, and a test of this 10,000 h.p. boiler showed that at mercantile ratings and for the same efficiency it will yield, for the same weight of boiler and air heater, double the output of the three-drum water tube boiler. One feature of the boiler is the use of air for combustion preheated to 500° F.

IMPORTANT statistics regarding the production of rubber were given in a paper read on Jan. 13 by Dr. G. Rae, at Birmingham, to the Midland Section of the Institution of the Rubber Industry. The total area under plantation rubber at the end of 1929, he said, was between 6,600,000 acres and 7,200,000 acres, of which the area under native rubber in the Dutch East Indies was variously estimated at between 1,100,000 acres and 1,700,000. About 3,360,000 acres were in estates owned by Europeans and Americans; 510,000 acres in Asiatic owned estates of more than 100 acres, and 1,630,000 acres in native holdings of less than 100 acres. The total exports of rubber from producing countries were 94,000 tons in 1910; 354,000 tons in 1920; 518,000 tons in 1925, and 861,000 tons in 1929. The output for 1930 was 820,000 tons. Of the output in 1929, British producers were responsible for 36 per cent, Dutch and other European producers 10.2 per cent, and American producers 2.6 per cent. The absorption of rubber by manufacturers (that is, the quantities of rubber they turned into rubber goods) was 85,000 tons in 1910; 310,000 tons in 1920; 560,000 tons in 1925; 790,000 tons in 1929, but would be approximately only 705,000 tons in 1930.

THE United States Department of Agriculture has published a booklet, written by Prof. A. J. Henry, Principal Meteorologist, Weather Bureau, entitled "Weather Forecasting from Synoptic Charts", which deals primarily with American methods of weather prediction. These are described in considerable detail. They are of interest in showing, among other points, the specialised methods that have been developed for dealing with the requirements of particular sections of the agricultural community, and the arrangements for issuing storm warnings. There is no other country that has to deal with such violent fluctuations of temperature in a short time and with such possibilities of financial loss involved in consequence of them, and that has also to take into account possibilities of locally destructive tornadoes and of tropical revolving storms that may cause the loss of thousands of lives, in addition to gales arising as a result of the eccentricities of an exceptionally lively portion of the storm belt of middle to high latitudes, where anticyclones have the peculiar characteristic of a mean rate of travel approximately equal to that of depressions. It is not surprising to find that an unusually extensive development of the system of local forecasting has taken place, and that it has apparently met with great success. This system involves the delegation of forecasting for single States, and even in some instances for parts of one State, to forecasters resident within the area allotted to them having authority to amplify or modify the deductions about future weather made at the central bureau in Washington. Such forecasters construct their own synoptic weather maps, and doubtless employ a closer network of stations than can be dealt with at the central bureau, gaining thereby a special knowledge of local conditions. The booklet is intended primarily for home use. It is, however, an important addition to European meteorological libraries and deserves careful study on this side of the Atlantic when the creation of new meteorological services or the enlargement of existing ones is under consideration.

IN the *Časopis Společnosti Přatel Starožitnosti Československých* Dr. O. Odložilík has traced a letter written by the medieval pedagogue, Jan Amos Komenský (Comenius), dated Mar. 4/14, 1647, relating to the exile of himself and the engraver, Vaclav Hollar. Komenský expresses his regret that circumstances forced them to leave home through the religious persecution of the counter-reformation. Dr. Odložilík comments upon the work and influence of these Czech scholars on contemporary thought. Komenský conceived the idea of making a survey of all human knowledge, which was even then becoming more and more extensive owing to the development of the natural sciences. He began the compilation of a kind of encyclopædia where knowledge was to be arranged under twenty-eight sections. Only a fragment of this work remains. He attempted a definition of the most intrinsic and general features common to all created things thinking that if this could once be achieved it would be easy for him to indicate the way to a knowledge of details. Knowledge might be infinitely differentiated and divergent so long as a common foundation could be established, such as would assure a steady progress in science. These ideas of Komenský were first outlined in a work which appeared in Oxford in 1637 under the title "Conatuum Comenianorum Præludia". Although his views impressed and influenced those English men of science who later were instrumental in founding the Royal Society, Komenský's pan-sophic schemes and educational programmes could scarcely succeed during his lifetime. There was civil war in England and the Thirty Years' War was devastating Europe. Nevertheless much of his teaching has since borne fruit.

THE fifth volume of the annual summary of scientific and economic research work in agriculture, entitled "Agricultural Research in 1929", has been published by the Royal Agricultural Society of England (price 1s. 3d. post free). This publication has now established for itself a definite place in the periodical literature of the farming industry, and should be studied by all those wishing to keep themselves abreast of modern agricultural practice. The various branches of agriculture are considered under seven main headings as in previous years. The information covers such a wide field that it is impossible to do more than indicate some

of the many interesting and important subjects considered. The recently developed tar distillate sprays for fruit trees are discussed in some detail, and it is evident that as winter washes they are extremely effective against many insect pests. For the arable farmer, the articles on varieties of sugar beet, and the control of rust and smut diseases of cereals, in which practical methods with relative costs are included, will be of particular value. As regards dairy husbandry, fundamental problems such as breeding and management of cattle, milking methods, and the interpretation and use of milk records are considered. For those interested in engineering questions, articles on the use of electricity, traction, and the development of some of the newer farm implements are included. Feeding values for dairy cows and pigs are the chief subjects on animal nutrition discussed, the importance of minerals in stock feeding being emphasised, and it is evident from the section on veterinary science that considerable advances have been made in the control of contagious abortion and tuberculosis. Under the heading of soils and fertilisers, soil classification and methods of land reclamation are discussed, and data as to the world production and consumption of the chief fertilisers are given, the use of nitrogen and potash in particular showing a large increase. Each section concludes with a list of papers quoted.

"THE Mechanism of Organic Evolution" was the subject of an address by Charles B. Davenport, to the Washington Academy of Sciences, which appears in the *Journal* of the Academy (vol. 20, p. 317, 1930). After revising some of the recent observations on the occurrence of mutations, their direction, and their natural selection, he summarises the mechanism of organic evolution as consisting of a series of processes: infinite capacity of the germinal material for reproduction; infinite capacity for mutation; an infinitude of different kinds of environments; extensive opportunities for dissemination of the mutant individuals over the earth, permitting some of them to find an environment for which they are specially fitted; as for the rest of the infinitude of individuals, non-mutant and mutant (beyond the number required for replacement), elimination. The organic world is far from being the infinitely diverse collection of haphazard and meaningless variants to be expected if mutations were uncontrolled. The directive influence, according to the author, appears to work through the repeated losses of something from the parental gene. This may be true of the cases Davenport selects, albinism, hairlessness, and the like, but our difficulty is to see how, looking broadly at the products of evolution, loss in the gene can mean greater complexity in the final product—in short, how the organic progress from amœba to man can be due to successive losses in the germinal content.

ONE of the most significant of the articles in the September-October number of *Natural History*, the journal of the American Museum of Natural History, discusses "The Museum in Education". The sub-title contains the challenge and gist of the argument: "the unparalleled present-day opportunity [of museums] to serve the community and to participate in the rapidly advancing movement for visual instruction". The way in which the American Museum of Natural History takes its share in this movement sets an example to be emulated. We need simply enumerate the museum educational activities to show their thoroughness and diversity. The extra-mural activities of museum service in the schools and colleges include circulation of nature study collections, lending of lantern slides, distribution of motion picture films, lectures in schools, lending of circulating collections to branch libraries, co-operation with nature rooms in schools, and the Trailside Museum and Nature Trails at Bear Mountain. The intramural activities of school service at the museum comprise lecture courses in the museum, instruction for the blind, exhibition hall instruction and guidance for visiting groups, the Junior Astronomy Club, special courses for teachers, adult education, and co-operation with the training schools for teachers, high schools, and colleges.

A RECENT issue of the scientific journal *Physis* (vol. 10, No. 35), the publication of the Natural History Society of Argentina, contains a series of valuable papers on the structures of mammalia. Two papers discuss the fossil mammals of various parts of South America. From the pampean fauna of Patagonia, Lorenzo J. Parodi describes several interesting relics, including a new species of *Megatherium* of which a fine skull has been discovered, a portion of a carapace of *Glyptodon*, and phalanges of *Mylodon*. From the Friaseana beds of mid and lower Miocene, Lucas Kraglievich describes an extensive fauna, containing many new species of mammals, which he regards as a transitional association connecting the definite faunas of Santa Cruz on one hand and of Entre Rios, Catamarca, and Monte Hermoso on the other. An aspect of the evolution of the present day mammalian fauna is dealt with by the same author in a useful paper on the craniometry and classification of South American wild dogs, in which he refers specially to the recent and fossil forms found in the Argentine. Finally, Rodolfo Parodi makes a contribution to the osteology of the larger living felines of the Argentine, the puma, the jaguar, and the ocelot.

WE have referred previously to Research Narratives published by Engineering Foundation, Inc., 29 West 39th Street, New York, which have been published in book form. By the courtesy of the Director, Mr. A. D. Flinn, we have now received copies of some further Narratives as they are first published, month by month, in leaflet form. Many leaders in finance, industry, engineering, and education, we are told, have these sent to them regularly in this convenient form, the leaflets being of such a size as can be slipped into a pocket book or wallet so that they can be read at a convenient moment. Of those issued last year, that for April was on isotopes; that for June, on pressure and matter; that for August, on short-wave high power radio tubes; while that for September contained an interesting account of the ingenious method adopted for damming the Saguenay River about 140 miles

north of the city of Quebec, where a mass of concrete, 92 ft high and about 45 ft square in section, was built upright on the bank of the river and then allowed to fall across the stream

THE centenary of the birth of James Clerk Maxwell is to be celebrated in the University of Cambridge on Oct 1 and 2, following on the Faraday celebration and the centenary meeting of the British Association in London Addresses are to be given at Cambridge by Profs Einstein, Langevin, Larmor, Planck, Sir James Jeans, and Sir J J Thomson

MR W A MACFADYEN, Longships, Capel le Ferne, Folkestone, has written objecting to the spelling in the letter by Dr C Crossland in NATURE of Dec 27, p 991, of the place Ghardáqa He urges that since the Anglo Egyptian Oilfields, Ltd, drilled the first oil well there in 1914, the spelling Hurghada has been used, and this form is also used officially by the Egyptian Government for the post and telegraph services It would appear, however, that the name is correctly Ghardaqa, pronounced locally with the regular accentuation on the first syllable, writing from Cairo, Dr Crossland would put the accent on the second syllable The form Hurghada is supposed to be easier for Europeans to pronounce, but it is incorrect and phonetically distasteful to Arabic scholars

MR JAMES DRUMMOND, of Christchurch, New Zealand, who, at the age of sixty-one years, has retired from ordinary practical journalism, for a long time has successfully combined work on a daily newspaper with natural history Interested in the botany, zoology, and geology of his own country, and realising that in the newspaper Press he had a unique means of passing knowledge on to the public, he seriously and earnestly took in hand an educational work in this direction Every week for twenty five years he has published a popular natural history article in a syndicate of leading New Zealand journals, with very gratifying results, evidenced by many expressions of appreciation He has also published a number of books on New Zealand natural history, of which the most important, "The Animals of New Zealand", was written in collaboration with the late Capt F W Hutton and is in its fourth edition Mr Drummond has published books on other subjects, but now intends to devote his literary activities to the natural history of New Zealand

THE annual general meeting of the Institute of Metals will be held at the Institution of Mechanical Engineers on Mar 11 and 12 under the presidency of Dr R Seligman, the programme includes fourteen papers on various aspects of non ferrous metallurgy It is also announced that the May lecture of the Institute will be delivered on May 6 by Mr W B Woodhouse, of the Yorkshire Electric Power Company, who will deal with the technical and economic progress in large scale electric power generation The annual autumn meeting of the Institute will be held in Zurich on Sept 13 16, immediately following the meeting of the International Association for Testing Materials

THE Council of the Geological Society has this year made the following awards Wollaston Medal to Dr A W Rogers, of the Geological Survey of the Union of South Africa, in recognition of the value of his work on the geology of South Africa Murchison Medal to Dr G W Tyrell, of the University of Glasgow, for his work on the igneous rocks of the west of Scotland Lyell Medal to Mr E C Andrews, of the Geological Survey of New South Wales, for his researches on the economic geology of New South Wales and on physical geology Bigsby Medal to Dr Norman L Bowen, of the Geological Laboratory, Carnegie Institution, Washington, D C, in recognition of the value of his researches on the physical chemistry of igneous rocks Wollaston Fund to Dr R G S Hudson, for his work on the stratigraphy and palæontology of the Carboniferous rocks of Yorkshire Murchison Fund to Dr C J Stubblefield, for his researches on the Cambrian rocks of Shropshire and on invertebrate palæontology A moiety of the Lyell Fund to Dr O M B Bulman, in recognition of his work on the Cambrian rocks of Shropshire and of his palæontological researches, and a second moiety of the Lyell Fund to Mr W H Wilcockson, for his work on petrology and economic geology

WE have received from Science Service, Washington, a brief account of the demonstration by Dr George W Crile, at the recent meeting of the American Association for the Advancement of Science in Cleveland, of what he calls "autosynthetic cells" Dr Crile brought together certain proteins, lipoidal brain extracts, and mineral salts in small cavities on glass slides, and in a few seconds the materials arrange themselves into masses showing certain resemblances to various types of unicellular organism Among these resemblances are cited nucleation, growth and division by fission and budding, respiration, stainability, motility, and electric charge, they disintegrate when the difference of potential between 'cytoplasm' and 'nucleus' reaches zero The addition of narcotics and anæsthetics causes a decrease in potential and in respiration, which are reduced to zero under the influence of cyanides and toxins These structures have been kept in 'life' for ten weeks by the repeated addition of protein to the 'culture' The experiments, so far as reported, suggest that certain mixtures of colloidal and other substances may be induced to arrange themselves into structures exhibiting some of the properties, both morphological and physiological, of living cells Various experiments with irradiated proteins and lipoids, and with these substances derived from cancer cells, are also mentioned

THAT chlorophyll and hæmaglobin are analogous organic compounds, which can be reduced to the same type of pyrrole derivative by removal of the metal—magnesium in the case of chlorophyll, iron in the case of hæmaglobin—and further treatment, has been well known since the classic researches of Willstätter upon chlorophyll It is very interesting to learn, therefore, that liver extract, successfully used to check the course of pernicious anæmia in human beings, has now been used by Prof O Raber to check the yellowing of given plants grown under etiolation conditions Prof Raber's experiments were reported to the

American Society of Plant Physiologists meeting in Cleveland, U S A, according to a report received through Science Service, of Washington, D C

YEAR BOOK No 28 of the Carnegie Institution of Washington contains a series of brief but interesting "Reports on Investigations" from the Department of Embryology under the directorship of Dr Streeter It is not possible to mention all the reports, covering as they do such a wide field, from more or less straight forward embryology to experimental work, pathology, and tissue culture Certain reports, however, seem of wide interest Drs Gregory and Lewis have succeeded in making a kinematograph record of the developing rabbit's ovum from the first cleavage up to the formation of the cleavage cavity Dr Hartman has worked out the rate of intra uterine and post-natal development of the opossum in considerable detail, and alone and in co operation with colleagues added much to our knowledge of the phenomena associated with reproduction in *Macacus rhesus* Dr Hines has produced a monographic study of the brain of *Ornithorhynchus*

APPLICATIONS are invited for the following appointments, on or before the dates mentioned — A science master and a master for engineering subjects (mechanics, machine drawing, and engineering science) in the Junior Technical School for Boys of the North Western Polytechnic—The Secretary, North Western Polytechnic, Prince of Wales Road, N W 5 (Jan 30) A laboratory assistant at the L C C Shoreditch Technical Institution—The Education Officer (T 1), The County Hall, S E 1 (Jan 31) An assistant radiologist at the Hospital for Tropical Diseases, Endsleigh Gardens — The Secretary, Seamen's Hospital Society, Greenwich (Feb 4) A professor of educational psychology in the Egyptian Institute of Education — The Director, Egyptian Education Office, 30 Victoria Street, S W 1 (Feb 9) A director of the Gardens of the Royal Horticultural Society, Wisley—The President, Royal Horticultural Society, Vincent Square, S W 1 (Mar 2) A professor of zoology in the Queen's University of Belfast—The Secretary, Queen's University, Belfast (April 30) A lecturer in agriculture in the University of Reading —The Registrar, The University, Reading An assistant lecturer in mathematics and demonstrator in physics or chemistry at Faraday House Electrical Engineering College—Dr A Russell, Faraday House, Southampton Row, W C 1

Our Astronomical Column.

Eros —Prof Hartmann makes a bold suggestion in *Astr Nach*, 5762, to explain the twofold fact that Eros deviates considerably from the predicted ephemeris, and that it is about a magnitude fainter than was expected He notes that even before the present apparition the peculiar curve of light variation had caused the suggestion to be made that the planet was shaped like a dumb bell He now suggests that Eros has broken into two portions, of which the one now under observation is the fainter If anything of the nature of an explosion accompanied the separation, the two portions would drift apart, thus explaining the error of the ephemeris The suggestion is ingenious, but there are two grave objections

(1) If the fragment under observation is the smaller one, the other would be closer to the predicted place, and could not well have escaped detection on the numerous plates that have been taken

(2) The splitting in two could scarcely leave the rotation period unaffected The light curve now obtained agrees, both in period and type, with the observations made in 1901, which is against any notable change having taken place since then

Planetary Nebulæ and *O* type Stars —A note in the Astronomical Column of NATURE of Feb 1, 1930, p 180, referred to an article by Prof C D Perrine in *Astr Nach*, 5672, on the radial motions of the *O* type stars The note suggested that there was some difficulty in reconciling the two suggestions of Prof Perrine (1) that planetary nebulæ are the relics of former novæ, (2) that planetary nebulæ and the *O* and *B* type stars form a progressive series of objects The idea in the reviewer's mind was the distinction between the catastrophic development of novæ and the apparently steady condition of the *O* and the *B* stars In a letter to the Editor, Prof Perrine now suggests that we have little guarantee of the permanence of spectral types he says, "even to day stars other than novæ are under suspicion of having changed type appreciably" Further, he notes that the spectra of novæ pass in succession through various spectral types, and that a nova the development of which was unusually slow might be classified as a normal *B* type star while it was passing through this stage Prof Perrine further notes, in amplification of his former paper, that he has now applied the radial motion due to galactic rotation, as given by Plaskett's observations, to his results for the *O* type stars "These are made more consistent, strengthening the assumption of a systematic difference between the absorption and emission stars"

Sydney Astrographic Catalogue —The Sydney Observatory is making great efforts to catch up its serious arrears in publishing its section of the astrographic catalogue, which extends from 51° to 65° S Decl It will be published in 52 sections, each covering 6 hours in R A and 2° in Decl, each region of the zone appearing on two plates at least Volumes 11 and 12 have recently been issued, they include the plates the centres of which lie in Decl 54° S, and R A from 12^h to 18^h, and 18^h to 24^h respectively Vol 11 contains 86 pages, and Vol 12 43 pages, a full page contains 280 stars, but many of the pages have blank spaces The lower galactic latitude in the region of Vol 11 explains its greater star density The following volumes of the Sydney catalogue have now been published 1 to 8, 11 and 12

The method of denoting magnitude has not been uniform in these volumes the earlier ones use a scale of letters, the later ones substitute the numbers, 1, 2, 3, etc, for the letters *a*, *b*, *c*, etc The magnitude column is headed "Diameter", which is rather misleading, as numeral 1 denotes the brightest stars, of magnitude about 8 0, and therefore the largest diameters, while 10 denotes those that are just perceptible, magnitude about 12 2 For stars brighter than mag 8 the actual diameter, in thousandths of a reseau interval, is given The dates of exposure of the plates are mainly between 1892 and 1900, but a few are so late as 1925 The *X* and *Y* co ordinates are given to the third decimal of a reseau interval It is noted that up to the year 1912 the plates were measured at Melbourne, but since that date, at Sydney.

Research Items.

The Bundle of Life.—In *Ancient Egypt*, 1930, pt. 3, Miss M. A. Murray brings forward evidence from ancient Egypt in support of Sir James Frazer's contention that the expression 'bundle of life' used by Abigail when addressing David is a reference to the doctrine of the external soul. As the well-being of the whole country depended upon the life and soul of the Pharaoh, every effort was made to protect them from accident or illness. The royal soul would be completely safe if wrapped up and entrusted to the safe keeping of a special official whose life terminated with the life of the king. The object so wrapped up and guarded might well be known as the 'bundle of life.' The placenta and umbilical cord are peculiarly important to primitive minds, and it seems that among certain peoples the placenta or the cord was regarded as the seat of the external soul. It has been pointed out that a certain standard carried before the Pharaoh on ceremonial occasions represented the royal placenta. The beliefs and practices of the Baganda in regard to the royal umbilical cord appear to afford close parallels to Egyptian ritual of the early historical period. In the early period of Egypt the actual object was represented; but later it became highly conventionalised, because the artist was accustomed to see the object in wrappings only. In Uganda the object was entrusted to a high official, ranking next to the Prime Minister; in Egypt it was entrusted to the Prime Minister himself, who was also the chief magician. The rare title in Egypt for which the translation "the Opener of the Placenta" is suggested, would then refer to the death of the king by the opening of the 'bundle of life' to release the soul. This officer would then be the executioner of the king when his divine powers began to wane. The custom was still remembered in the sixth dynasty, though a victim had then been substituted for the royal sacrifice. The title became extinct at the end of the Old Kingdom, but in the New Kingdom the object reappears in temple wall sculptures, plaques, etc.

Chiefs and Shamans in California.—Mr. A. H. Gayton has made a study of the functions of chiefs and shamans respectively in the social organisation of the Yokut and Western Mono of the San Joaquin Valley of southern central California, which is published as No. 8 of vol. 24 of the *University of California Publications in American Archæology and Ethnology*. The political organisations of Yokut and Mono were as simple as any among Californian tribes. They had no clans, and the moiety regulated marriage and participation in ceremonial observance. Patrilineal families dwelt in permanent villages; but they owned no land other than an ill-defined tribal area. They lived by hunting, fishing, and food gathering. Truthfulness, industry, and generosity were not so much virtues as necessities. Legal authority was wielded by the chief, with the winatums as executive officers and go-betweens from the authority of the chief to the people. The chief made decisions on tribal and inter-family affairs, such as fandangoes and mourning ceremonies, the building of a sweat-house and so forth. He gave permission for the infliction of the death penalty. There was a complete absence of formulated law; each case was taken on its merits by the chief, who gave his decision without reference to precedent. Peace and public satisfaction were secured by a power which had no legal basis—the fear of sorcery. The peace of the community depended upon the character of each individual, and this was moulded by the fear of supernatural powers, which could be brought into operation by the individual himself or by a shaman hired for the purpose. Such transgressions as cheating in gambling, adultery, or neglect of any ceremonial duty, by these means would be visited on the offender or a member of his family. The shaman through whom the penalty for transgression was inflicted was not an official. Nevertheless he acted in co-operation with the chief, who utilised his services in punishing an individual who did not take his part in carrying out any public duty, such as contributing his fair share to a fandango, mourning ceremony, or the like. A check was kept on both the shaman and the chief by the fact that oppression or unfairness on the part of the chief, or trickery or abuse of his function by the shaman, would be punished by exposure, loss of influence and position, and even death.

Leonardo da Vinci as Anatomist.—In his recent excellent monograph entitled "Leonardo da Vinci the Anatomist (1452–1519)" (Publication No. 411 of the Carnegie Institution of Washington. Baltimore, Md.: Williams and Wilkins Co. 6 dollars), Dr. J. Playfair McMurrich, professor of anatomy of the University of Toronto, has given an impartial account of Leonardo's achievements as an anatomist and of his status in the history of anatomy. Dr. McMurrich points out that, though Leonardo was greatly influenced by the Arabists, particularly as regards his nomenclature and physiology, he merits the title of great anatomist as well as of great artist by being the inaugurator of a revolution in descriptive anatomy. Although he was guilty of many errors both of omission and of commission, he made many important discoveries, among which may be mentioned those of the frontal and maxillary sinuses, the moderator band of the heart, the bronchial arteries, and arteriosclerosis. He was moreover, distinguished from his medieval predecessors and his contemporaries by greater thoroughness, which is particularly illustrated in his studies of individual bones and muscles, as well as by his investigations of the heart, digestive system, brain, and generative organs. As regards Leonardo's place in the history of anatomy, Dr. McMurrich maintains that though Leonardo's influence on the progress of anatomical knowledge was undoubtedly reduced by the fact that his discoveries were not published, it cannot have been entirely lacking, as his studies must have been known to the leaders of scientific thought, such as Pacioli, the Marliani, and the Cardani, who frequented the Florentine and Milanese courts, as well as to his fellow-artists and his colleagues in the Florentine Guild of Physicians and Apothecaries.

Place-Memory shown by Butterflies.—In 1918 William Beebe described what seemed to be a regular homing movement by a zebra butterfly, *Heliconia*, which nightly returned in groups to the same roosting place, and he interpreted his observations as indicating that these butterflies possessed memory, sociability, and caution. During 1930, as well as in preceding years, F. Morton Jones made definite attempts to check Beebe's observations, in the Royal Palm State Park of Florida, where *Heliconia clarithonia* is usually fairly abundant from mid-January to April (*Natural History*, Nov.-Dec. 1930, p. 635). Six roosting places were discovered, and about these, while daylight was failing, the butterflies collected in numbers, filling the air in swirling flight, making preliminary exploring surveys, and finally settling down for the night. The marking of several individuals showed that for several nights in succession the same butterfly may return to a particular twig, but this detailed accuracy of return was by no means a general rule. Was the homing due to place memory or to scent? A simple experiment settled the question. Branches on which a number

of Heliconias had roosted were removed during the day and placed on another bush within the exploring range The butterflies returned at nightfall, circled about the old bush, apparently observed that something was amiss, continued their exploring flights, and finally settled down upon twigs in the old roosting bush Some, during their explorations, paused upon the transferred twigs, only to leave them again and rejoin the flying group After dark, twenty-seven were found in new positions in the old bush, and only one on the transferred twigs, ten feet away Apparently place memory is the guiding power

Teleost Fishes from the Bahamas—Mr Albert Eide Parr has continued his investigations on fishes from the *Pawnee* Expedition's "Teleostean Shore and Shallow-Water Fishes from the Bahamas and Turk's Island" (*Bulletin of the Bingham Oceanographic Collection* Peabody Museum of Natural History, Yale University Scientific results of the third oceanographic expedition of the *Pawnee*, 1927 July 1930) The present portion includes a very large number of fishes, numbering 150 species in all, in which there is one new genus, eleven new species, and one new sub species, besides many rare and little known forms which previously were insufficiently described The new genus *Amphelikturus* is created for Barbour's *Siphostoma dendriticum* and a new species named *Amphelikturus brachyrhynchus* The latter is a handsome fish with dendritic processes on almost the whole of the body, even on the ocular bulbs The genus is closely related to *Halicythys*, differing, however, by the presence of a caudal fin and of protecting processes for the brood pouch. The two genera occupy an intermediate position between the Syngnathinæ and the Hippocampinæ There are, in this paper, valuable discussions on the affinities of certain species, based on careful measurements and colour notes taken from the living fishes

Toxicity of Nicotine to Insects—Previous investigations on the toxicity of nicotine to insects have involved chiefly a study of the effects of its application as sprays or dips, whereby the alkaloid is presented in molecular and ionic form The actual toxic effect has been generally attributed to the entrance of the gaseous molecules into the tracheal system of the insect C H Richardson and H H Shepard, however, describe some experiments (*Journal of Agricultural Research*, vol 41, p 337) with mosquito larvæ, in which the nicotine was presented in aqueous solution only, and in which a wide range in the relative concentration of ions and dissolved molecules was obtained by varying the pH value With aqueous solutions of nicotine of 0 03M concentration an increased toxicity was shown with an increase in pH value, the maximum effect being obtained with pH 9 7 (the free base) Further, at pH 5 0, concentrations from 0 1M to 0 0001M nicotine were five to seven times more toxic than was the sulphate at the same concentration Since these results show that the free base is more toxic than its salts in the absence of the gaseous phase, the view that the greater toxicity of the alkaloid is due to its greater volatility, hitherto put forward by other workers who obtained a similar result with methods including this form, cannot be accepted The speed of the toxic action was found to be directly related to the concentration of the undissociated molecules, so that toxicity is believed to result largely from the penetration of the wall of the alimentary tract by the alkaloid in this form Nicotine ions are also toxic, but considerably less so than the molecules

Eye Colour in *Gammarus*—The eye colour of the wild *Gammarus chevreuxi* is always black, and no variation from the normal black has ever been observed in the many thousands of this amphipod which have been collected in the native habitat of the species at Plymouth This, however, does not preclude the possibility, as is pointed out by E W. Sexton, A R Clark, and G M Spooner (*Jour Mar Biol Assoc*, 17, No 1, Sept 1930), that mutations may have arisen in the wild stock and have disappeared in the struggle for survival The difficulty these investigators have experienced in establishing mutant stocks in the laboratory indicates that the mutations of the type used for genetical study would have but little chance, under normal conditions in Nature, of survival through the early critical period But once established, the mutants tend to become healthier with each generation, and some are able in time to hold their own with the normal wild black-eyed animals in vigour, length of life, and number of offspring The pigment of the eye begins in normal cases as bright scarlet in the embryo and passes through various darkening stages to jet black by the time of hatching In five stocks, all genetically distinct from one another, there have arisen red-eyed specimens in which the red colour persists after hatching The first was observed in 1912, the second, third, and fourth in 1922, and the new mutant stock, dealt with in the present paper, is descended from one of the wild pairs brought into the laboratory in 1928 for temperature experiments The inheritance of this type of red eye, in which intermediate stages and various colour changes occur, is of a complicated kind, and an interpretation in terms of Mendelian genes would clearly involve several genes and interplay of one kind or another among them The matings with this stock have reached the eighth filial generation and the details thereof are clearly set out

Mineral Production of India—To all who are interested in the geology, mining industry, and economics of India the Quinquennial Review of the mineral production of India is a most useful and instructive publication The period under review is from 1924 to 1928 inclusive (*Rec Geol Surv India*, 64, p 446, 1930) The output of coal has slowly but steadily increased since 1925, though unfortunately there has been an equally steady drop in value India is the largest coal producer among the British dependencies The output of petroleum has not varied much, but owing to the marked rise in world production India's percentage contribution has fallen to 0 7 per cent The 1929 figures reveal a notable increase in value, though the world percentage has further dropped to 0 61 per cent The total of the manganese output has gone up, and though the output has risen still further in 1929 the value has dropped, and the industry is at present in a somewhat depressed condition There has been a steady decline in gold production since the early stages of the War period A general increase in the production of lead, zinc, and silver is recorded The output of tin is also increasing, and a slight set back in 1928 was more than recovered in 1929 The quantity and value of iron ore showed a definite improvement India is the second largest producer of iron in the Empire and yields place only to Great Britain Copper also shows a marked increase, continued in 1929 as a result of the activities of the Indian Copper Corporation The report of the mineral production for 1929 is published in the *Rec Geol Surv India*, 63, pt 3, 1930, and brings the Indian statistics up to-date

Recent and Fossil Foraminifera—In the hope of furnishing evidence for the interpretation of fossil faunas, R D Norton ("Ecologic Relations of some Foraminifera", *Bull Scripps Instit Oceanogr*, 2,

pp 331-388, 1930) has studied the conditions affecting the distribution of some 550 species and varieties of Foraminifera found in the Floridan and West Indian regions, ranging in depth from the beach to 2849 fathoms In water of 0 5 fm, where the annual temperature range is 21°-32° C, the Miliolidæ and Peneroplidæ are generally common or abundant, but at 5-60 fm, where the temperature range is 20°-31° C, there is a marked decrease in the number of species and individuals of those families At 500-2850 fm, with a temperature range of only 2°-8° C, the Globigerinidæ and the Globorotaliidæ are predominant The Rotaliidæ and Anomalinidæ are present at nearly all depths and, as families, do not seem to possess much ecologic value J A Cushman and W W Valentine ("Shallow water Foraminifera from the Channel Islands of Southern California", *Contrib Depart Geol Stanford Univ*, pp 1-31, pls i-x, 1930) give an account of the Foraminifera found in shallow water around the islands of Southern California The fauna is related to that of the west coast of South America, and to some extent to that of the West Indian region W P Woodring ("Upper Eocene Orbitoid Foraminifera from the Western Santa Ynez Range, California", *Trans S Diego Soc Nat Hist*, 6, pp 145 170, pls 13 17, 1930) describes new species of *Discocyclina* and *Actinocyclina* from a soft limestone of the western Santa Ynez range The latter genus is widely distributed in eastern United States, the West Indies, and Central and South America, where it is limited to the Upper Eocene H Yabe and S Hanzawa ("Tertiary Foraminiferous Rocks of Taiwan, Formosa", *Sci Rep Tôhoku Imp Univ, Sendai*, ser 2, Geol, 14, pp 1 46, pls 1 16, 1930) record 38 species of Foraminifera from Oligocene and Miocene deposits of Taiwan They belong principally to the genera *Lepidocyclina*, *Miogypsina*, *Gypsina*, and *Operculina*

Cosmic Radiation—Details of fresh measurements of the cosmic radiation are given by Prof R A Millikan in the issue of the *Physical Review* for Dec 1 These have been made partly at Pasadena and partly at Churchill, on the west side of Hudson's Bay and 730 miles south of the magnetic pole A new high-pressure electroscope has been used which gives greater accuracy than Prof Millikan's earlier instruments, and it has been found that the cosmic rays have the same intensity at these two places to within one per cent., it is concluded that they enter the earth uniformly from all parts of the sky, and that, at the outer limit of the atmosphere, they are composed of ether waves and not of electrons The intensity was found to be independent of the positions of celestial objects, but it showed a diurnal variation, going through a maximum every afternoon and a minimum every morning, even after corrections had been made to bring the readings to a common barometric pressure This is attributed to the fact that the barometer is affected by both the temperature and the weight of the superincumbent air, whilst the response of a closed cosmic ray electroscope depends only upon the mass of air above it As Prof Millikan points out, combined cosmic ray and pressure measurements may thus be of much value in meteorology Prof Millikan considers that the observed cosmic ray effects are all in good agreement with the predictions of the Klein-Nishina absorption formula, thus lending support to his hypothesis that the rays are due to atomic syntheses occurring "in the depths of space"

A Variable Capacitance Cylindrical Condenser—In a paper read to the Institution of Electrical Engineers on Jan 7, E B Moullin describes a cylindrical condenser the capacitance of which can be varied gradually through a wide range One cylinder is totally enclosed by the other and their axes are parallel. The axes are coincident when the capacitance is a minimum By moving the axis of the inner cylinder away from the central position the capacitance increases gradually, being a maximum when their axes are farthest apart With the dimensions chosen, the capacitance is increased by one micro-microfarad (1 $\mu\mu$F) by rotating the pointer through 45°, the total change in the capacitance being 16 $\mu\mu$F The capacitance values engraved on the scale are determined by calculation and not by experimental calibration It is shown by electrostatic principles that the end effect capacitance, at least to a first approximation, is constant as the position of the inner cylinder is varied This was verified experimentally by careful tests It was also found possible to use the condenser as a small variable inductance It was found that the residual inductance of the condenser was the twentieth part of a millihenry A method is shown of combining the tubular inductance and the tubular condenser so as to form a robust and self screening short wave wavemeter of small range Experiments prove that the instrument is capable of measuring a wave length correctly to about 0 07 of 1 per cent This practical device is a good illustration of a useful application of mathematics to physics

Draper's Law—The researches of Draper and of Bunsen and Roscoe showed that the rate of photochemical union of hydrogen and chlorine was proportional to the light intensity In 1921 Baly and Barker found that the rate increased faster than the light intensity, but Mrs Chapman in 1924 was unable to confirm this In the December number of the *Journal of the Chemical Society*, Allmand and Beesley describe experiments which agree with Mrs Chapman's results, and they also suggest a possible explanation of those of Baly and Barker

Heterogeneous Equilibria in the Iron-Oxygen-Hydrogen System—The values of the equilibrium constants in the reactions

$$FeO + H_2 = Fe + H_2O$$
$$\text{and } Fe_3O_4 + H_2 = 3\,FeO + H_2O$$

have been determined at various temperatures by Emmett and Shultz, whose experiments are described in the November number of the *Journal of the American Chemical Society* A discussion of previous experiments is given, and the importance of surface effects is emphasised The results are of importance, since, when taken in conjunction with previous experiments on the iron carbon oxygen system, they lead to values for the water gas equilibrium These are calculated and are shown to be in agreement with the directly determined values of Neumann and Köhler, published in 1928

Anhydrous Stannous Chloride—Anhydrous stannous chloride, $SnCl_2$, may be obtained by passing hydrogen chloride over heated tin A more convenient method is described by Stephen in the December number of the *Journal of the Chemical Society* The crystalline hydrate ($SnCl_2$, $2H_2O$, 1 mol) is treated with acetic anhydride (2 mols) Much heat is evolved and the anhydrous salt separates It is washed with dry ether and can then be kept indefinitely in a desiccator The anhydrous chloride, which crystallises in long needles from acetic acid containing a little acetic anhydride, does not appear to be hydroscopic It is soluble in acetone and amyl alcohol, insoluble in benzene, toluene, xylene, and chloroform It dissolves readily in absolute methyl and ethyl alcohols, but a trace of water causes hydrolysis with the formation of an opalescent precipitate

Sea Fisheries Statistics.*

THE statistical tables for 1928 of the sea fisheries of the north and west of Europe, brought together and edited by Prof D'Arcy Wentworth Thompson, show much that is of interest By a recent resolution of the International Council, "the value and quantity of fish landed in each country is now and henceforth to mean only such fish as is landed by the fishing-fleets of that country, all fish caught by the vessels of any particular country are credited to that country, whether they be landed at home or abroad, and (for instance) trawled fish landed by a German at Aberdeen is treated as part of the German catch and not of the Scotch " This does away with a statistical difficulty which in some countries, notably Great Britain and Germany, was serious

The total values of the fisheries of northern and western Europe (including Portugal) amounted in 1928 to nearly £47,000,000, and the total quantity of fish landed was rather more than 3,300,000 English tons Using the returns of the year 1913 as a normal standard of comparison, the money value of each catch was 46½ per cent above that of 1913, 6 per cent greater than in 1927, and the largest figure since 1924, but it was much less than the total earnings of the fisheries during the inflated prices of the years 1918–1920 These total values and quantities are unaffected by the change of statistical method, but this change affects the returns of some of the individual countries In Great Britain the value of the fisheries has increased to an extent nearly sufficient to compensate for the deduction of value due to foreign landings The total quantity of fish landed in 1928 is the largest on record for most of the countries concerned, as that for 1927 had been in its turn, exceeding the catch of 1913 by about 20 per cent All countries show an increased catch in 1928 except Great Britain and France The average price was the same in 1927, about 20 per cent above the average price in 1913 Of the more important fishes, herring alone in 1928 is at a lower average price (about 7 per cent lower) than in 1913 Trouble in the herring market and difficulties of export trade account for this

In the North Sea fisheries the catch increased steadily until 1913, when it reached its maximum of a million and a quarter tons During the War the landings were reduced to less than half By 1920 the pre-War catch was nearly equalled, but again went down in 1921 and 1922 Since then the catches have increased, and in 1928 amounted to 91 per cent of the 1913 totals The net fishery (to all intents and purposes identical with the herring fishery) is all but equal to that of 1913, the line fishing has increased considerably, but the trawl landings are no more than 85 per cent of those of 1913 The Danish seine came into use later, and only found its place as a separate entry in the tables in 1925 Within the last four years this fishery has not increased, but not diminished to any serious extent, and rather more fish were landed in 1928 from the North Sea by means of the Danish seine than by the line fishery

Herring, haddock, cod, and plaice are the most important fishes in most of the countries concerned, yielding more than half of the whole revenue except in France, Belgium, Poland, and Portugal The tables showing the share contributed by these fishes to the total fishery revenue vary little from year to year The herring fishery in the North Sea is not so great as it was—at least in its relative importance—but is not going back, and for the last three or four years its relative share of the total value has been slowly but steadily rising The fluctuations in the relative shares of the various countries in the North Sea catch are chiefly due to the herring The catch of herring was a good one in 1928 in both the Kattegat and the Skagerrak, and herring constituted very nearly two-thirds of the whole quantity of fish landed from the North Sea Haddock was higher in 1928 than in 1913, both in quantity and value, cod had risen in total value but fallen in quantity, plaice and sole had both improved in relative quantity and value

Very high figures are shown for 'small' plaice from the trawlers, especially in Holland, and these tend to increase, this is also the case for the haddock, the cod increasing much after 1913, but dwindling again in 1928

Part 2 is occupied with tables of general statistics, and there is a list of the common names of the fishes as used in the different countries

* Conseil Permanent International pour l Exploration de la Mer 'Bulletin statistique des pêches maritimes des pays du nord et de l'ouest de l Europe Publié par le bureau du Conseil Vol 18, pour l année 1928 (Copenhagen Andr Fred Høst et fils, 1930)

The Timber of Corsican Pine.

CORSICAN pine (*Pinus Laricio*) is being planted in Britain at the present day on a very considerable scale, especially under the auspices of the Forestry Commission In fact, it is being given preference, owing to the greater rapidity of growth, over the indigenous pine, the volume of Quality I Corsican being 40 per cent greater than for the same quality Scots pine In how far this action will prove justifiable must be left to the future to disclose Those who are paying serious attention to the question will welcome *Bulletin* No 6, "The Timber of Corsican Pine", of the Forest Products Research Laboratory (London H M Stationery Office, 1930 2*s* 6*d* net), which gives the results so far attained in the study made in the laboratory of the timber of Corsican pine grown in Great Britain As the introduction to the bulletin rightly says "The extensive plantations of this species that are being formed throughout Great Britain will in time yield a considerable quantity of timber, and it is important to know what are the characteristics of this timber as grown in this country and hence for what purposes it is suited"

Fortunately, there are in existence plantations of sufficient age to enable timber tests to be carried out, for though it is only during the last fifty years that it has been at all extensively planted, the species was introduced into England about 1759 The timber used for the mechanical tests was obtained from a plantation on Lord Leicester's estate at Holkham and from the New Forest, near Knightswood The value of this species for pit props has also been investigated, the material for the purpose being obtained through the Forestry Commissioners from the Forest of Bere, Leuchars, Fife, and the Forest of Dean The pit props from these two areas were compared with imported props from Scandinavia and the Baltic

For the very interesting and important data which have so far been obtained from the investigations carried out reference must be made to the bulletin The conclusions arrived at are summarised as follows.

The timber is moderately light, very resinous, with a texture somewhat coarser than Scots pine. It can be readily seasoned, either in the open or in the kiln The timber has a tendency to take on a deeper tinge if high temperatures are used, but this does not neces-

-sarily prove detrimental to its use It can be readily air seasoned, but, as the sapwood is liable to blue stain, the logs must be converted as soon as possible after felling, and similarly seasoning should proceed as rapidly as possible after conversion In the case of air-seasoning, open stacking is recommended

*Although the timber has a strength equal to the average pines, except the pitch pines, it is not so strong as Scots pine or home grown Douglas, a point requiring careful consideration It is inclined to be brittle and consequently should not be used in positions where it would have to resist the application of sudden loads or shocks As a mechanical timber it is probably of most use as a post, where its strength in compression parallel to the grain is almost equal to that of the Scots pine Corsican pine takes readily either creosote or water solutions The timber works easily under all tools and takes a finish equal to Scots pine There is, however, a considerable proportion of sapwood and this is more difficult to cut than the heartwood The frequency of knots detracts also from the appearance in finishing any large surface of timber The knots are to a considerable extent due to faulty methods of growth in the past, and this defect should be eliminated in the future It is said that the timber would then be suitable for all classes of finer joinery in which Scots pine is at present used It would also be useful for boxes, packing cases, and crates Owing to the readiness with which it takes creosote, it has a possible future as railway sleepers

As regards pit props, this timber, when carefully graded (the latter point is of first importance), is equal to Scots pine and compares favourably with imported props of the same grade The props must not be left with the bark on for any considerable time

To those interested in the afforestation question and to the future uses to which the timbers of the species now being planted may be put, a study of this bulletin should prove of the greatest interest It also furnishes evidence of the important nature of the work being undertaken by the Forest Products Research Laboratory at Princes Risborough

---

Annual Conference of the Geographical Association

THE annual conference of the Geographical Association was held at the London School of Economics on Dec 31–Jan 3, and was followed by a week end visit to St Albans There could be few more adequate tributes to the vitality of the modern science of geography and the increasing recognition of its importance in all walks of life than the steadily expanding activities of this annual gathering It is estimated that between five hundred and six hundred members took part, and more than a hundred sat down to the annual dinner on Jan 2, whilst the publishers' exhibition was larger than on any previous occasion It is significant of the mutual appreciation of two bodies engaged in spreading knowledge of the earth as the environment of man and the responsibilities of the voter of to-day as a citizen of the world, that the opening gathering of the conference took place in the galleries of the Imperial Institute Here, members and their friends were welcomed by Lieut General Sir William Furse

Mr B B Dickinson, in his presidential address, dealt with the early history of the Association, modestly attempting to disclaim his title of founder His interesting account of the steps by which geographical teaching has been improved and of how the interests of teachers were watched by the young Association was provided with a sequel at the annual dinner by the announcement of a presentation shortly to be made to Miss R M Fleming Under the guidance of Prof H J Fleure as honorary secretary, no one has done more to further the work of the Association—its membership of more than 4000, its library, its lantern-slide collection, and its branch organisations —than Miss Fleming Very appropriately, her recent travels in Russia provided some of the material for a very able account of the geographical regions of the country, a lecture which attracted many more than could be admitted

In the annual report, reference was made to the transfer of the headquarters to Manchester, and to the acceptance by Sir Leslie Mackenzie of the presidency for 1931 Mr J Fairgrieve reported on the work of the Commission on Educational Films, holding that the present day teachers must in any case face the problem of using films for a generation of children already film minded as freely as they would a black board Dr L D Stamp, as the director of the Land Utilisation Survey of Britain, referred to that organisation as having grown naturally out of a committee of the Association It is the primary object of the survey to record on the 6 inch Ordnance Survey maps the uses to which the surface of the country is applied, the uses being grouped under half a dozen simple categories So far as possible, county education authorities are being asked to organise the work, which has the approval, amongst others, of Sir Charles Trevelyan, Sir Henry Richards, the County Councils' Association, and the Forestry Commission It is hoped to publish the results as a series of map sheets on the scale of 1 inch to 1 mile

Amongst other lectures may be mentioned Major Hingston's on the investigation of the life of the 'roof' of the equatorial forests of Guiana, Miss Butcher's description of the methods of the study groups organised by Leplay House (Institute of Sociology) as exemplified by surveys made amongst the Chod villages of Bohemia, and Dr P W Bryan's study of population groupings in Britain Dr Bryan maintains that the human habitations marked on the 1-inch Ordnance Survey maps show a characteristic grouping according to the dominant occupation of the area the grouping for example being different in areas of arable farming, pastoral farming, or mining An important series of original maps, showing on the dot method the principal areas of production of the leading crops of Scotland, was exhibited by Mr H J Wood Amongst the group discussions, that on school journeys, which was combined with an exhibition of photographs and work carried out by pupils taken on such journeys, was of special interest

After the termination of the London meetings, about forty members paid a visit to St Albans, where they were received by Sir John and Lady Russell and members of the St Albans Rotary Club An examination of the site of the Roman city (Verulamium) afforded an opportunity of discussing the geographical factors which helped to determine the site of the city on the now elm lined meadows beyond the Ver, and of the Saxon church of St Michael After a visit to the Herts County Museum, the party was received by the Mayor and Mayoress, and a lecture was given by Mr Woolley on the life of St Albans, based on the manuscripts of Matthew Paris On Sunday, after attending a civic service at the cathedral, the house and grounds of Gorhambury (Bacon's home) were seen under the personal guidance of Lady Verulam, and an address on Bacon and his times, given by Sir Richard Lodge, was greatly enjoyed On Monday, after

seeing the cathedral, the party made a tour, visiting especially the Gade Valley, "one of the most interesting valleys in England for the student of transport" Above Tring, from the chalk scarp, an excellent view of the plain was obtained, the richly cultivated chalk-marl terrace with its row of old villages standing out clearly The tour finished with a visit to Rothamsted Experimental Station under the guidance of Sir John Russell

L Dudley Stamp
E E Evans

University and Educational Intelligence.

Cambridge —The Appointments Committee of the Faculty of Medicine has reappointed Dr A E Barclay, of Christ's College, to be University lecturer in medical radiology and electrology

Dr F G Mann, of Downing College, has been elected to a fellowship at Trinity College Dr Mann, who was formerly assistant to the professor of chemistry, is a University lecturer in chemistry

Glasgow —On Tuesday last, at a ceremony in the Randolph Hall of the University, Sir Frederick Gowland Hopkins, president of the Royal Society, presented, on behalf of the subscribers, to Prof Robert Muir, his portrait by Mr G Fiddes Watt, and to the University a bust by Mr G H Paulin

London —The Court has accepted, on behalf of the University, the generous bequest of £4000, free of legacy duty, from the late Miss Mary Ethel Sim Scharlieb, who died on May 31, 1926 The purpose of the bequest is the founding of a scholarship in memory of Miss Scharlieb's mother, the late Dame Mary Ann Dacomb Scharlieb, to whose life interest the legacy was subject The conditions of award are to be determined by the University

---

The eighteenth series of *Methods and Problems of Medical Education* has been issued by the Rockefeller Foundation, New York, U S A This volume deals particularly with institutes and laboratories of physiology and physiological and bio chemistry, together with some pathological and other special departments, in all parts of the world As in previous series, descriptions of the laboratories are given, with illustrations and plans, and in some instances the staffing and budgets of the departments are appended

The annual report of the University of Leeds to the Worshipful Company of Clothworkers of the City of London on its textile industries and colour chemistry and dyeing departments will be read with additional interest in view of the recent controversies regarding the Dyestuffs Act of 1920 Both departments showed a falling off in the number of day students, and the textile industries department's enrolment of evening students decreased from 110 to 94 They both report, however, a brisk demand for the services of their past students, and the colour chemistry and dyeing department could have placed in suitable positions more students than were ready for employment Great interest was taken in the work of the department by numerous firms, which not only consulted its head when vacancies occurred in their staffs, but also gave a great variety of chemicals, artificial silks, and other textile materials, machinery, etc All students awarded research scholarships in recent years have completed arrangements for their employment in industry some months in advance of leaving the Department Attached to the report is a list of publications by members of the departments

Birthdays and Research Centres.

Jan 25, 1875 —Mr S S Cook, F R S, technical manager of the Parsons Marine Steam Turbine Co

The chief objects of present investigations are the development of high pressure turbine machinery for marine propulsion, and the investigation of thermodynamic and hydrodynamic problems, including cavitation and water hammer erosion.

Jan 26, 1885 —Mr H R Ricardo, F R S, technical director of Ricardo and Co, Ltd, consulting engineers

At present I am occupied chiefly with the design and development of light, high speed, heavy oil engines for all mobile purposes This problem includes an investigation into the factors controlling combustion under the conditions of compression ignition, in relation both to combustion chamber design and to the preparation of suitable fuels

Jan 27, 1856 —Prof Edward B Poulton, F R S, Hope professor of zoology in the University of Oxford

My chief object is to bring together and publish in a series of parts the observations on the bionomics of insects which have appeared scattered through many journals and books during the past forty five years, especially those which deal with protective (cryptic) resemblance, warning (aposematic) characters, and mimicry, both Mullerian (synaposematic) and Batesian (pseudaposematic), also with epigamic characters and their display or manifestation in other ways I hope to be able to include such interesting new observations on these subjects as are likely to be recorded in the near future

Jan 27, 1864 —Prof J W Gregory, F R S, lately professor of geology in the University of Glasgow

I am at present in a transitional stage, for, having recently resigned my chair, I am hoping for leisure to work at several problems which have always specially interested me In the meanwhile, I am trying to finish some arrears of incomplete work, such as a paper on the sequence of the Dalradian rocks of the Southern Highlands of Scotland, and a paper on the australites or obsidian buttons of Australia Later I hope to secure leisure for work on some problems of general geomorphology, including the analogies in tectonic structure of Africa and South America, and complete a study of the geological history of the oceans, of which two sections were dealt with in an address to the Geological Society I have also material collected at various times and still undescribed

Jan 30, 1851 —Dr Henry Ogg Forbes, consulting director of museums to the Corporation of Liverpool

For some time I have been incapacitated from undertaking any new scientific or literary work, owing to the painful results of the collapse of a chair in the British Museum Reading Room Should, however, the surgical operation proposed restore me, as anticipated, to some measure of relief, I look forward hopefully to publishing the ethnographical and geographical observations made in Sokotra (indicated in the preface to "The Natural History of Sokotra and Abd-El-Kuri") and in Peru

Societies and Academies

LONDON

Royal Society, Jan 15 —**Lord Rayleigh** Iridescent colours of birds and insects The reflection spectra of various brilliantly coloured insects have been examined in the ultra-violet *Morpho* butterflies and *Urania* moths show ultra violet maxima in general agreement with the theory of interference Iridescent beetles showing a deep red colour at normal incidence may be made to pass through all the colours of the spectrum to violet, provided that arrangements are made to annul refraction at the air chitin surface Some of the golden beetles show transmission spectra of bands which vary continuously in position with the part of the specimen examined Moist chlorine gas does not destroy the colours of *Morpho* or of *Urania*, though the black background is bleached nor does chlorine decolorise the metallic beetles The colours of all kinds of feathers, however, are rapidly discharged Peacock feathers undergo a progressive change of colour in ultra violet light or long continued sunlight Generally speaking, the colours become more refrangible Other feathers, even when blue, are slowly decolorised without change of refrangibility *Morpho* butterflies and *Urania* also lose colour without change of refrangibility Fading under light or chlorine in these cases would seem to favour the idea of a pigment, but it is attributed to the breaking down of an interference structure —**O W Richardson** and **L G Grimmett** The emission of electrons under the influence of chemical action at lower gas pressures A method is described by which partial pressures of phosgene can be controlled and their changes measured down to 10^{-5} mm mercury The electron emission from NaK in this gas has been measured down to directly measured pressures of 10^{-5} and to extrapolated pressures of 5×10^{-7} mm under various conditions In contrast to the results at pressures above 10^{-3} mm, the emission is now found to be a function of the gas pressure as Richardson originally supposed The experimentally determined velocity distribution function among the electrons approaches a limit as the pressure is reduced —**A J Allmand** and **A Puttick** The sorption of carbon tetrachloride at low pressures by activated charcoals (Part 4) Work has been done on the effect of high temperature evaluation on the nature of vapour isothermals on charcoal It has been found that the carbon tetrachloride isothermal on at least one charcoal has a discontinuous structure If a sufficiently high charging pressure of sorbate is used, a reversible isothermal can be obtained —**D Marshall** and **Sir Thomas Stanton** The eddy system in the wake of flat circular plates in three dimensional flow The paper describes experiments on the flow of water in steady motion past flat circular plates normal to the direction of motion The nature of the flow is rendered visible by colouring the streams, and simultaneous photographs on two planes at right angles of the motion in the wake of the plates were obtained At speeds lying between a well defined upper limit and a lower limit well above that corresponding with a state of flow in which the inertia terms are negligible, a permanent vortex ring was observed at the back of the plate When the speed exceeded the upper limit the substance of the ring was discharged downstream in a series of vortices of definite pitch and periodicity —**J Chadwick**, **J E R Constable**, and **E C Pollard** Artificial disintegration by α particles The protons emitted by certain elements when bombarded by α particles have been examined by an electrical method Except in the cases of fluorine and sodium, the disintegration protons consisted of different groups The origin of these groups is explained on the assumption that the protons and α particles contained in a nucleus are in definite energy levels The mass defects of certain nuclei formed in the disintegration processes are deduced

Physical Society, Dec 5 —**C A Kloss** Relations between the fundamental physical constants The numerical values of the fundamental physical constants have been expressed in forms all of which involve, exactly or approximately, the quantity 10^{-13}, and some possible inferences from these values have been suggested —**W A Wood** The influence of the crystal orientation of the cathode on that of an electro deposited layer This is studied by X ray methods for copper and nickel, respectively deposited on rolled copper The conditions of cathode surface and current density which accompany an oriented deposit are determined The orientation of the copper deposit for small currents is the same as that of the cathode The nickel, at low current densities assumes a distinct orientation As the current is increased there is a region of no orientation, followed at still higher currents by one exhibiting the same orientation as that of the cathode surface below —**B K Johnson** Sources of illumination for ultra violet microscopy Experiences encountered in an attempt to find means for reducing the exposures hitherto necessary in ultra violet microscopy are described Amongst the subjects dealt with are quantitative measurements of the relative intrinsic brightness of spectrum lines given by various sources of radiation methods of producing a monochromatic source suitable for this work, the steadiness of the illuminant the effect on the definition of the image when a triple spectrum line is used as a source, the study of electrical conditions for the production of increased brightness of the spark, such as the effects of change in frequency, secondary potential, capacity, and energy input, and the production of a compact and inexpensive electrical unit for use with the ultra violet microscope

PARIS

Academy of Sciences, Dec 8 —**P Villard** The titration of phosphoric acid A study of the reaction of phosphoric acid with solutions of caustic soda, lime, and baryta in the presence of various indicators —Emile Jouguet was elected a member of the Section of Mechanics in succession to the late M Sebert Sir Arnold Theiler was elected *Correspondant* for the Section of Rural Economy in succession to the late Paul Wagner —**G Pfeiffer** The generalisation of the method of Jacobi Mayer —**Georges Giraud** Extension of the results concerning certain problems of data at the frontier —**J A Lappo-Danilevski** Meromorph functions of matrices —**Ridder** Some theorems on primitive functions —**E Gugino** The determination of the forces of reaction in the movement of a material system —**Michel Vacher** The modifications in the fine structure of a spectral line brought about by molecular diffusion Study as a function of the angle of diffusion —**Jean Cabannes** The fine structure of a spectral line after molecular diffusion —**Charles Dufraisse** and **Raymond Horclois** The catalysis of autoxidation the antoxygen or pro oxygen actions of iron and its compounds The catalytic activity of iron varies, both in intensity and sign, with the nature of the salt employed, and also with the nature of the autoxidisable materials with which it is in contact —**André Courty** Study of the casting of light aluminium alloys The influence of chemical composition —**L Lematte**, **G Boinot**, **E Kahane**, and **Mme M Kahane** The phosphotungstates and silico-

tungstates of some quaternary bases Analytical applications Choline and several substitution derivatives of choline form precipitates with phosphotungstic acid and with silicotungstic acid These precipitates are sufficiently constant in composition to be used in analysis —**E Carrière and Juillard** The action of sodium thiosulphate upon potassium iodate in faintly acid solution —**Georges Laude** The synthesis of cyanic acid and of urea by the ammoniacal oxidation of carbon Carbon was prepared from camphor soot purified by extraction with benzene and ether, and finally raised to a dull red heat in a vacuum Acetylene carbon was also used The oxidation was effected by copper powder and potassium permanganate in the presence of concentrated ammonia The cyanic acid produced was estimated as dixanthylurea 100 grams of camphor carbon gave 11 per cent and acetylene carbon 6 per cent of cyanic acid —**Conrad Kilian** An element of decision for the controversy concerning the Plio Pleistocene Saharan sea Since the work of Pomel and of Flamand, the hypothesis of Plio Pleistocene marine penetration of the Sahara has been regarded as completely disproved The observations of the author now described reopen the question the marine hypothesis is still worthy of attention —**M Thoral** New observations on the age of the limestones of the Monts de Lacaune —**E Bruet** Observations on the continental alteration of certain sediments —**J Thoulet** The water cycle liquid columns and cones of gyration —**J P Rothé** The geological interpretation of magnetic measurements in the Paris basin —**Pierre Chouard** The regeneration of small bulbs on the green leaves of certain Liliaceæ The mutilation of the bulb has been used as a means of determining a more active production of buds and small bulbs, but this destroys the mother bulb The author describes a method of producing the small bulbs on the green limbs of the leaves without destroying the mother plant —**Charles Pontillon** The variations of the fatty acids of *Sterigmatocystis nigra* as a function of the mineral composition of the culture fluid **M Bridel and C Charaux** The preparation and properties of the franguloside (frangulino) of commercial alder buckthorn bark A method is described for extracting franguloside from the bark by which the yield is much increased (25 grams per kilogram instead of 1 gram) **R Fosse, A Brunel, P de Graeve, P E Thomas, and J Sarazin** The presence of allantoin, with or without allantoic acid, allantoinase, and uricase, in numerous plants used for food —**W Kopaczewski** The reduction of the capillary buffer action of cancerous serum —**A Bakke, Mlle V Aschehoug, and Chr Zbinden** A new factor of nutrition **Ph Joyet-Lavergne** The notion of somatic sexualisation —**Georges Blanc and J Caminopetros** The transmission of Mediterranean kala azar by a tick *Rhipicephalus sanguineus* —**Joseph Thomas** Injections of cancerous autolysates in the treatment of cancer Clinical observations of cases submitted to injections under the treatment described in an earlier paper The author regards his results as proving that a cancerous tumour is the local expression of a general disease —**F Vlès and A de Coulon** Researches relating to the effects of certain amino acids on the isoelectric points of human serum

ROME

Royal National Academy of the Lincei, June 15 —**U Cisotti** Isotropic quadruple tensors —**G Bruni and G Natta** Crystalline structure of benzene and its relations to that of thiophen (2) The results of X ray examination of solid benzene at $-170°$ by the powder method show that the unit cell is of bipyramidal rhombic form of sides $a = 7\ 34$, $b = 9\ 52$, and $c = 6\ 74$ A, corresponding with the axial ratio $a\ b\ c = 0\ 771\ 1\ 0\ 708$, which differs but little from that determined by Gordon Cox at $-22°$, the density is calculated to be 1 099 No true isomorphism exists between benzene and thiophen, but analogies are evident between the dimensions of the unit cells of the rhombic benzene and the tetragonal thiophen, which have volumes of 471×10^{-24} c c and 498×10^{-24} c c respectively The radiations of long wave length furnished by a metallic calcium anti cathode proved of advantage in the measurements —**G De Lorenzo** The geological cause of the disappearance of the ancient city of Paestum It is now generally thought that the ancient Greek city of Poseidonia, which later became the Paistum of the Lucanians and the Paestum of the Romans, owed its disappearance, not to barbaric invasions and incursions of Saracens, but to conquest by malaria Study of the variations of the sea level observed during historical times along the Tyrrhenian coast of southern Italy indicates that, in the sixth century B C, the surface of the travertine deposit on which this city stood was at least 25 metres above sea level, whereas it is now buried under a deep layer of material of river and marshy origin, cemented by infiltrations of calcareous tufa —**L Petri** An extensive infection of *Pythium* on grain plants —**D Montesano** The normal descendences of geometrical Cremonian groups —**Fausta Audisio** Calculation of π by Leibniz's series —**C Popovici** Remarks on integro functional equations —**Enrico Volterra** The influence of several rigid nuclei immersed in an elastic medium —**B Finzi** The deformation tensor of a film —**M Pierucci** The orbit of the trans Neptunian planet The author's rule, that the distances of the planets—taken in the two groups of internal and external planets—from the sun increase in whole numbers, gives a lower mean error than any other known rule Better agreement with this rule is obtained when it is applied to the geometrical mean of the two semi axes of the orbit, which is termed the 'equivalent radius' If this magnitude for Lowell's planet is taken as the mean of the values given by Banachiewicz and Crommelin, the value of the unit of measurement which renders minimum the sum of the squares of the errors is the same for the four old external planets as when Lowell's planet is included, the mean error of the rule being thus sensibly lowered by the discovery of the new planet —**B Gulotta** The rigorous development, in series of spheric functions, of the external potential and the surface gravity of a spheroidal (not of rotation) planet —**G Bernardini** Characteristic velocities of the electrons diffused by metallic surfaces —**G Racah** Quantistic electrodynamics **G R Levi and D Ghiron** Reduction cells of alkali chlorites Values are given for the reduction potentials at 20° of chlorites with certain reagents in practically neutral solution, neutrality being maintained, when necessary, by means of buffer solutions of sodium borate and magnesium sulphate, and bright platinum electrodes being used —**A Ostrogovich and V Galea** Investigations on γ-triazines Synthesis of arylamino thioltriazines Descriptions are given of five new arylaminothioltriazines, prepared by the condensation of cyanoguanidine with the corresponding arylthio acids —**A Migliavacca** Regeneration of the central nervous system before and after birth

MELBOURNE

Royal Society of Victoria, Nov 13 —**Jean Heyward** Flowering periods of Victorian plants A graphical record was made of the flowering periods of all Victorian genera of plants From these graphs were constructed tables to test a theory put forward by

Illichevsky He considers that plants flower in the order of their phylogenetic evolution the most highly developed plants, being more complex, require for their development a longer time and a greater quantity of warmth than simpler ones, and hence they will flower later in the summer This was not found to be the case with the Victorian flora —**Cedric Deane** Australian Hydrophilidæ In this paper are described nine new species of *Ochthebius*—*O clarki*, *O angustipennis*, *O tenebricosus*, *O longipes*, *O obcordatus*, *O clypeatus*, *O pallidipennis*, *O leai*, and *O fischeri*, also one new *Hydræna*, *H williamsensis* These belong to the section in which the members, though living in the water, do not swim but cling to sticks, stones, and reeds Being winged, it is presumed that they fly by night like their relatives of the swimming section The total number of Australian Ochthebii is now thirteen, and the Hydrænæ six —**Charles Oke** On some Australian Curculionidæ Four new genera are described—*Mandalotina*, *Daylesfordia*, *Dixoncis*, and *Nyella* Also twenty four new species Three new species are referred to the New Zealand genus *Phrynixus*, not previously known in Australia

SYDNEY

Royal Society of New South Wales, Nov 5 —**George Smith** Notes on the mineralogy of the silver lead zinc deposits of New South Wales, with special reference to the Barrier Ranges Silver Field This paper describes the occurrence of the ores and associated minerals, especially at Broken Hill, and particularly the manner in which the ore bodies have been affected by descending solutions, their destructive action on the original minerals contained in the lodes and the production of new mineral combinations The relation of the minerals to the lode gangue is discussed at some length as well as the nature and causes of the secondary enrichment, which was such an important feature of the oxidised zone in the Broken Hill mines

Diary of Societies

FRIDAY, JANUARY 23

ROYAL SOCIETY OF MEDICINE (Disease in Children Section), at 5
ROYAL COLLEGE OF SURGEONS OF ENGLAND, at 5.—Prof. J. W. Tudor Thomas: Successful Grafting of the Cornea in Rabbits.
INSTITUTION OF MECHANICAL ENGINEERS, at 6.—H. N. Gresley: High Pressure Locomotives.
INSTITUTION OF ELECTRICAL ENGINEERS (London Students' Section), at 6.15.—Short Papers on Various Aspects of Lighting.
SOCIETY OF CHEMICAL INDUSTRY (Chemical Engineering Group) (at Friary Hotel, Derby), at 6.30.—J. C. Farrant: Modern Grinding.
INSTITUTE OF FUEL (at Institution of Civil Engineers), at 6.30.—Dr. K. Rummel: The Calculation of the Thermal Characteristics of Regenerators (Melchett Lecture).
INSTITUTION OF STRUCTURAL ENGINEERS (at Chamber of Commerce, Birmingham), at 6.30.—H. M. Hale: Reinforced Construction at Bournemouth Gas Works.
SOCIETY OF CHEMICAL INDUSTRY (South Wales Section) (jointly with Institute of Chemistry and University College of Swansea Chemical Society) (at Thomas's Cafe, Swansea), at 7.—Dr. R. Lessing: Recent Improvements in Coal Cleaning.
INSTITUTION OF STRUCTURAL ENGINEERS (at College of Technology, Manchester), at 7.—A. E. Pierce: Structural Engineering in Modern Gas Works.
WEST OF SCOTLAND IRON AND STEEL INSTITUTE (at Royal Technical College, Glasgow), at 7.15.—J. R. Dickie: The Coking Industry and its Development in Relation to the Manufacture of Iron and Steel.
JUNIOR INSTITUTION OF ENGINEERS (Informal Meeting), at 7.30.—E. W. Thompson: The Progress and Development of Steam Generators.
INSTITUTION OF STRUCTURAL ENGINEERS (at Merchant Venturers' Technical College, Bristol), at 7.30.—M. Morgan: Fatigue of Metals.
ROYAL SOCIETY OF MEDICINE (Epidemiology and State Medicine Section), at 8.—Prof. E. L. Collis: Recent Views on Pneumokoniosis.
ROYAL INSTITUTION OF GREAT BRITAIN, at 9.—Sir William Bragg: The Scattering of Light.

SATURDAY, JANUARY 24

ROYAL INSTITUTION OF GREAT BRITAIN, at 3.—Dr. E. Cammaerts: Flemish Art (1): The Van Eycks.

MONDAY, JANUARY 26

INSTITUTE OF ACTUARIES, at 5.—W. Palin Elderton: Valuations in Modern Conditions.
ROYAL COLLEGE OF SURGEONS OF ENGLAND, at 5.—Prof. D. H. Patey: The Pathological Basis for the Treatment of Varicose Veins by Injections and its Bearing on the Problems of Thrombosis.
INSTITUTION OF MECHANICAL ENGINEERS (Graduates' Section), at 6.45.—R. Walles: Windmills and Millwrighting.
INSTITUTION OF ELECTRICAL ENGINEERS (Informal Meeting), at 7.—I. Murphy and others: Discussion on Reliable Fractional Horse-power Motors for Commercial Purposes.
INSTITUTION OF ELECTRICAL ENGINEERS (North Eastern Centre) (at Armstrong College, Newcastle-upon-Tyne), at 7.—B. Leggett: The Medical and Surgical Applications of Electricity.
ROYAL SOCIETY OF ARTS, at 8.—Dr. L. C. Martin: Some Modern Developments in Microscopy (Cantor Lectures) (1).
ROYAL SOCIETY OF MEDICINE (Odontology Section), at 8.—Dr. A. A. Osman: The Importance of Sugar in the Diet of the School Child.
ROYAL GEOGRAPHICAL SOCIETY, at 8.30.—L. S. B. Leakey: The East African Lakes.

TUESDAY, JANUARY 27

ROYAL SOCIETY OF ARTS (Dominions and Colonies Meeting), at 4.30.—G. E. W. Humphery: Air Communications in Africa.
ROYAL SOCIETY OF MEDICINE (Medicine Section), at 5.—Dr. J. C. Bramwell: The Prognosis and Treatment of Heart Disease complicating Pregnancy.
ROYAL INSTITUTION OF GREAT BRITAIN, at 5.15.—Dr. J. W. T. Walsh: The Art of Illumination (2).
EUGENICS SOCIETY (at Linnean Society), at 5.30.
INSTITUTION OF CIVIL ENGINEERS, at 6.—F. R. Freeman: The Strength of Arc-welded Joints.
INSTITUTION OF ELECTRICAL ENGINEERS (North Midland Centre) (at Hotel Metropole, Leeds), at 7.—C. S. T. Paul and others: Informal Discussion on The Oil-immersed Circuit Breaker.
INSTITUTION OF ELECTRICAL ENGINEERS (North Western Centre) (at College of Technology, Manchester), at 7.—S. G. Brown: Loud-speakers since their Conception with Gramophone Pick-ups and Wireless Recording Apparatus.
ROYAL PHOTOGRAPHIC SOCIETY, at 7.—C. D. Hallam and R. S. Cox: Etching Three-colour Half-tone by means of a Colour Chart.—H. M. Cartwright, A. Haigh, and E. L. Turner: Improvements in Photo-lithography.—Dr. T. Slater Price: Secondary Reactions in Latent Image Formation: Influence of Free Alkali Halide.
QUEKETT MICROSCOPICAL CLUB (at Medical Society of London), at 7.30.—Gossip Meeting.
SHEFFIELD METALLURGICAL ASSOCIATION (at 198 West Street, Sheffield), at 7.30.—F. W. Rowe: The Selection of Suitable Steels for Gears.

WEDNESDAY, JANUARY 28

BRITISH ASTRONOMICAL ASSOCIATION (at Sion College), at 5.
ROYAL COLLEGE OF SURGEONS OF ENGLAND, at 5.—Prof. J. Paterson Ross: The Treatment of Cerebral Tumours with Radium; with an Account of Experiments made to study the Effects of Radium upon Cerebral Tissue.
GEOLOGICAL SOCIETY OF LONDON, at 5.30.
NORTH-EAST COAST INSTITUTION OF ENGINEERS AND SHIPBUILDERS (Graduate Section: Joint Meeting) (at Mining Institute, Newcastle-on-Tyne), at 7.15.—B. Reed: Diesel Electric Vehicles for Railway Service.
ROYAL SOCIETY OF ARTS, at 8.30.—Very Rev. Dean Baillie: The Restoration of St. George's Chapel, Windsor Castle.
INSTITUTION OF ELECTRICAL ENGINEERS (South Midland Centre) (at Central Technical College, Birmingham).—Prof. W. Cramp: The Birth of Electrical Engineering (Faraday Lecture).
INSTITUTION OF CHEMICAL ENGINEERS (Graduates and Students Section).—M. L. Nathan: High Temperature Heat Insulation.

THURSDAY, JANUARY 29

DIESEL ENGINE USERS ASSOCIATION (at Abbey House, Westminster), at 3.—Report of Committee on Heavy Oil Engine Working Costs, 1928–29.
ROYAL SOCIETY, at 4.30.—W. Fernando: (a) The Origin of the Mesoderm in the Gastropod *Viviparus* (= *Paludina*), (b) The Origin and Development of the Pericardium and Kidneys in *Ostrea*.—L. A. Harvey: Studies on Echinoderm Oogenesis.—I. *Antedon bifida* (Pennant). II. *Asterias rubens* (Linn.).—J. Young: The Pupillary Mechanism of the Teleostean Fish *Uranoscopus scaber*.
ROYAL INSTITUTION OF GREAT BRITAIN, at 5.15.—Prof. H. Dingle: The Nature and Scope of Physical Science (2).
ROYAL SOCIETY OF MEDICINE (Neurology Section), at 5.30.—Sir Charles Sherrington: Quantitative Management of Contraction for Lowest-level Co-ordination (Hughlings Jackson Lecture).
ROYAL AERONAUTICAL SOCIETY (at Royal Society of Arts), at 6.30.—A. Lippisch: Development and Construction of Sailplanes and Gliders.
ROYAL AERONAUTICAL SOCIETY (Yeovil Branch) (at Yeovil).—R. Waddell: Machining and Working of Stainless Steel.
SOCIETY OF DYERS AND COLOURISTS (West Riding Section).—Dr. S. C. Barker: The Physical Relationships of the Dimensional Characteristics of the Wool Fibre and their Importance in Manufacturing Practice.

FRIDAY, JANUARY 30

ROYAL COLLEGE OF SURGEONS OF ENGLAND, at 5.—Dr. D. Hunter: Changes in the Bones in Hyperparathyroidism and Hyperthyroidism.
INSTITUTION OF ELECTRICAL ENGINEERS (West Wales (Swansea) Sub-Centre) (at Corporation Electricity Showrooms, Swansea), at 6.—J. Urmston: The Electrical High Pressure Testing of Cables and the Localisation of Faults.
NORTH EAST COAST INSTITUTION OF ENGINEERS AND SHIPBUILDERS (at Mining Institute, Newcastle-upon-Tyne), at 6.—C. F. Christensen: The Whaling Factory Ship *Vikingen*, with Some Notes on Whaling.
JUNIOR INSTITUTION OF ENGINEERS (Informal Meeting), at 7.30.—W. Fish: Modern Methods of Production of Small Machined Work.
ROYAL INSTITUTION OF GREAT BRITAIN, at 9.—Prof. G. M. Trevelyan: The First Defence of Gibraltar by the English, Oct. 1704–April 1705.
ROYAL AERONAUTICAL SOCIETY (Hull and Leeds Branch).—Col. the Master of Sempill: Gliding and Soaring.
SOCIETY OF DYERS AND COLOURISTS (Scottish Section).—D. K. Colledge: Dyeing for the Scottish Tweed Trade.

SATURDAY, JANUARY 31

MATHEMATICAL ASSOCIATION (at Bedford College for Women), at 3.—Annual Meeting.
ROYAL INSTITUTION OF GREAT BRITAIN, at 3.—Dr. E. Cammaerts: Flemish Art (2): Breughel.

PUBLIC LECTURES

SATURDAY, JANUARY 24

HORNIMAN MUSEUM (Forest Hill), at 3.30.—M. A. Phillips: Birds, Past and Present.

MONDAY, JANUARY 26

LONDON SCHOOL OF HYGIENE AND TROPICAL MEDICINE (Public Health Division), at 5.—J. C. Dawes: Public Cleansing: The Composition and Storage of House and Trade Refuse.
KING'S COLLEGE, LONDON, at 5.30.—Prof. J. Barcroft: The Constancy of the Internal Environment: its Evolution and Purpose. (Succeeding Lectures on Feb. 2 and 9.)

TUESDAY, JANUARY 27

LONDON SCHOOL OF ECONOMICS, at 5.—Dr. F. A. Hayek: Prices and Production. (Succeeding Lectures on Jan. 28, 29, and 30.)
IMPERIAL COLLEGE OF SCIENCE AND TECHNOLOGY, at 5.30.—Prof. P. P. Ewald: The Theory of Interference of X-Rays as a Domain of General Crystal Optics. (Succeeding Lectures on Jan. 29 and 30.)

WEDNESDAY, JANUARY 28

LONDON SCHOOL OF HYGIENE AND TROPICAL MEDICINE (Public Health Division), at 5.—J. C. Dawes: Public Cleansing: The Collection of House and Trade Refuse.
KING'S COLLEGE, LONDON, at 5.30.—Prof. A. Pastor: The Great Age of Discovery (2): The Renaissance in Spain and Portugal.
BELFAST MUSEUM AND ART GALLERY, at 8.—C. E. White: Josiah Wedgwood and what the World owes to him.

THURSDAY, JANUARY 29

BEDFORD COLLEGE, at 5.15.—Sir Philip Hartog: Problems of Modern India (1): Education.

SATURDAY, JANUARY 31

HORNIMAN MUSEUM (Forest Hill), at 3.30.—Miss M. A. Murray: Most Ancient Egypt.

SATURDAY, JANUARY 31, 1931

The Worth of Education

THE presidential address delivered on Dec 31 last by Sir Richard Gregory at the nineteenth annual Conference of Educational Associations was entitled "The Worth of Science" Proverbial philosophy warns us of the difficulty—even the impossibility—of getting a quart into a pint pot, otherwise the president might have been able to include a few remarks on the kindred subject, "The Worth of Education" This subject is controversial, especially if discussed in relation to the Education Bill now before Parliament for raising the age for compulsory education to fifteen, and Sir Richard Gregory may have preferred the primrose path of peace and order, or he may have foreseen, warned again by proverbial philosophy, that others, including the present writer, would rush in where angels fear to tread

From this point of view the intervention of Sir Ernest Benn on the following day, addressing the Independent Schools' Association, was *ben trovato* As a business man, he has for some time sounded a booming note like Big Ben into our economic darkness May it continue until the dawn of a new economic day! Why, he asked, did it cost £4 a year before the War to give a child elementary education and £13 to day? In his opinion, there was no public demand for the School Attendance Bill It was a "Bill to educate the child to put the father out of work" The officials of the Board of Education, he supposed, exercised their wits by settling questions which arose among themselves There may be some truth in this, for those who wish to study the question of "The Worth of Education" in the dry light of science must be impressed by the lack of evidence on the subject The student of our elementary education in Victorian times reads and digests Matthew Arnold's "Reports on Elementary Schools, 1852–1882", written, as his editor says, in a simple and telling style with so much knowledge of our own and foreign systems, with so sweet a reasonableness, and with so high authority as an expert But he will look in vain for corresponding official reports to-day

We are all educationists nowadays As Charles Hargrove says, teaching is the most difficult job in the world, but "every parent, teacher, elder brother or sister, trained or untrained, themselves ill taught, impatient, dogmatic, stupid, ignorant, and unsympathetic—all must try, for good or ill" There is certainly a need for guidance and we

should be grateful if the officials of the Board would suspend for the time being their discussion of the questions which arise among themselves in order to give the public trustworthy information about the condition of the schools of England. For, failing such evidence, the public may draw conclusions, possibly wrong ones, from unofficial publications, such as Ethel Mannin's "Confessions and Impressions", a book written by an original author who in happier circumstances might have become President of the Board of Education.

Ethel Mannin and Sir Charles Trevelyan, the President of the Board of Education, have this in common—that neither profited much from school education, though we are not disposed to accept *au pied de la lettre* Sir Charles's denunciation of his old school, Harrow, with its distinguished roll of old boys. Ethel Mannin tells us that during the War she was a pupil at a public elementary school and was told to write an essay on patriotism, a suitable subject. Having heard her father quote Dr. Johnson's dictum, "Patriotism is the last refuge of the scoundrel", she naturally worked it into her essay. For this piece of flagrant subversiveness she "was called up before the head mistress, lectured on the wickedness and stupidity of my attitude, and caused to kneel for a whole morning in the school hall, a punishment popular in the school". Her spirit was not broken. She failed, however, to obtain a secondary school scholarship, collapsing miserably in the viva voce examination! The examiners thought her stupid, but as she observes: "I knew I was not stupid, but only that I had not their kind of non-stupidness". Wise child!

'Expert' is no doubt a much-abused word. Mr. Henry Ford tells us that so soon as a man calls himself an expert, he bundles him out of his works. Ethel Mannin would not claim the proud title of educational expert, but her evidence seems to be very much *ad rem*, pointing as it does to the need for improving our existing elementary education before extending its scope. The most remarkable thing about the discussion of the present Education Bill is that the opinions expressed on its fundamental principles have been, with few exceptions, unfavourable. The Bishop of Gloucester stresses this point in his letter to the *Times* of Jan. 10. "I do not suppose", he writes, "that any educational reform of the magnitude implied by the proposed Hadow schools has ever been introduced with less authority behind it. It has really nothing to support it except a Departmental Committee and a good Press", and later, in the same letter: "It is obvious that the proposal to raise the age of compulsory attendance at schools meets with only a limited approval".

In a short article it is not possible to summarise the views which have been expressed on this question, but readers of NATURE will respect the opinion of Sir William Pope, as given in his Norman Lockyer lecture to the British Science Guild. "There is little to indicate", he said, "that a rationalisation of our educational methods is in progress. Those who have to deal much with the young, realise that many, from all classes of society, are so poorly endowed mentally that all but the rudiments of education are wasted on them. Others, again drawn from every stratum of society, are intellectually so gifted that their education may be profitably extended until well into the twenties." No one will suspect this distinguished chemist of a desire to create 'wage slaves'.

Manual work is sometimes the best method of developing human personality. "I don't like work—no man does", says one of Conrad's characters, "but I like what is in work—the chance to find oneself—your own reality—for yourself, not for others—what no other man ever knew." Regimentation, however distasteful to the English people, is necessary to secure that all children learn to read and write and to do sums, though, as regards the last accomplishment, many of the wise and eminent pass through life by using their fingers, Nature's abacus. But the shades of the prison house should begin to lighten before the growing boy as soon as he has acquired these rudiments of knowledge. Part-time education, Mr. Fisher's golden calf, before which the whole educational world prostrated itself a few years ago, is now cast down—unfortunately, we think, particularly as regards works' schools.

What is most to be regretted, however, is the lack of common sense shown in the discussion of these vital questions. Sir Ernest Benn (*loc. cit.*) said that in 1830 very little common sense in regard to education was to be found. We will show our possession of this rare commodity by bringing this article to a close before it becomes discursive—and how better than by reproducing Sir Richard Gregory's quotation in his address on "The Worth of Science" from Descartes, who said that he studied science "to learn how to distinguish truth from falsehood, in order to be clear about my actions and to walk surefootedly in this life".

T. Ll. H.

Geometry of Four Dimensions.

Geometry of Four Dimensions By Prof A R Forsyth Vol 1 Pp. xxix + 468 Vol 2 Pp xi + 520 (Cambridge At the University Press, 1930) 75s net

THIS work, which is primarily a formal treatise on the differential geometry of curves, surfaces, and threefold regions in ordinary homaloidal space of four dimensions, follows fairly closely on the lines of the author's very well known treatise on differential geometry in a three-dimensional space Prof Forsyth naturally prefers, however, in a treatise of this kind, not to assume, on the part of the reader, any previous knowledge of the elementary metrical properties of lines, planes, and planar threefolds in four dimensions, and he devotes the first half of his first volume, therefore, to a very systematic investigation of such properties, partly as a foundation to the subsequent theory, and partly for their own sake This section of his work includes, therefore, a consideration of such concepts as the four direction cosines of a line and the six orientation co ordinates of a plane, leading up to a very complete set of formulæ for the inclination and other properties of lines, planes, and threefolds in four dimensions, and though some readers will probably claim that part of this work could have been simplified by making use of the projective aspect of metrical four space, and in particular by introducing the concepts of solid at infinity and absolute quadric, yet no one will deny that the author's treatment is very clear and adequate as it stands He concludes this more elementary work by a chapter on what he calls *globular* representation of directions, analogous to spherical representation in ordinary space, and uses this in the analysis of general finite or infinitesimal displacements of the orthogonal frame of reference

The remainder of the first volume is taken up with the foundations of the differential theory of curves and surfaces in four dimensions, the analysis involved being very analogous to that in Prof Forsyth's former treatise referred to already He proceeds in particular to establish the properties of a curve at a point of itself, namely, the natural orthogonal frame of reference at the point, the curvature, torsion, and tilt of the curve, and the centres and radii of circular, spherical, and globular curvature He investigates also the curves, analogous to the helix in ordinary space, which have constant curvature, torsion, and tilt, and also those for which the ratios only of these are constant In Chapter ix he considers the dual aspect of a curve as the edge of regression of a developable generated by the intersection of consecutive solids of a simply infinite family, and further on, he interprets the various developables associated with a curve , and finally, in Chapter xi he finishes off his work on curves by outlining briefly the general theory of a curve in any number of dimensions

The chapters on surfaces which occupy the remainder of vol 1 provide a most fascinating investigation, presented with delightful clarity and skill of exposition It appears that a surface in four dimensions is a much more interesting construct in some ways than one in three dimensions It has, for example, at any point O of itself, a normal or orthogonal plane N instead of a unique normal line as in three dimensions, and it appears on one hand that the intersections with N of the normal planes at points consecutive to O lie on a conic in N called by Kommerell the *characteristic conic* of the point O, while on the other hand, the centres of circular curvature at O of geodesics through O lie on a lemniscate in N which is in fact the pedal of the conic in regard to O Not only so, however, for it appears in addition that there are four principal radii of circular curvature of geodesics through O, and these turn out very nicely to be the four normals from O to the characteristic conic, while the feet of the normals, which incidentally are points of contact of the conic and the lemniscate, are the centres of curvature on the four radii in question Prof Forsyth has certainly succeeded in giving a fine account of this fascinating theory

In the second volume the author begins by laying the foundations of the theory of curved three dimensional regions in space of four dimensions He defines such a region by giving expressions for the co ordinates in terms of three parameters, and after obtaining the fundamental quadratic differential form for an arc element on the region, he places on record all the necessary relations between the various associated magnitudes, including expressions for the parameter derivatives of the coefficients of the fundamental quadratic form in terms of Christoffel index symbols, formulæ expressing those of these latter which belong to one kind in terms of those of the other kind, and formulæ for the fifty-four derivatives of Christoffel symbols of the second kind, obtaining finally the complete set of six Gauss and eight Codazzi relations between the coefficients of the fundamental and secondary quadratic differential forms Proceeding then to extend to a region the various notions already familiar in regard to a surface, he gives one chapter on linear curvature and lines of

curvature on a region, another on properties of geodesics and geodesic polar co-ordinates, a third and most interesting chapter on geodesic surfaces and the two measures of superficial curvature, the Riemann and the additive, associated with any orientation of a tangent plane at a point of the region, together with an investigation of their principal values, and he adds a fourth chapter on properties of loci of centres of curvature

In treating next of general properties of surfaces in a region as distinct from those of a surface in free homaloidal four-space, he is careful to point out the important properties of *immersion* possessed by the former relative to the regions in which they lie, as, for example, the measure of deviation of their geodesics from the geodesics of the region He obtains, however, all their spatial properties and curvatures as well, relating these wherever possible to properties of the region

After an illustrative chapter on ovoidal or quadric regions, the author gives next an introduction to the theory of minimal surfaces in four dimensions, first in regard to surfaces of minimal area existing in free space, and secondly in regard to surfaces whose area is minimal on a region contained in such a space These latter are, of course, of great importance as being the most obvious generalisations of the all-important geodesic curves, and Prof Forsyth obtains their characteristic property, namely, that their additive measure of regional geodesic curvature is zero Nevertheless, one feels inclined to think that these surfaces might surely be made to play a more important part than they seem to at present Prof Forsyth, however, evidently finds a more stimulating topic in his succeeding work on minimal regions

In Chapter xxiv the author sketches the theory of the various curvatures, linear, superficial, regional, etc, of a manifold of n dimensions in space of $n+1$ dimensions, obtaining also their principal values at a point He obtains finally, without reference to the absolute differential calculus, the principal values of all the curvatures at a point in terms only of those of the linear curvatures there One curious fact which emerges here is that although for surfaces in ordinary space the coefficients of the secondary quadratic form are not usually expressible in terms of those of the fundamental quadratic form, yet for a manifold of n dimensions in $(n+1)$ space $(n \geqslant 3)$, the corresponding coefficients are in general so expressible—a most interesting result

The rest of the work is taken up with a systematic investigation and geometrical interpretation of the concomitants of configurations in quadruple space For this purpose, Prof Forsyth uses by preference Lie's theory of continuous groups, which he believes to have certain definite advantages in this connexion over the method of the absolute differential calculus He considers in successive chapters concomitants of curves, surfaces, and threefolds, and includes in the last chapter complete systems of concomitants of a region, of grades three and four, in terms of which all others of the same or lower grade can be expressed J G S

Concerning Ceramics.

(1) *An Encyclopædia of the Ceramic Industries being a Guide to the Materials, Methods of Manufacture, Means of Recognition, and Testing the various Articles produced in the Clayworking and Allied Industries* By Alfred B Searle In 3 volumes Vol 1 Pp xxvii + 391 Vol 2 Pp 462 Vol 3 Pp 384 (London Ernest Benn, Ltd, 1930) 63*s* net each volume

(2) *Diatomaceous Earth* By Robert Calvert (American Chemical Society Monograph Series, No 52) Pp 251 (New York The Chemical Catalog Co, Inc, 1930) 5 dollars

(3) *Some Writers on Lime and Cement from Cato to Present Time* By Charles Spackman Pp xvii + 287 (Cambridge W Heffer and Sons, Ltd, London Simpkin Marshall, Ltd, 1929) 15*s* net

(1) IN attempting to arrive at an estimate of the utility of this complex work—Searle's "Encyclopædia"—the reviewer first commenced to trace out the ramifications of various subjects, but the constant distractions provided by interesting notes on totally different matters made progress slow and uncertain This method was then discontinued in favour of a system of 'dipping' on single topics, some of which were very familiar to the reader and some the reverse Continuing this method for a few months rather drastically altered his first impressions It is not difficult to find a variety of mistakes, and by these to frame a condemnation of the work What is more difficult is to view the work fairly from the point of vantage of the normal user, that is, one frankly seeking information

The book is full of pleasant surprises, on the other hand, much is omitted which one might fairly expect to find The author largely forestalls criticism of his imperfections by suggesting that the work, to be done perfectly, could not be accomplished by any man, and that, with all its imperfections, it might still be very useful, and so it is.

Its primary appeal, properly enough, is to those who have, so far, not had much contact with the object of their inquiry Nevertheless, there is an imposing array of articles of a very high standard Examples are the articles on electrical insulators and porcelain, hardness (of ceramic materials), plasticity, roofing tiles, rope haulage, and semi-dry process A very valuable feature of the book is the inclusion of fairly extensive references to the literature In this respect, if no other, the research worker and technical man, engaged in the task of collecting information on a new venture, are sure to be well repaid by including this book as a means of ready access

Although the work is, on the whole, well balanced, the reviewer feels that there is less vitality and intimate appreciation shown in the articles relating to pottery practice than in the other numerous, and chiefly 'heavy claywares', branches Information relating to kilns and ovens for fine ceramic goods seems disproportionately small, though this can be compensated by use of the references In this connexion, a misrepresentation of accepted theory is to be found in the article on continuous chamber kilns, where it is stated that "A further disadvantage is that hot air must pass downwards through the chambers to be heated, this is in the opposite direction to its natural flow, so that it is difficult to ensure the heat being uniformly distributed" The article on "Output of Kilns" might have been expected to give typical figures for different kilns and products, whereas the information afforded is limited to the acceleration of brick kilns and general remarks about chimneys, foundations, leakage, and wet fuel

The article on drying, though founded on the excellent treatment by Bourry, has a rather antique aspect for a modern work and would have been improved by the infusion of ideas from, for example, the work of Fisher and of Sherwood The author bravely copes with the causes of defects in drying, but seems to explain them in terms which leave the reader no wiser He refers to the importance of a knowledge of the ratio of the rate of evaporation to the rate of diffusion of water in the body, and that this ratio must be found for different materials, and *shapes*, by trial, before such defects can be cured Now, a ratio, being a number, needs an instrument, or instruments, for its measurement One never hears of such being used in practice, and, in fact, such problems are solved, on the works, by hit-and-miss methods Furthermore, it is certain that the diffusion of moisture in clay becomes more and more difficult as its shrinkage progresses, and a piece of clayware, particularly if thick, has a moisture gradient, with corresponding variations of resistance, from the inside out to the face The state of affairs is such that the ratio must be different for every part of the article and every interval of time during the course of the drying

In dealing with the high temperature side of ceramics, a large number of phase diagrams is reproduced Many of these are well placed, but some appear to be purely ornamental, as no reference is made to them, or explanation of the marked points, in the text Future editions will, no doubt, amend this

The article on barium carbonate should distinguish between the relative utility, as a cure for troubles due to soluble sulphates, of the precipitated substance and of ground witherite

In dealing with daub for kiln wickets, etc, a better statement should have been given of the making of a suitable mixture, sufficiently adherent, and, above all, free from such shrinkage as gives rise to cracks on drying

The question of filtration of ceramic body slips is one of very great importance, and whilst many aspects are well treated, it is regretted that due emphasis is not placed on the fact that clay filters itself, the filter cloth being merely a support, and that, being to some extent colloidal, the pressure of filtration has much to do with the ultimate residue of water in the cake, apart from its effects on the speed of working

The reviewer would like to put forward a plea for that important clay working area, North Staffordshire, in the matter of the use of the term marl It is the custom of that district to refer to the local fireclays as 'marl', without any suggestion that they are inferior in refractoriness due to the presence of lime, which they are not The confusion which arises is one which could readily be cleared up in a work of this nature

Among definitions which will prove misleading to the student, though clearly not intentional, are "Kation—One of a pair of electrodes", and, under "Quartz", "angular rotation in degrees per min" There is a number of other mistakes, doubtful statements, and cases of bad construction in this article They appear sporadically in a work which is, on the whole, well edited The article on plasticity, in spite of its general good quality, suffers in this way The thickness of the water layer on clay particles in a plastic mass is given as 1 00005 in, alumina- for alumino-, W E Emery for W E Emley, Emerly for Emery, and Jachum for Jochum

The tables giving the composition of seger cones are in need of editorial attention

The reader of this rather fearsome sample of objections and errors might be influenced to avoid the book That would not be the reviewer's wish, considering the very wide scope of the work, its undoubted helpfulness for ready reference, and the considerable opportunities afforded by the literature references of eliminating errors by closer inquiry Mr Searle is certainly to be congratulated He has greatly lessened the labour for those who may follow in his footsteps, and, in the meantime, provided a useful guide for busy men

(2) Calvert's "Diatomaceous Earth" is a very worthy addition to the American Chemical Society's Monograph Series, which already includes books of the greatest interest to the ceramic technologist Amongst these may be mentioned Sosman's 'Properties of Silica", Svedberg's "Colloid Chemistry", and Vail's Soluble Silicates in Industry" The use of diatomaceous earth, or kieselguhr, for high temperature insulation has very greatly increased in the last decade, and no better subject for a monograph, collecting existing information in a useful form, could have been chosen The same remark applies, with equal if not greater force, with reference to its use as an aid to filtration, notably of sugar syrups, and as an addition to Portland cement Whilst these are the chief uses of kieselguhr, it has many others depending on its fine pore structure, polishing powers, and reactivity with lime and alkalis

Calvert deals with the natural origins, properties, and uses of his material in a manner which leaves little to be desired The illustrations and references are copious and well chosen, ready reference is facilitated by good indexes The paper and binding are of good quality Very few adverse criticisms seem possible a few cases of faulty construction and printers' errors occur For those who prefer to think of furnace temperatures in terms of Centigrade degrees, the almost invariable use of the Fahrenheit scale involves frequent mental arithmetic The importance of the Danish deposits has not, perhaps, received its due, but as the development in this area has been chiefly recent in date, it will perhaps receive more attention in a future edition The work undoubtedly deserves a special place on the bookshelves of every ceramic technologist

(3) All those who have cause to search the literature for historical information on calcareous cements and lime will be grateful to Charles Spackman for collecting the results of his researches in this volume The work commences with short definitions of a large variety of cements, and an index to the names of the authors whose works are dealt with chronologically in the main body of the book The works abstracted or described range from Marcus Porcius Cato, 234–149 B C, to the modern works of Knibbs and Eckel and the publications of the Building Research Board The reviewer has noted a few minor errors, but, on the whole, the book has been well edited It concludes with a suitable subject index S R HIND

A Late Greek Manuscript on Alchemy

Union Académique Internationale Catalogue des manuscrits alchimiques grecs Publié sous la direction de J Bidez, F Cumont, A Delatte, Sir Frederic Kenyon, O Lagercrantz, J Ruska et C O Zuretti Tome 7 Anonymi de arte metallica seu de metallorum conversione in aurum et argentum Edidit C O Zuretti Pp lx + 466 (Bruxelles Maurice Lamertin, 1930)

THE earliest treatises on chemistry were composed in Hellenistic Egypt (Alexandria) during the first centuries of the Christian era. Their language was Greek (κοινή), and their continuations in the Byzantine period, for example, under Heraclius (A D 610–641), present no new features After the Mohammedan conquest of Egypt in A D 640, the treatises passed into an Arabic dress, and from about A D 1100 they arrived, in a sadly corrupted form, in the west in the shape of Latin versions (or 'perversions') made in Spain The original Alexandrian treatises have been published, with translations, by Berthelot and Ruelle ('Collection des alchimistes grecs", 3 vols, Paris, 1887–88), and, although from time to time threats of an 'improved' edition have been put forward rather fretfully by German scholars, this publication is likely to remain for some time to come the basis of our knowledge of the earliest chemistry The principal manuscripts and their contents have been known for a long time, in the selection of texts for publication or republication the advice of a chemist would no doubt prove useful, since the interest and value of such texts vary considerably

That the Latin versions were sometimes retranslated into modern Greek was well known Berthelot ("La Chimie au moyen âge", vol 1, p 155, *ib*, "Introduction à la chimie des anciens et du moyen âge", p 207) had directed attention to a case in point, the work "Πέτρου τοῦ Θεοκτονίκου

πρὸς τὴν τέχνην τῆς ἀρχημίας", which is merely a translation of a Latin work attributed to Albertus Magnus Some of the "Traités techniques" published by Berthelot ("Collection", 321 f) also appear to be of this character

The work edited by M Zuretti, with great care and skill, which is now before us, appears to be a translation made about the fourteenth century in Italy from a Latin treatise or treatises, probably in turn translated from Arabic sources The date and language of the treatise will be sufficiently obvious from the small chrestomathy which follows

ελέξιρ	*μποτον μπαρβοτον*
ἐν φουρνέλου,	*τὸ ατιγκὰρ εν ἔλαιον ιεροισολιμιτικὸν*,
ἐν ὕδατι καυστικῷ,	*εν ὀθονίῳ πικνῷ*;
αλὸς νίτρου καὶ βοραχίου,	*ἐν φιάλῃ* (for a flask)
ἐπὶ νάφθαν,	*ρὸτουλον αρσενικὸν*,
βάλε εις ουρινάλιον,	*ὕδωρ ζωῆς* (*aqua vitae*),
αλὸς αμμωνιακου,	*ἅλας ἀλκαλὶ καλουμένης σόζα* (*soda*),
εν σιέλῳ (*axungia*),	*ἅλας της πέτρας* (*sal petrae*)
ἄλας βίτρουμ	*ἅλατος τοῦ ταρταρου*

The theory of the composition of metals from mercury and sulphur, which is attributed to Hermes Trismegistus, is given in the usual form the four 'spirits' (that is, volatile bodies, a designation which appears in the Alexandrian treatises) are mercury, sulphur, arsenic, and sal ammoniac, although the latter is said to be really a salt, not a spirit The word *xerion*, which usually means simply 'powder' (*λείωσον εἰς ξηρίοι*), is, for some reason, not translated by the editor An unusual feature is the classification of some metals as 'masculine' (for example, iron), which may have an astrological basis

The only actual authority quoted in the text appears to be "Solomon the soldier" (*κατα τον Σολομῶντα τὸν στρατιώτην*), although Arnold of Villanova appears in the table of contents Sublimation is *ἀνάβασις* the Alexandrian term is *ἄρσις* Some of the recipes have the ending characteristic of a Byzantine treatise *σὺν θεῷ* (Stephanos in Ideler's "Physici et medici Graeci minores" vol 2, pp 199-253, each chapter, *πρᾶξις*, title, of which has it) There is an attempt at a lexicon of concealed names (p 174), and no doubt many of the names of substances in the recipes are of this character, since the chemical operations as given are frequently impossible A very curious name is *ἅλας τὸ ἀλαμπρὸτ* (*sal alembroth*, used, according to Kopp, "Geschichte", vol 4, p 195, for a mercury salt by Paracelsus "or perhaps earlier in our treatise it is a mixture of alkali salts) Mineral acids (*ὕδωρ δε χαλκάνθου*) appear, as well as rectified alcohol

Several words are left untranslated by the editor (1) *κηρον νεοὺμ τίμιοι* (p 216), given as *ceronneum pretiosum* (? "precious ointment", as *μύρον βαρυτιμον* in Matthew xxvi 7), the translation on p 217 seems defective in some respects, *ceration* is an operation described in the early Alexandrian treatises and is derived from the old encaustic painting in four colours black, white, yellow, red, in wax, these colours being mixed on the palette, *κηροτακις*, over a small brazier (shown in Berthelot's, "Introduction", p 146 but there erroneously called a 'bain marie"), (2) *τζηρικι* (probably related to *ξηριοι*), (3) *σαρειπινουμ* (indexed as ? franco gallice *sapin* ? ', which is improbable *serapinus* is gum arabic in Ruhland's 'Lexicon", 1612, p 432), (4) *μαστιχιον*, which dissolves iron and all bodies and is *μυστηριον θαυμαστόν*, perhaps an acid distilled in the alembic (instrument de verre, en forme de *μαστταριοι*," in Synesios, Berthelot, 'Introduction , p 164) (5) *οκοι* (p 320, perhaps *ὦχροι*, as it is among yellow and red colours) (5) *ινδαικοι* (? *ondanique* Chinese iron), etc

The mention of a reverberatory furnace (*φουρνελλιοι ῥεβερμπερατιονις* p 262, etc) seems an early reference reverberatory fire (*πῦρ ῥεβερμπερατιζόνις*, p 308) is also used The use of the reverberatory furnace in England is said by Bishop Watson ('Chemical Essays", vol 1, p 33, vol 3, p 273, where it is called a *cupola*) to date only from the end of the seventeenth century

The Latin translation appears to be technically fairly good (*θειοι* translated as *aes* on p 383 has escaped the list of corrigenda on p 465), the requirements of chemists would better be met by French or English The chemical interest of the treatise is small, most of the recipes given seem to have been copied unintelligently by the compiler of the manuscript, which appears to contain material of very various dates Some parts are derived from Alexandrian or early Byzantine material, others have certainly come from Arabic versions, whilst others seem quite late and are probably derived from Italian recipe books almost contemporary with the date of compilation of the MS It is perhaps noteworthy that the treatment of pigments finds no place in the treatise, whilst it occupies most of the space in Italian recipe books of the same or somewhat later period

We have to thank M Zuretti for the very successful result of his difficult task of editing this interesting work and for the excellent index which accompanies it

J R PARTINGTON

Our Bookshelf.

Allen's Commercial Organic Analysis Vol 8 *Glucosides, Non Glucosidal Bitter Principles, Enzymes, Putrefaction Bases, Animal Bases, Animal Acids, the Cyanogen Compounds, the Proteins, the Digestion Products of Proteins* By the Editor and the following Contributors Julius Grant, G Barger, K G Falk, Philip B Hawk and O Bergeim, G H Buchanan, S B Schryver and H W Buston Editor Dr C Ainsworth Mitchell Fifth edition, revised and partly rewritten Pp x + 761 (London J and A Churchill, 1930) 30*s*

NEARLY twenty years have elapsed since the issue of the corresponding volume in the fourth edition of "Allen's Commercial Organic Analysis" Probably in no field of analytical work have more changes taken place during this period than in the subject matter under review, and particularly in the sections on nitrogenous constituents of animal and plant materials The present volume is, therefore, practically a new book The general subject is considered in a series of well written monographs by specialists in their respective subjects, and the high standard of the previous volumes has been maintained

As pointed out by the editor, there must of necessity be a certain amount of overlapping in an exhaustive work of this type written by a large number of experts Thus, enzymes are considered in their relation to glucosides and elsewhere in the book from a different aspect, namely, in their connexion with the hydrolytic dissociation of proteins On the whole, however, the book gains by such repetition, since the subject matter is considered by each specialist from a different aspect Again, in a consideration of the subject matter of 'animal bases' certain related compounds have been discussed already in previous volumes (pyridine derivatives, mononamines, etc), while some related compounds are reviewed in the section on 'putrefaction bases' In this section, therefore, the author has been able to omit these from his review Even with these omissions this section on 'animal bases' extends to more than 180 pages, and constitutes a very complete thesis in itself, on this difficult subject The sections in the present volume on the analysis of proteins and on the digestive products of the proteins are the last contributions of the late Dr S B Schryver to this branch of chemistry It is of interest to note that it is intended to include a tenth volume in this series which will include recent advances and also a complete index to the whole series

J REILLY

Gestalt Psychology By Prof Dr Wolfgang Köhler Pp xi + 312 (London G Bell and Sons, Ltd, 1930) 15*s* net

THE author in his preface apologises for his difficulty in presenting *Gestalt* psychology in a foreign language, one may say at the outset that his English is much better than that of many writers to whom it is the mother-tongue The author also points out that the subject matter as presented resembles a promising start rather than a complete achievement It is a pity that this useful point of view is not maintained as the tone of the actual exposition, for that appears to be rather unnecessarily controversial and dogmatic

To express the *Gestalt* theory in a few words is impossible It arose primarily out of the experimental study of space perception, and the results of this study led to dissatisfaction with the prevailing theories and the formulation of what is known as the *Gestalt* theory The word *Gestalt* has too much significance, unfortunately, in the German language, and its English equivalent too little It is used to mean 'form' or 'shape', but also a state or process, or a segregated whole, and the theory is applied to most of the phenomena of sense perception, and then to processes of thought The author discusses the properties of organised wholes, behaviour, association, reproduction, and insight, from this point of view The varieties of directed attitude are held to be due, not to instincts or pre existing drives, but to the actual situation In experimentation the Gestaltists have done excellent work, and their challenge has been a useful stimulus, but a book of this size ought not to omit such contemporary work as that of Prof Spearman

The hypotheses put forward involve both physiology and physics, and the truth cannot be estimated yet "All experienced order in space and time is a true representation of a corresponding order in the underlying dynamical context of physiological process" We do not know Although there are constant references to the experimental data, yet few details are here given Less repetition and fewer analogies from physics would have added considerably to the value of this nevertheless important communication

The Aquatic (Naiad) Stage of the British Dragonflies (Paraneuroptera) By William John Lucas (Ray Society Volume No 117, for the Year 1930) Pp xii + 132 + 35 plates (London Dulau and Co, Ltd, 1930) 25*s*

IN this work the author describes and figures the last immature instar in each of the forty-two species of dragonflies found in Great Britain Since the whole of the early life of these insects is passed in water, and lasts on an average about two years, it is not surprising that the complete biology of very few of the species has been followed There is consequently a large field open for the enthusiastic naturalist to explore as regards these insects In the introduction to this volume the general structural details of the immature stages of dragonflies are explained, and with this information the reader is enabled to pass on to the diagnostic keys to the nymphs or naiads, as they are variously termed, arranged in families, genera, and species The use of these keys will enable any given example to be traced down, and this preliminary determination can then be confirmed by reference to the detailed specific descriptions given in the general text

At the end of the book there is a wealth of coloured and half-tone plates, which are reproduced in all cases from the author's personal drawings In these plates the entire nymph, or naiad, is accurately figured, together with the mentum and palpi In the suborder Zygoptera one of the caudal lamellæ is usually also represented A monograph so complete as the present one is obviously the result of many years' patient search and observation In some cases the living stages have been procured and the descriptions and illustrations made from these, in others, spirit material has been utilised, while for a considerable number, recourse had to be made to the exuviæ out of which the imagines had emerged The author has appended to his descriptions notes relative to the habits, etc, of the different species Although all the species are carnivorous, little seems to be known relative to their actual prey and whether they exercise much discrimination in this respect

The present volume is well up to the standard of other volumes issued by the Ray Society, and both that body and the author are to be congratulated upon its production A D I

The Newcomen Society for the Study of the History of Engineering and Technology Transactions, Vol 8, 1927–1928 Pp xi + 196 + 23 plates (London The Newcomen Society, 1929) 20*s*

VOL 8 of the *Transactions* of the Newcomen Society contains ten papers read during the winter 1927–28 and during the summer meeting of the latter year at Stourbridge, two notes and communications, a subject list of books and pamphlets relating to the history of technology, 1926–30, a list of members, the annual report, and 23 finely produced plates As usual, the range of subjects is a wide one, the papers including those of Mr E W Anderson on the development of the organ, of Mr T Rowatt on railway brakes, of Mr J E Hodgson on James Sadler of Oxford, and of Mr J W Hall on the making and rolling of iron

Two papers respectively by Engr Capt E C Smith and Mr L F Loree deal with the early history of steam navigation in England and America In that by the former is an account of the machinery of the s s *Victory* in which Capt John Ross set out in 1829 to discover the North west Passage From Ross's account of his long sojourn in the north, it was known that the machinery proved a failure, but hitherto nothing was known of its construction Particulars and sketches of it were found a year or two ago in the note-books of Simon Goodrich which were preserved in the Science Museum, and some of his sketches have been reproduced in the *Transactions*

The summer meeting gave an opportunity for several interesting communications on the early industries of the Stourbridge district One of the 'notes' included in the volume is a long and valuable paper by Col N T Belaiew on the Sumerian mina, its origin and probable value, while another by Dr Carl Sahlin recalls the work of Thomas Lewis and Samuel Owen, two British pioneers of mechanical engineering in Sweden

Myths and Legends of the Australian Aboriginals By Dr W Ramsay Smith Pp 356 + 38 plates (London, Bombay and Sydney George G Harrap and Co, Ltd, 1930) 21*s* net

DR RAMSAY SMITH classifies the myths and legends of the Australian aborigines which he has collected in this volume into 'origins', that is, stories of the creation and beginnings of things, animal myths, religious, social, and personal myths, and has strung them together in the form of a connected narrative by notes on customs and beliefs cognate to each class These notes give the uninstructed reader a general view of aboriginal culture as a background for the stories Dr Ramsay Smith is fully alive to the importance of aboriginal legendary lore in its bearing upon their institutions, and it is therefore surprising to find that, even though he disclaims any intention of giving a scientific exposition of Australian mythology, there is no indication of where and when the material was collected Except in one or two cases, the name of the tribe in which the myth occurred is not mentioned All that we are told is that the myths refer to "only a few localities in Australia and only a few tribes in them" As the stories, which are very much 'written up', bear very directly upon problems of aboriginal belief, this is a grave defect —all the more, perhaps because the book is intended to be popular

La Lorraine metallurgique Par Axel Somme Pp viii + 250 + 7 planches + 12 cartes (Paris Éditions Berger Levrault, 1930) 30 francs

IN spite of their low iron content, the minette deposits of Lorraine are of great importance Before the European War they were partly in Germany now they lie in France except for a small area in Luxemburg, which will probably be exhausted in half a century Prof Somme has made a close study of the geographical and economic conditions in these relatively new iron ore districts with their rapidly growing towns He has produced a monograph of considerable value, tracing the growth of the industry, its lessening dependence on Ruhr coke its markets and lines of export, and the main labour problems which are entailed He discusses even the effect of the industry on agriculture in Lorraine and Luxemburg The book is well documented and has a number of sketch maps and illustrations

Philosophy of a Biologist By Sir Leonard Hill Pp viii + 88 (London Edward Arnold and Co, 1930) 3*s* 6*d* net

THIS little book is a review of our present knowledge and views by a distinguished physiologist It will be read with pleasure and interest by all scientific men, whether or not they agree with the author's endeavour to suggest that "modern science has brought us to the conception of a power eternal, infinite, unknowable energizing all in the universe, the dead no less than the quick"

Letters to the Editor

[*The Editor does not hold himself responsible for opinions expressed by his correspondents. Neither can he undertake to return, nor to correspond with the writers of, rejected manuscripts intended for this or any other part of* NATURE. *No notice is taken of anonymous communications.*]

Stellar Structure

IT is only with some qualms that an outsider can enter into the discussion of questions of stellar structure, but I feel that Sir James Jeans is speaking more favourably of Prof. Milne's theory than he thinks when he says that it contains little that has not been anticipated either by Sir Arthur Eddington or by himself.[1] A theory that will combine the good points of Eddington's and Jeans's theories is precisely what observers of the progress of astrophysics have long wished to see. Jeans requires a liquid interior to explain binary fission; Eddington says that owing to ionisation the gas laws must hold through most of the interior. Eddington, assuming that the gas laws hold throughout the interior, infers the mass-luminosity relation, which is verified by observation except for the adjustment of a single constant. Neither theory appears to account for the facts explained by the other, and there must be something that both authors have overlooked. It seems to me that the chief recommendation of Prof. Milne's method of attack is that it foreshadows a means of finding out what this is.

As to Prof. Milne's results, the most striking seems to me to have escaped comment. In his forthcoming paper[2] he gives results for the companion of Sirius, containing an adjustable parameter β. If we take this equal to 0·28 we get

	Theoretical	Observed
Mean density (gm./cm.^{3})	6×10^4	6×10^4
Radius (cm.)	$3{\cdot}4 \times 10^9$	$1{\cdot}9 \times 10^9$
Effective temperature (degrees)	6000	8000–10000

An agreement in order of magnitude for matter so far removed from any state known in the laboratory must be impressive, particularly since, as Prof. Milne indicates, the theory is capable of further development.

The generation of stellar energy has long been an intractable problem. Eddington recognises the difficulty of accounting for it at the temperatures given by his theory. Jeans deals with it by introducing radioactive elements of higher atomic number than uranium. Whether this is an assumption or an inference, mere radioactivity, as usually understood, scarcely seems likely to give so great a secular diminution of mass as the stellar time-scale requires. Mutual annihilation of protons and electrons will do it, but this does not take place in ordinary radioactive processes. The great recommendation of Prof. Milne's theory is that it provides temperatures in the central regions of a star such that this mutual annihilation can be explained without going beyond current physical theories. On the other hand, the amount of generation given still needs quantitative test.

The defect of Milne's and Eddington's theories alike seems to be that they require too high a value of the stellar opacity, as was pointed out by several speakers in the recent discussion at the Royal Astronomical Society. Is it possible that this is because the chief mode of transfer of stellar energy is not by radiation but by vertical convection currents? All existing theories are against this suggestion, yet two circumstances point towards it. The granular appearance of the surface of the sun, as seen in a photograph taken in monochromatic light, strongly resembles that noticed by Bénard[3] and later workers[4] in the surface of a thin layer of liquid that has become unstable under a vertical temperature gradient just exceeding the adiabatic; also that shown in photographs of the upper surface of strato-cumulus clouds. Against this we have the fact that Prof. Milne seems to have shown[5] that the temperature gradient in the photosphere does not reach the adiabatic except possibly inside a sunspot. Secondly, if we *demand* a temperature of the order of 10^{10} degrees for the generation of subatomic energy, the whole of this generation must be in a small sphere about the centre of the star, and radiation may be unable to dispose of it at a gradient under the adiabatic.

Current theories, by assuming generation throughout the star, must give too low a gradient in the central regions. If this suggestion is correct, vertical currents must be generated, and these will redistribute the heat so as to keep the gradient near the adiabatic for a stream of matter carrying its radiation with it. This has been discussed by Prof. Milne, apparently with adverse results, but I am still inclined to think that his discussion may have constructive and not merely destructive value.

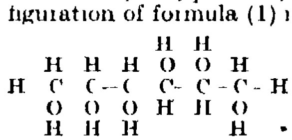
An X-Ray Study of Mannitol

IN NATURE of Jan. 3, p. 11, Miss Thora C. Marwick gives the results of an X-ray examination of mannitol. I have recently completed an investigation of the structure of *d*-mannitol in the Chemistry Department of the University of Edinburgh, and have obtained the following results from the X-ray analysis:

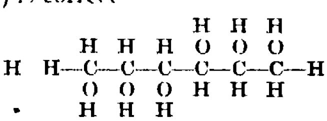
Space group, Q^4; $a = 8{\cdot}66$ A., $b = 16{\cdot}58$ A., $c = 5{\cdot}50$ A.; calculated density, 1·522 gm. per c.c.; 4 molecules per cell.

Groth (*Chem. Kryst.*, vol. 3, p. 431) reports on two crystalline modifications of *d*-mannitol; the β-form which is always obtained by crystallisation from water is the form which was examined.

Irvine and Paterson (*Jour. Chem. Soc.*, 105, p. 898; 1914) have shown that the terminal primary hydroxyl groups of the *d*-mannitol molecule do not appear to possess free rotation, but assume preferentially the fixed positions shown in formula (1). A second possible configuration is shown in formula (2), but a comparison of the reactive powers of the terminal hydroxyl groups made by Irvine and Steele (*Jour. Chem. Soc.*, 107, p. 1221; 1915) proves that the configuration of formula (1) is correct.



(1)



(2)

W. T. Astbury and Miss K. Yardley (*Phil. Trans.*, A, vol. 224, p. 221; 1924) show that in a crystal belonging to the space group Q^4, and having four molecules in the unit cell, the molecules must be asymmetric. Of the two possible configurations shown in formulæ (1) and (2), that of the latter possesses a diad axis of symmetry, while that of the former cannot possess any symmetry. The structure of the molecule of *d*-mannitol within the crystal is therefore represented by formula (1). This structure was also assigned to *d*-mannitol by Irvine and his collaborators examining the substance in solution.

An investigation of the crystal structure of *d*-

mannose is now nearing completion, and the results of the X ray analysis of d mannitol and d mannose are to be incorporated in a paper which is in preparation

GEORGE W. McCREA

University, Edinburgh, Jan. 12.

The Nature of Time

EDDINGTON[1] has argued that the second law of thermodynamics definitely requires a one way flow of time, although all other physical laws are equally valid for $+t$ and $-t$. Lewis[2] has taken the opposite stand, and concluded that entropy entails no temporal implications, hence time must be considered as twofold. Both agree that consideration of an individual particle yields no clue to the dilemma.

Pressing Eddington's 'time's arrow' argument it appears theoretically possible to interconnect all elementary volumes of equal entropy in the universe by hyper surfaces orthogonal to the time lines tangent to 'time's arrow'. Since entropy is a relativity invariant, this would determine a unique lattice for separating space and time, contrary to the principle of relativity.

It has occurred to us that since the only real argument in support of one way time is derived from a consideration of statistical assemblages, it may be that time itself is discrete and should be statistically treated. To our knowledge this possibility has not previously been suggested, although Ives[3] has recently pointed out the intimate association of frequency (and therefore time) with mass and energy, both of which have been found to be discrete.

Pursuing the thought a little further, if the unit of time were intimately connected in some way with the electron or proton, some light might be shed on the mystery of quantum jumps. Since h/mc^2 has the dimensions of time, a possible value for a quantum of time would be 8.12×10^{-21} sec. obtained by substituting the mass of the electron for m in the above expression.

If time is found to be essentially discrete and statistical then, since action and matter are already so accepted, the postulate of discrete or statistical space and electric or magnetic fields would also become highly probable.

Equipotentiality of the Amphibian Eye Primordia

THE experiments referred to below are concerned with the problem of the regulative power of embryonic *anlage*, the study of which has been taken to prove the equipotentiality of the eye primordia in amphibian embryos in the stages following the closure of the medullary folds. In *Pleurodeles waltli* it has been shown[1] that two optic vesicles may fuse together when that of the donor is transplanted in the close proximity of the optic vesicle of the host, keeping the same orientation of the normal position in the implanted eye. The degree of fusion depends upon the size of the removed portion of the vesicle in the host, and varies from that of double eyes partially fused to single eyes of larger size than the normal which have developed by complete fusion of the two optic vesicles, which regulate its size afterwards, provided that the lens is not double.

By transplanting the optic vesicle of the donor dorsally and ventrally, cranially and caudally, or in the outer portion of the vesicle in the host, it has been possible to show the morphogenetic equipotentiality of the eye primordia. This is further shown by the fact that the anterior, posterior, ventral, dorsal, or medial halves of the vesicle may regulate and give rise to a normal but smaller eye. Such results have been extended by myself in further experiments on *Triton*, *Axolotl*, *Rana esculenta*, later by Detwiler[2] in *Rana fusca*. More recently, in some experiments on lens induction in *Rana catesbiana*, I repeated my own experiments on the fusion with the same results.

The chief results concerning the extent of fusion of two optic primordia in the experiments already described, together with the regenerative power of the optic vesicle or its compensatory regulation, have been dealt with. Our experiments have shown that the easiest way to get complete fusion is to remove a certain amount of the exterior part of the host vesicle, transplanting in its place the vesicle of the donor with the same kind of operation, it has been possible to get the clearest cases of regulation in the medial half of the vesicle. In this way the potentiality of the optic vesicle's constituents has been analysed, controlling each half of the vesicle delimited by the transversal, frontal, and sagittal planes.

It has been found also in my fusion experiments, that there exists a very close relation between the behaviour of the lens and the fused eye. Examples of such are cases in which the lens ectoderm was not transplanted with the optic vesicle and the double eye arose with a normal size lens; cases of transplantation of the optic vesicle with the overlying ectoderm which gave rise to double eyes with double lenses; or cases of a single lens produced by the fusion of two lens primordia. In the first case the regulatory reduction of the size in the double eyes seems to be accelerated, the same occurring in eyes with single fused lens; in the latter case the presence of two lenses causes less regulation of the form and size of the eye, and in some cases this regulation does not occur at all. A point of particular interest which has been investigated more carefully is the reaction of nerve centres to the double eye (resulting from complete fusion of two optic vesicles) in which case the number of nerve fibres growing in the thicker nerve has been increased by the implantation of an additional optic vesicle. There is always a very clear hyperplasia of the central nervous system and the amount of the grey matter in the wall of the mid brain on the side opposite to the double eye increases because of the greater number of the ingrowing nerve fibres.

A similar reaction has been shown for a single eye transplanted in the ear region by May and Detwiler[3] in *Amblystoma*, by May[4] in *Rana temporaria* and *Bufo vulgaris*, but in this new condition established by a double nerve which belongs to a larger sense organ this reaction has a particular significance for its quantitative nature. These effects are closely similar to the hyperplasia found by Burr[5] in *Amblystoma* following the fusion of two nasal pits, and to the hyperplasia described by Twitty[6] when a large *Amblystoma tigrinum* eye is transplanted in its normal position in *A. punctatum* embryos.

In my experiments the size of the larger eye, sometimes double that of the normal and originating by complete fusion of the two eye primordia, the normal and the grafted one, and the consequent disturbance of the number of ganglionic cells in the double retina, causes also a real shifting of the grey matter cells in the brain toward the ingrowth of the supernumerary nerve fibres. My new experiments in *Axolotl*[7] have shown the possibility of such an increase of the amount of the grey matter as a result of the transplantation of a supernumerary single eye in a different region of the head, in other words, with abnormal connexions with the brain in the olfactory

optic and otic region This change of the grey matter occurs also in the brain tissue belonging to the donor which has been involved in the transplantation either in the anterior, middle or posterior brain In any event, the shifting and increasing of cells in the grey matter are always quantitatively greater with a double fused nerve Therefore the affinity between nerve centres and sense organs is shown by a reaction of growth (cell division) which occurs in the region corresponding to the supernumerary sense organ The latter, for that reason, must have a very clear influence on the development of nervous centres

These results are in harmony with the recent investigations of Harrison[8] concerning development and growth of heteroplastically transplanted eyes

Periodic Fluctuations in a Vertical Temperature Gradient

THE accompanying diagram (Fig 1) suggests a striking example of wave motion in the vertical temperature gradient at St Hubert Airport near Montreal during a large inversion of lapse rate in the

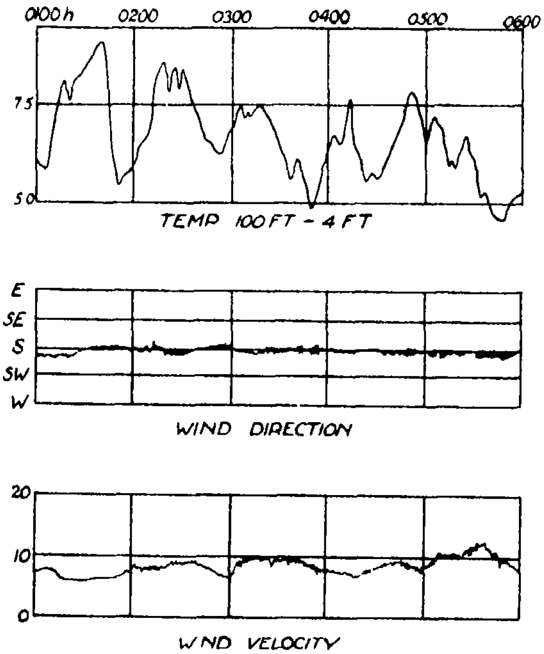

FIG 1

early morning of Oct 12 1930 The upper curve shows the temperature at 100 feet above the ground minus that at 4 feet in degrees Fahrenheit The lower curves show the velocity and direction of the wind at 60 feet

Five complete waves occur in the vertical gradient between 0105 hours and 0520 hours with an average period of about 50 minutes The gradient in question was measured by platinum resistance thermometers continuously ventilated by a fan

The barometer was very steady, and the wind unusually so At this time, the station was about 300 miles from the centre of a large, slow moving anticyclone about 1500 miles in diameter Very light winds had prevailed for three days, and unseasonably high daytime temperatures There is no information about cloud at this station at night, but the skies were cloudless for two days before and the day after, which renders it likely that the night was clear The country to the south of St Hubert (from which direction the wind was blowing) is very flat for some miles

During more or less stationary anticyclonic conditions, fluctuations of the same general magnitude often occur in the early hours of the morning but in this example the periodicity is especially apparent

The Value of M/m

PROF H S ALLEN has directed my attention to the short account in NATURE of Dec 13 p 942, of a recent paper by Sir Arthur Eddington, in which Sir Arthur suggests on theoretical grounds that $M/m - (136)^2/10 - 1849\ 6$ Prof Allen in 1915 suggested[1] that a relationship of this type might be true

Assuming that $M_H/m = 1850\ 6$ and taking the values of the Faraday constant and atomic weight of hydrogen as given by Birge,[2] I deduce

$$e/m \quad (1\ 7719 \pm 0\ 0001_3) \times 10^7$$

Now this is not only higher than I estimate[3]

$$\left.\begin{matrix} 1\ 7688_2 \pm 0\ 0006_3 \\ 1\ 767_7 \pm 0\ 001 \end{matrix}\right\} \times 10^7$$

but also is higher than the values given by Birge[4] higher than two recent determinations[5] and higher than all the final values tabulated in the Handbuch der Physik (22, p 81) and in J J and G P Thomson's Conduction of Electricity through Gasses (1, p 264) with the exception of the one higher determination of Classen This seems to me sufficient evidence to show that M_p/m cannot be exactly 1849 6 There is however more evidence to this effect

Using the estimate $e/m = (1\ 7719 \pm 0\ 0001_3) \times 10^7$ together with Rydberg's formula and Eddington's equation $hc/2\pi e^2 = 137$ (experimental evidence for which I explained in my December paper) I deduce

$$e - (4\ 771_6 \pm 0\ 0004) \times 10^{-10}$$
$$h \quad (6\ 537_3 + 0\ 0009) \times 10^{-27}$$

(for the subsidiary data I have used Birge's values) These estimates of e and h may at first seem acceptable enough but when they are compared with the determinations of h by five other methods as given by Birge[6] using the graphical method given in my paper, it is found that all five deviate from the present estimates *in the same sense* As there is only a probability of 1/16 of the five being all in error in the same sense I can only conclude that this is more evidence against the equation $M/m = 1849\ 6$

Giant Oysters

DR ORTON[1] has given the dimensions and weight of two exceptionally large specimens of *O edulis*, which have led to interesting comparisons The closely allied southern Australian species, *O sinuata* (*angasi*), normally grows to a large size, specimens 1 lb in weight being quite common The largest specimen of this species which I have seen weighed when wet, but without meat, 2 lb 3 oz , the dry shells weigh 1 lb 4½ oz This oyster is 6½ inches long, 7 inches broad, and 3 inches deep It was gathered in George's Bay, Tasmania, and local residents informed me that they have seen considerably larger samples

The largest oyster we have here in our collection is a specimen of *O crista-galli* from the Great Barrier Reef, North Queensland (Fig 1) It weighs (dry shells)

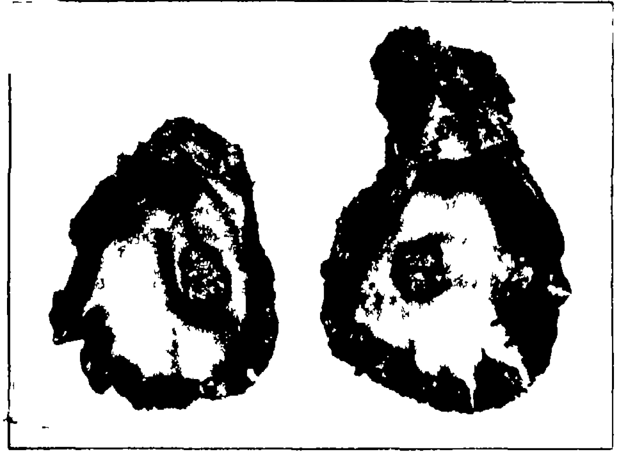

FIG 1 —*Ostrea crista galli* from the Great Barrier Reef North Queensland

4 lb 2½ oz When alive it probably weighed in the vicinity of 5 lb Its dimensions are length 9¾ inches, breadth 6½ inches, depth 4½ inches This oyster had attained a great age, as indicated by the extraordinary development of the umbo of the right shell, which is 3½ inches long Saville Kent, in his "Great Barrier Reef of Australia", p 244, states that oysters of this species 'not unfrequently weigh as much as from 5 to 7 lb and have a diameter of from eight to twelve inches"

It will be interesting to learn which species of the world wide genus *Ostrea* attains the largest size

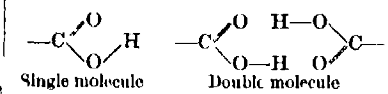
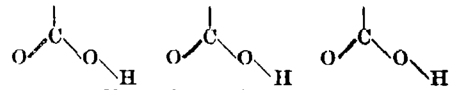
Adhesive Forces in Surface Films

DR N K ADAM's contention (NATURE, Dec 20, 1930), that the molecules of a fatty acid on the surface of water may be held together by the mutual attraction of the 'heads', even when the hydrocarbon chains are in such violent agitation as to have lost all adhesive force, may be thrown into a more precise form by making use of the conception of the co ordination of hydrogen,[1] which has also been described more picturesquely as "Bigamous Hydrogen"[2] This conception serves to account for the formation of the acid fluoride ion [FHF]$^-$, but was first applied by Pfeiffer,[3] so long ago as 1913, in order to account for the lack of acidic properties in *o*-hydroxy anthraquinone

The interaction between contiguous –OH and >C=O groups, which Pfeiffer postulated, has already been used to account for the peculiar properties of the two radicals when united to form a carboxyl group,[4] and for the formation of double molecules both in the vapour and in crystals of carboxylic acids It is, therefore, an obvious step to make use of it also to account for the adhesion between contiguous molecules in a monomolecular film of a fatty acid on the surface of water The three methods in which carboxyl groups may be affected by this co ordination may be indicated by the following formulæ, where the hydrogen is supposed to be under the influence of both of the oxygen atoms to which it is adjacent



Single molecule Double molecule



Monomolecular film

Spectrum of Doubly Ionised Iodine

THIS spectrum has been under investigation for some time past in the visible and ultra violet regions, and it has been found that a good many of the strong lines owe their origin to the terms of $2O_2P_1$, $2O_2P_2$, and $2O_2P_3$ electronic configurations All the quartet terms for these have been recognised, the lines originating from them having been obtained by a consideration of the spectra of doubly ionised indium tin, and antimony which have been elucidated by various investigators In spite of the difficulties of correctly estimating the intensities of lines for highly ionised elements, the multiplets in the present case follow the usual intensity rules fairly well The $2O_2(P_1 \leftarrow P_2)$ and $2O_2(P_2 \leftarrow P_3)$ lines are grouped about the region λλ 3900 A and 3100 A respectively The following table gives the separations which occur between the components of a few of the principal multiple terms For the purpose of comparison the corresponding separations in the analogous spectra of doubly ionised fluorine, chlorine, and bromine (already determined by previous investigators) have also been included in the table

Elements		F^{++}	Cl^{++}	Br^{++}	I^{++}
Atomic No		9	17	35	53
P in X_1 level	$P_1 - P_2$	211	358	518	576

Agricultural Field Experiments

IN the correspondence on this subject in NATURE of Nov 29 last, p 843, ' The Writer of the Article " suggests that depth of sowing in wheat plays an important part in accurate field experiments Many years' experience on the black cotton soils of Central India and on the alluvium of the Indo Gangetic plain fully confirms this view Until quite recently, the practice among the cultivators round Indore was to sow wheat by means of a bamboo tube fixed behind the country plough The consequence was that many of the seeds germinated but the seedlings never reached the surface In dry years particularly, when many of the seeds were covered by large clods, a very uneven stand was obtained Some years ago, a member of the staff of this Institute Mr K R Joshi, devoted a good deal of time to the study of this question, and found that much better and more even stands of wheat could be obtained by the two coulter Gujerati drill, which deposits the seed in the moist layer of soil just below the dry surface mulch The cultivators are now rapidly changing their practice, and the drilling of wheat is now to be seen in many of the villages on the Malwa plateau I have myself, on the alluvial soils of the plains often observed the deleterious effect of sowing wheat too far below the surface

In both plant breeding work on wheat and in variety trials too much attention cannot be paid to correct farming procedure It is obvious in such questions that nothing can be gained by the application of formulæ and figures to the results obtained by poor agriculture

Wisdom in Words

THE time may come

When the Gates cease to ruggle
When the Danes hald in juggle
And the Brides can write no more

that Lamarckian moonshine will no longer be adumbrated in terms of Hibernian green and questions as to the meaning of life will be discussed in language that has plain meaning Awaiting that far off day, we may ask What is the difference between a philosopher and a scientific man—can either, if there be two of them, be as such ' ? Mr Bartrum would treat them as beings apart The one term is Greek, the other Latin of sorts The one is a man who has and uses knowledge, maybe makes it The other is a lover of knowledge of wisdom but it is impossible to love without having and using and even seeking for an increase in return Seeing that it is the business of the scientific man *to know*, truth is his clear concern in his every search Faraday, *the scientific man* ' par excellence ' in history, ever the seeker after truth and wisdom definitely elected to call himself a *philosopher*, he also sought to use a clear language Surely our present need is to get rid of the flossofer ' *as such*— the mere man of words, who but thinks he knows

Is there more behind all this pother about evolution and vitalism —not to mention entelechy—than mere word slinging ? Have we not had more than enough of it to satisfy our present state of ignorance of intimate organic structure ? That we can see the chromosome is wonder enough Let us leave it at that, until we can put some real chemistry into its purse , all talk of ' autocatalysis ' is just meaningless, pretentious phrasing INQUIRER

Determination of the Velocities of Projectiles by Light Interception.

THE principle of the method for the determination of the velocity of projectiles described by Taylor and Wark in the issue of NATURE for Dec 27, p 994, has been used previously, notably by Kampé de Fériet, who published a full description, illustrated with some excellent photographs, in 1925 (*Mem de l'Art franc*, vol 4, p 289) Using what was essentially a single but comparatively wide band of light, a continuous record was obtained of the flight of the projectile for a distance of 25 metres

Consideration of the flight of solid projectiles has been helpful to us in our investigation of the solid particles sent out at high speed by coal mining explosives For this purpose, using our ' wave speed camera (Safety in Mines Research Board, *Paper* No 29, 1926), we have developed a method of recording photographically the movement of rifle bullets By this means we have obtained a continuous light interception record similar to those of Kampé de Fériet, but combined with a continuous *Schlieren* record of the atmospheric pressure waves and the powder gases, visible or invisible, sent out from the rifle

The results have been embodied in a paper which will be published at an early date

School Natural History Societies

IT has been brought to the notice of the Corresponding Societies Committee of the British Association that a number of noteworthy scientific and natural history societies exist in connexion with public schools of which the Committee would welcome brief particulars of their origin and development, together with an epitome of practical work attempted in their respective districts, especially where the observations have been published

It would be a valued assistance to my Committee if any readers of NATURE could conveniently furnish me with the names of societies of this kind known to them which, in their opinion, might be invited to contribute some particulars as to work accomplished to a report which it is proposed to prepare for the centenary meeting of the Association in September next CLARENCE TIERNEY

Synthesis of Munjisthin

A MISTAKE in nomenclature has, through our inadvertence, crept into our communication on the " Synthesis of Munjisthin , published in NATURE of Nov 15, 1930, page 761, which we hasten to rectify

In line 6 par 2, instead of "2 chloro 3 methyl 4 methoxy", read 1 chloro 2 methyl 3 methoxy" and in lines 8 9 of the same par , instead of " 2 chloro 3 methyl 4 hydroxy , read ' 1 chloro 2 methyl 3 oxy "

The mistake, which we very much regret, is due to our overlooking the fact that the position (2') in the formula of benzoyl benzoic acid becomes the position (1) in the formula of the anthraquinone

Present Status of Theory and Experiment as to Atomic Disintegration and Atomic Synthesis *

By Prof ROBERT A MILLIKAN, California Institute of Technology, Pasadena, California

MY task is to attempt to trace the history of the development of scientific evidence bearing on the question of the origin and destiny of the physical elements I shall list ten discoveries or developments, all made within the past hundred years, which touch in one way or another upon this problem and constitute indications or sign-posts on the road toward an answer

Prior to the middle of the nineteenth century, little experimental evidence of any sort had appeared, so that the problem was wholly in the hands of the philosopher and the theologian Then came, first, the discovery of the equivalence of heat and work, and the consequent formulation of the principle of the conservation of energy, probably the most far-reaching physical principle ever developed

Following this, and directly dependent upon it, came, second, the discovery, or formulation, of the second law of thermodynamics, which was first interpreted, and is still interpreted by some, as necessitating the ultimate 'heat-death' of the universe and the final extinction of activity of all sorts, for all hot bodies are observed to be radiating away their heat, and this heat after having been so radiated away into space apparently cannot be reclaimed by man This is classically and simply stated in the humpty-dumpty rhyme As a natural if not necessary corollary to this was put forward by some, in entire accord with the demands of medieval theology, a *Deus ex machina* initially to wind up or start off this running-down universe

Then came, third, the discovery, through studies both in geology and biology, of the facts of evolution—facts which showed that, so far as the biological field is concerned, the process of creation, or upbringing from lower to higher forms, has been continuously going on for millions upon millions of years and is presumably going on now This tended to direct attention away from the *Deus ex machina*, to identify the Creator with his universe, to strengthen the theological doctrine of immanence, which represents substantially the philosophic position of Leonardo da Vinci, Galileo, Newton, Francis Bacon, and most of the great minds of history down to Einstein

Neither evolution nor evolutionists have in general been atheistic—Darwin least of all—but their influence has undoubtedly been to raise doubts about the legitimacy of the dogma of the *Deus ex machina* and of the correlative one of the heat-death This last dogma rests squarely on the assumption that we, infinitesimal mites on a speck of a world, know all about how the universe behaves in all its parts, or more specifically, that the radiation laws which seem to us to hold here cannot possibly have any exceptions anywhere, even though that is precisely the sort of sweeping generalisation that has led us physicists into error half a dozen times during the past thirty years, and also though we know quite well that conditions prevail outside our planet which we cannot here duplicate or even approach Therefore the heat-death dogma has always been treated with reserve by the most thoughtful of scientific workers No more crisp or more cogent statement of what seems to me to be the correct position of science in this regard has come to my attention than is found in the following recent utterance of Gilbert N Lewis, namely, "Thermodynamics gives no support to the assumption that the universe is running down" "*Gain of entropy always means loss of information and nothing more*"

The fourth discovery bearing on our theme was the discovery that the dogma of the immutable elements was definitely wrong By the year 1900 the element radium had been isolated and the mean lifetime of its atoms found to be about two thousand years This meant definitely that the radium atoms that are here now have been formed within about that time, and a year or two later the element helium was definitely observed to be growing out of radium here and now This raised insistently the question as to whether the creation, or at least the formation, of all the elements out of something else may not be a continuous process—stupendous change in viewpoint the discovery of radioactivity brought about, and a wholesome lesson of modesty it taught to the physicist But a couple of years later, uranium and thorium, the heaviest known elements, were definitely caught in the act of begetting radium, and all the allied chain of disintegration products Since, however, the lifetime of the parent atom, uranium, has now been found to be a billion years or so, we have apparently ceased to inquire whence it comes We are disposed to assume, however, that it is not now being formed on earth Indeed, we have good reason to believe that the whole radioactive process is confined to a very few, very heavy elements which are now giving up the energy which was once stored up in them—we know not how—so that radioactivity, though it seemed at first to be pointing away from the heat death, has not at all, in the end, done so Indeed, it seems to be merely one mechanism by which stored-up energy is being frittered away into apparently unreclaimable radiant heat—another case of humpty dumpty

The fifth significant discovery was the enormous lifetime of the earth—partly through radioactivity itself, which assigns at least a billion and a half years—and the still greater lifetime of the sun and stars—thousands of times longer than the periods through which they could possibly exist as suns if they were simply hot bodies cooling off This meant that new and heretofore unknown sources of heat energy had to be found to keep the stars pouring out such enormous quantities of radiation for such ages upon ages

* Retiring presidential address to the American Association for the Advancement of Science, delivered at Cleveland on Dec 29

The sixth discovery, and in many ways the most important of all, was the development of evidence for the interconvertibility of mass and energy This came about in three ways In 1901 Kaufman showed experimentally that the mass of an electron could be increased by increasing sufficiently its velocity that is, energy could be definitely converted into mass About the same time the pressure of radiation was experimentally established by Nichols and Hull at Dartmouth College, New Hampshire, and Lebedew at Moscow This meant that radiation possesses the only distinguishing property of mass, the property by which we define it, namely, inertia The fundamental distinction between radiation and matter thus disappeared These were direct, experimental discoveries Next, in 1905, Einstein developed the interconvertibility of mass and energy as a necessary consequence of the special theory of relativity If, then, the mass of the sun could in any way be converted into radiant heat, there would be an abundant source of energy to keep the sun going so long as necessary, and all our difficulties about the lifetimes of the sun and stars would have disappeared But what could be the mechanism of this transformation ?

Then came the seventh discovery, which constituted a very clear finger post, pointing to the possibility of the existence of an integrating or building-up process among the physical elements, as well as in biological forms, in the discovery that the elements are all definitely built up out of hydrogen , for they—the ninety-two different atoms—were all found, beginning about 1913 by the new method of so-called positive ray analysis, to be exact multiples of the weight of hydrogen within very small limits of uncertainty This fact alone raises very insistently the query as to whether they are not being built up somewhere out of hydrogen now They certainly were once so put together, and some of them, the radioactive ones, are now actually caught in the act of splitting up Is it not highly probable, so would say any observer, that the inverse process is going on somewhere, especially since the process would involve no violation either of the energy principle or of the second law of thermodynamics, for hydrogen, the element out of which they all must be built, has not a weight exactly one in terms of the other ninety-two, but about 1 per cent more than one, so that since mass or weight had been found in the sixth discovery to be expressible in terms of energy, the union of any number of hydrogen atoms into any heavier element, meant that 1 per cent of the total available potential energy had disappeared and was therefore available for appearance as heat

When, about 1914–15, this fact was fitted by MacMillan, Harkins, and others into the demand made above in the fifth discovery for a new source of energy to keep the sun pouring out heat so copiously for such great lengths of time, it seemed to the whole world of physics that the building up of the heavier elements out of hydrogen under the conditions existing within the sun and stars had been practically definitely proved to be taking place This would not provide an escape from the heat-death, but it would enormously postpone it, that is, until all the hydrogen in the universe had been converted into the heavier elements

By this process, however, the suns could stoke at most but 1 per cent of their total mass, assuming they were wholly hydrogen to begin with, into their furnaces, and 99 per cent of the mass of the universe would remain as cold, dead ash when the fires were all gone out and the heat-death had come But about 1917 the astronomer began to chafe under the time-limitation thus imposed upon him, and this introduced the eighth consideration bearing upon our theme He could get a hundred times more time—from now on, much more than that, because only a small fraction of the matter in the universe is presumably now hydrogen—by assuming that, in the interior of heavy atoms, occasionally a negative electron gets tired of life at the pace it has to be lived in the electron world, and decides to end it all and commit suicide , but, being paired by Nature in electron-fate with a positive, he has to arrange a suicide pact with his mate, and so the two jump into each other's arms in the nucleus, and the two complementary electron lives are snuffed out at once , but not without the letting loose of a terrific death-yell, for the total mass of the two must be transformed into a powerful ether pulse which, by being absorbed in the surrounding matter, is supposed to keep up the mad, hot pace in the interiors of the suns This discovery, or suggestion, to account for the huge estimated stellar lifetimes, of the complete annihilation of positive and negative electrons within the nucleus, makes it unnecessary to assume, at least for stellar lifetime purposes, the building up of the heavier elements out of hydrogen Indeed, it seems rather unlikely that both kinds of processes, atom building and atom annihilating, are going on together in the same spot under the same conditions , so we must turn to further experimental facts to get more light

The ninth sign-post came into sight in 1927, when Aston made a most precise series of measurements on the relative masses of the atoms, which made it possible to subject to a new test the Einstein formula for the relation between mass and energy, namely, $E = Mc^2$ This Aston curve is one of the most illuminating finger-pointings we now have It shows that

1 Einstein's equation actually stands the quantitative test for radioactive or disintegrating processes right well, and therefore receives new experimental credentials

2 The radioactive or disintegrating process with the emission of an alpha ray must be confined to a very few heavy elements, since these are the only ones so situated on the curve that mass can disappear, and hence heat energy appear, through such disintegration

3 All the most common elements, except hydrogen, are already in their most stable condition, that is, their condition of minimum mass, so that if we disintegrate them we shall have to do work upon them, rather than get energy out of them

4 Therefore, man's only possible source of

energy other than the sun is the upbuilding of the common elements out of hydrogen or helium, or else the entire annihilation of positive and negative electrons, and there is no likelihood that either of these processes is a possibility on earth

5 If the foregoing upbuilding process is going on anywhere, the least penetrating and the most abundant radiation produced by it, that corresponding to the formation of helium out of hydrogen, ought to be about ten times as energetic as the hardest gamma rays, that is, it ought to correspond to about twenty-six million electron-volts in place of two and a half million

6 Other radiations corresponding to the only other abundant elements, namely, oxygen (oxygen, nitrogen, carbon), silicon (magnesium, aluminium, silicon), and iron (iron group), should be found about four times, seven times, and fourteen times as energetic as the 'helium rays'

7 The radiation corresponding to the smallest annihilation process that can take place—the suicide of a positive and negative electron—is three hundred and fifty times as energetic as the hardest gamma ray, or thirty-five times as energetic as the 'helium ray'

This brings us to the tenth discovery, that of the cosmic rays These reveal *

1 A radiation, the chief component of which, according to our direct comparison, is five times as penetrating as the hardest gamma ray, which, with the best theoretical formula we have relating energy and penetrating power (Klein-Nishina), means a ray ten times as energetic as the hardest gamma ray, *precisely according to prediction*

2 Special bands of cosmic radiation that are roughly where they should be to be due to the formation of the foregoing abundant elements out of hydrogen, though (for reasons to be given presently) no precise quantitative check is to expected except in the case of helium

3 No radiation of significant amount anywhere near where it is to be expected from the annihilation hypothesis, thus indicating that at least 95 per cent of the observed cosmic rays are due to some other less energetic processes

4 A radiation that is completely independent of the sun, the great hot mass just off our bows, and not appreciably dependent on the Milky Way or the nearest spiral nebula, Andromeda, one that comes in to us practically uniformly from all portions of the celestial dome, and is so invariable with both time and latitude at a given elevation that the observed small fluctuations at a given station reflect with much fidelity merely the changes in the thickness of the absorbing air blanket through which the rays have had to pass to get to the observer

This last property is the most amazing and the most significant property exhibited by the cosmic rays, and before drawing the final conclusions its significance will be discussed For it means that at the time these rays enter the earth's atmosphere, they are practically pure ether waves or photons

* See articles by Millikan and by Millikan and Cameron, *Phys Rev*, Dec 1, 1930, and in press

If they were high-speed electrons or even had been appreciably transformed by Compton encounters in passing through matter into such high-speed electrons or beta rays, these electrons would of necessity spiral about the lines of force of the earth's magnetic field and thus enter the earth more abundantly near the earth's magnetic poles than in lower latitudes This is precisely what the experiments made during the last summer at Churchill, Manitoba (lat 59° N), within 730 miles of the north magnetic pole, showed to be *not true*, the mean intensity of the rays there being not measurably different from that at Pasadena in lat 34° N

Nor is the conclusion that the cosmic rays enter the earth's atmosphere as a practically pure photon beam dependent upon these measurements of last summer alone It follows also from the high altitude sounding balloon experiments of Millikan and Bowen in April 1922, taken in connexion with the lower balloon flights of Hess and Kolhorster in 1911-14 For in going to an altitude of 15 5 km we got but one fourth the total discharge of our electroscope which we computed we should have obtained from the extrapolation of our predecessors' curves This shows that somewhere in the atmosphere below a height of 15 5 km the intensity of the ionisation within a closed vessel exposed to the rays goes through a maximum, and then decreases, quite rapidly, too, in going to greater heights We have just taken very accurate observations up to the elevation of the top of Pike's Peak (4 3 km), and found that within this range the rate of increase with altitude is quite as large as that found in the Hess and Kolhorster balloon flights, so that there can be no uncertainty at all about the existence of this maximum Such a maximum, however, means that the rays, before entering the atmosphere, have not passed through enough matter to begin to get into equilibrium with their secondaries—beta rays and photons of reduced frequency—in other words, *that they have not come through an appreciable amount of matter in getting from their place of origin to the earth*

This checks with the lack of effect of the earth's *magnetic field* on the intensity of the rays, and the two phenomena, of quite unrelated kinds and brought to light years apart, when taken together, prove most conclusively, I think, that the cosmic rays cannot originate even in the outer atmospheres of the stars, though these are full of hydrogen and helium in a high temperature state, but that they must originate rather in those portions of the universe from which they can come to the earth without traversing matter in quantity that is appreciable even as compared with the thickness of the earth's atmosphere—in other words, that *they must originate in the intensely cold regions in the depths of interstellar space*

Further, the more penetrating the beta rays produced by Compton encounters, the greater the thickness of matter that must be traversed before the beam of pure photons which enters the atmosphere gets into equilibrium with its secondaries, and until such equilibrium is reached, the apparent

absorption coefficient must be less than the coefficient computed with the aid of the Klein-Nishina formula from the energy released in the process from which the radiation arises. Now the Bothe Kolhorster experiments of about a year ago show that when the energies of the incident photons are sufficiently high, the beta rays released by Compton encounters do indeed become abnormally penetrating, so that it is to be expected that, for the cosmic rays produced by the formation of the heavier of the common elements like silicon and iron out of hydrogen, the observed absorption coefficients will be somewhat smaller than those computed from the energy available for their formation. This is precisely the behaviour which our cosmic ray depth-ionisation curve actually reveals. At the highest altitudes at which we have recently observed (14,000 ft.), the helium rays have reached equilibrium with their secondaries, and the observed and computed coefficients agree as they should. For the oxygen rays the observed coefficent is a little lower than the computed value—about 17 per cent lower; for the silicon rays still lower—about 30 per cent; and for the iron rays considerably lower still—about 60 per cent; all in beautiful qualitative agreement with the theoretical demands as outlined.

The foregoing results seem to point with much definiteness to the following conclusions:

1. The cosmic rays have their origin not in the stars but rather in interstellar space.

2. They are due to the building up in the depths of space of the commoner heavy elements out of hydrogen, which the spectroscopy of the heavens shows to be widely distributed through space. That helium and the common elements oxygen, nitrogen, carbon, and even sulphur, are also found between the stars is proved by Bowen's beautiful recent discovery that the 'nebulium lines' arise from these very elements.

3. These atom-building processes cannot take place under the conditions of temperature and pressure existing in the sun and stars, the heats of these bodies having to be maintained presumably by the atom-annihilating process postulated by Jeans and Eddington as taking place there.

4. All this says nothing at all about the second law of thermodynamics or the *Wärme-Tod*, but it does contain a bare suggestion that if atom formation out of hydrogen is taking place all through space, as it seems to be doing, it may be that the hydrogen is somehow being replenished there, too, from the only form of energy that we know to be all the time leaking out from the stars to interstellar space, namely, radiant energy. This has been speculatively suggested many times before, in order to allow the Creator to be continually on his job. Here is, perhaps, a little bit of *experimental* finger-pointing in that direction. But it is not at all proved or even perhaps necessarily suggested. If Sir James Jeans prefers to hold one view and I another on this question, no one can say us nay. The one thing of which we may all be quite sure is that neither of us *knows* anything about it. But for the continuous building up of the common elements out of hydrogen in the depths of interstellar space the cosmic rays furnish excellent experimental evidence. I am not unaware of the difficulties of finding an altogether satisfactory kinetic picture of how these events take place, but acceptable and demonstrable facts do not, in this twentieth century, seem to be disposed to wait on suitable mechanical pictures. Indeed, has not modern physics thrown the purely mechanistic view of the universe root and branch out of its house?

Geodesy in India

IN the British Empire at the present time, geodetic operations are mainly confined to Canada, India, and South Africa. The Dominion and the Union are working principally for the more pressing needs of development; in India, on the other hand, apart from the necessity for revision, more attention is being paid to the interpretation of results. The Great Trigonometrical Survey of India itself being long complete, triangulation is now being carried on in the outer zones—in Burma and on the Siamese frontier at the date of the last Geodetic Report.[1]

The main triangulation in 1928-29 was executed with Wild theodolites, which gave very good results when the instruments were working. Their axes, however, stiffened in the field, causing serious loss of time. Surveyors cannot adjust the instruments in the field, and even the mathematical instrument workshop in Calcutta found adjustment difficult, though mere oiling is simple if the method is known. It was intended to keep the older and heavier 12-inch theodolites at hand during the ensuing season, in case of further failures.

Precise levelling is perhaps the most economically important section of the revisionary geodetic work: of the new net of 16,000 miles proposed, nearly one half was completed in 1929. Levelling on hilly circuits appears to show that the shorter sights thereon contribute to accuracy as against longer sights in flat country; experience in precise levelling has given revised results on hilly circuits in Ceylon which are practically as good as on the plains. Indian investigations show that error due to differential refraction on steep slopes is negligible, and the greater part of the errors of closure is believed to be due to changing length of the staves. The results of levelling must lie within limits of accidental and systematic error which are strictly defined; one notices that 55 per cent of one line was relevelled. On the several lines—not yet, of course, referred strictly to M.S.L.—the relative discrepancies between the new and the old measures do not ordinarily exceed 6 inches; but there are interesting exceptions. Thus there is evidence of a sinkage around Ambala of about an inch per decade, attributed to removal of water from wells. On the line between Sukkur and Hyderabad the results of much levelling have given

measures so discordant that it has been decided to abandon the line India has hitherto used wooden staves, and it is not stated if these have been rendered non-hygroscopic, change in length, which appears to have a diurnal range, being attributed to temperature In any event, staves with invar strips were to be substituted

Heights are subject to orthometric and dynamic corrections, the former to take account of the non-parallelism of the equipotential surfaces at different altitudes, the latter to refer all heights to a standard equipotential surface of sea-level at a mean latitude, in India 24° north The corrections are easily computed by formulæ, in which case they depend on theoretical, not observed, values of gravity The Director of the Geodetic Branch, Dr De Graaf Hunter, discusses the question of a rigorous investigation, and finds that the effect at Mussoorie, 7000 feet, is 0 7 ft, he concludes that the severe labour involved in applying a rigorous correction is not justifiable in hilly country and is unnecessary in flat country, even though in strictness values derived by formula give heights in an unknown unit above an unknown datum

India controls tide-gauges at forty eastern ports and issues predictions An outstanding discrepancy in 1928 was 4 6 feet at Basrah on a certain date—not surprising at the mouth of great rivers and at the head of a great gulf By arrangement with the Admiralty, the tide-tables will be extended to sixty-eight ports in the Indian Ocean, and they will be issued in cheaper form—sufficient evidence of the success of the Survey in deriving harmonic constants in a region where monsoons and unique tides must sometimes give rise to peculiar conditions

It has been decided to re-map at least a portion of the Dependency on areas of conical orthomorphic projection, in such an immense area the change over will be gradual The areas proposed are 8° in latitude by 16° in longitude In this matter South Africa and India represent extreme views, the former adopting a width of 2° as against 8° in India At the bounding parallels the scale error is about 1/400, which will be reduced one-half by a scale factor The magnitude of the scale error and, perhaps more particularly, the rapid change of scale at the bounding parallels will doubtless evoke criticism

The Survey has constructed a mural base for standards of length Such bases already exist at Sèvres and Teddington, yet the writer doubts if this is the best form of construction, even though the thermal expansion of the wall becomes fairly well known after some years

In the course of the longitude campaign the variation of latitude was studied, the results appear to show a well-marked correlation with the moon's age, as already described in NATURE [2] The mean longitude of Dehra Dûn as derived from the Bordeaux and Rugby signals in 1928–29 is 5 h 12 m 11 79 s, precisely the same as in the longitude campaign of 1926 A Shortt clock was installed this year to supplement the Riefler

The most interesting portions of the Report deal with gravity and the geoid in India, it would be impossible to deal adequately in a short review with the wealth of material here provided The Director reaffirms his conclusion that conditions of approximately perfect Hayford isostasy are not met with in peninsular India, but the interested reader must be referred to the Report itself for a description of the numerous investigations Work with the Cambridge pendulum apparatus is being vigorously pursued, old values being revised and new stations added, with the object of having one station in every seventy mile square

The Survey of India has made remarkable contributions to geodesy in the past It is doubtful if any single volume has approached in interest and instruction that of the year under review

Obituary

THE death on Dec 28 of Prof Eugen Goldstein, head of the Astro-Physical Section of the Potsdam Observatory, removes an observer whose work on the phenomena which accompany the passage of electricity through rarefied gases is well known He was born at Gleiwitz on Sept 5, 1850, was educated at the Ratibor Gymnasium and the Universities of Breslau and Berlin At Berlin he worked under Helmholtz at the electric discharge in vacuum tubes, and in 1876 his first paper on the subject appeared in the *Berliner Berichte*, and was followed for fifty years by a long series dealing with cathode and anode rays and the influence of magnetic fields and of the dimensions of the discharge tube on the character of the discharge He maintained throughout that the luminous discs of the positive column were repetitions with decreased intensity of the cathode glow His recent work was mainly on the complex discharge near the anode, but he is probably best known for his discovery of the anode or canal rays He was awarded the Hughes Medal by the Royal Society in 1908

WE regret to announce the following deaths

Mr R G Lunnon, lecturer in physics at Armstrong College, Newcastle

Dr A P Maudslay, president in 1911–12 of the Royal Anthropological Institute, who was well known for his investigations of Mayan and Aztec sites in Mexico and Central America, on Jan 22, aged eighty-one years

Mr H W Monckton, sometime treasurer and several times vice president of the Geological Society, and vice president and treasurer of the Linnean Society up to the time of his death, on Jan 14, aged seventy-four years

Prof C Y Wang, professor of pathology in the University of Hong Kong, author of numerous papers on tuberculosis and other bacterial diseases, on Dec 16, aged forty two years

News and Views.

AT a recent meeting of the Council of the University of Bristol, an announcement was received with much gratification of two munificent offers for the endowment of research in physics, one from the Rockefeller Foundation and one from Mr W Melville Wills Impressed by the possibilities of the Henry Herbert Wills Physical Laboratory as a centre of research, the Rockefeller Foundation offered the sum of £50,000 to the University of Bristol for the endowment of research in experimental and theoretical physics, on condition that a further contribution of £25,000 for the same purpose was secured from other sources Mr Melville Wills, already a benefactor to the University, has most generously offered to give the required sum of £25,000 in memory of his late brother, the founder of the laboratory Thanks to this further act of beneficence by a member of the Wills family, the University has been able to accept the Rockefeller Foundation's offer The laboratory was founded by a gift of £200,000 from the late Mr Henry Herbert Wills, and was opened in 1927 under the direction of Prof A M Tyndall A broad view of the term 'laboratory' was taken, and a professorship in theoretical physics was created so that the closest co operation between theory and experiment might be effected in the laboratory With the concurrence of the Rockefeller Foundation, the gift of Mr Melville Wills will be utilised for the endowment of the chair at present held by Prof J E Lennard Jones in theoretical physics One portion of the Rockefeller gift will be devoted to researches in the field of molecular structure and the borderland of physics and chemistry, to which the laboratory has already contributed on both the theoretical and the experimental sides After providing for certain other immediate needs, the remainder of the gift will form a reserve to meet the growing requirements of the laboratory as a centre of research

ON Feb 5 occurs the centenary of the death of Commander Henry Foster who in 1827 was awarded the Copley Medal of the Royal Society for his magnetic observations made in the Arctic regions Born in August 1796, Foster was the eldest son of a clergyman of Woodplumpton, near Preston, Lancs, and joined the Navy as a volunteer in 1812 He served in various parts, and after the Napoleonic wars became known as a surveyor He accompanied Basil Hall to South America in 1820, served under Parry in the *Hecla* in 1824 and in 1827, and it was for his work in the *Hecla* that he was awarded the Copley Medal Promoted to commander, he was appointed to the command of the *Chanticleer*, commissioned by the Admiralty, at the request of the Royal Society, for determining the ellipticity of the earth Foster sailed in April 1828, visiting South America and the Cape and then Panama, where he unfortunately met his death by accidental drowning in the River Chagres His body was recovered and a monument was erected over his grave There is also a tablet to his memory in Woodplumpton Church Foster's pendulum experiments, carried out at fourteen different stations between 10° 38′ north latitude and 62° 56′ south latitude, were made with the most scrupulous regard to accuracy, and they were the most extensive series of experiments made up to that time After his death his papers were placed in the hands of Baily, who gave an account of his work in the seventh volume of the *Memoirs* of the Royal Astronomical Society

"BIOLOGY and Statecraft" formed the subject of a national lecture broadcast by Sir Walter Morley Fletcher on Jan 23 Sir Walter briefly epitomised the historical developments in biology, and emphasised the sudden speeding up of this development within the memory of living man Reasons were given for this sudden increase in speed of development, the chief two being the invention of the microscope and the use of experiment The latter, we think, forms the most important explanation of all Microscopy has just followed a serene type of development since its inception in the seventeenth century On the other hand, experimental biology, such as physiology, and the chemical aspects of mycology, entomology, and so on, are of much more recent development It was entomology, a comparatively recent science, that received Sir Walter's attention, based on his statement that insects are still our most destructive enemies and rivals Such insects will have to fight hard with pathological bacteria in order to retain this distinction As Sir Walter pointed out, the study of entomology should receive more recognition by the State There are only 275 official entomologists in the British Empire, and we spend only a quarter of the amount that the United States of America spend on this science It is difficult to ascribe this dearth of entomologists to any one factor We must not blame completely, as Sir Walter suggests, the lacking in scientific knowledge by our statesmen and those in administrative authority, for they are now offering great facilities for the training of entomologists, but, we believe, the root of the trouble is that such opportunities for training, offered by the State, have not yet been appreciated by men students Nevertheless, as we have often remarked, science must not become the tool of the State, but must always remain the concern of the State, and then, as Sir Walter said of biology, we shall be able to bring into our methods of statecraft the guidance of biological truth

THE Representation of the People Bill, which has recently been issued, includes a clause providing for the total abolition of university constituencies These constituencies were originated at the beginning of the seventeenth century by James I with the object of enabling universities to send grave and learned representatives to parliament As, however, men of scholarship are not now segregated and confined solely to universities, these constituencies were threatened with extinction just before the War, though, since then, as stated in a leading article in NATURE of Nov 4, 1922, they have become enhanced in prestige and extended application It is on this

latter observation that the case for the retention of university constituencies should be based At the same time, some type of legislative reform is clearly necessary, if only to take account of modern developments of universities In view of this progress, the present method of university representation is distinctly old-fashioned and undesirable Plural representation of the older universities seems unnecessary, and a fuller representation of the newer universities is worthy of consideration The list of voters in 1929, which appears in the memorandum upon university representation submitted to the electors of the older universities, the substance of which appears on p 183, supports this view However this may be, the proposal to abolish university constituencies altogether must raise strong protests from members of all parties

THE university of to day is not merely a collection of books as Carlyle suggested, neither is it just a place of advanced lectures followed by examinations and ultimately a degree At one time, it was, but now it is the head of, the power behind, the whole of our great system of education, without putting itself as the 'be all and end all' of everyone who is being educated In more ways than one it influences all primary and secondary education, and has thus become a great, comprehensive entity Although we have a Board of Education with its specially appointed advisory councils and committees, representatives of universities—that is, representatives of our complete educational system, from five to twenty five—are clearly desirable in Parliament, to safeguard and advertise the aims and projects of one of the most essential features of our modern constitution It is therefore a little surprising that a measure to abolish direct academic representation should be brought forward at the present time, and especially by a government which has shown genuine concern for the development of educational work of all types

ALTHOUGH we have as yet in the British Isles no professedly and distinctively Children's Museum on the lines of the many now existing in the United States, still the movement here is progressing Indeed, under the curatorship of Miss Beatrice Hindshaw, the Horsfall Art Museum in Ancoats, Manchester, is already in practice, if not in theory, a museum for the boys and girls of that otherwise poor district In the Liverpool Museum, Dr Allan has been furnishing a Children's Corner, and the boys, if not the girls also, of London are eagerly awaiting the treat promised them by Sir Henry Lyons at the Science Museum These are notable instances of what is being done, but the museum founded for children alone is yet unborn It is, however, in embryo A meeting held in London a few months ago decided "to found a Children's Museum in London, to be a national and international centre, to educate and inspire the children of all races, and to stimulate child-lovers of the British Empire and the World"

To judge from the printed statement, the promoters of the Children's Museum base their museum idea on the child's world as it appears to the child, or as it might more happily appear, rather than on the world of the adult, to which the museum should gently introduce the child Stress seems to be laid on such objects as toys, pictures, and models, and on such methods as marionettes, a children's orchestra, theatre, dance hall, and fairy tale rooms More serious subjects are not definitely excluded, but science and natural history might well bulk more largely in the programme These schemes, however, have a habit of growing according to circumstances rather than plan The important thing is to make a start in a house (or room) with some energetic curators (or even one only), and the gifts for which the distinguished supporters appeal will then flow in The honorary temporary secretary is Mrs Chas E Dawson, 8 Queen's Gardens, Lancaster Gate, London, W 2

AT a meeting of the Ross Institute Industrial Anti Malarial Advisory Committee in December last, reports were received on anti malarial work carried out in various tropical countries Dr G C Ramsay stated that in tea gardens in Assam he had been able to exclude hookworm disease and kala azar as chief sources of sickness among the coolies The principal cause of sickness, inefficiency, and death was malaria, and the contrast between the malarial and the non malarial gardens was extraordinary Mosquito control consisted, in the first place, in studying those species in a district which carried malaria, and their habits, and then taking measures directed especially against those species In his own district, Dr Ramsay found twenty species of anopheline mosquitoes present, but an intensive study proved that practically only one (*A minimus*) carried infection The value and application of larvicides, oiling, and Paris green as anti mosquito agents were described, and examples given of immediate improvement following their use Biological methods were also employed, such as encouraging the growth of certain swamp plants and destroying others Sir Malcolm Watson, principal of the Malaria Department, Ross Institute, confirmed Dr Ramsay's results He stressed the value of quinine in the treatment of malaria, provided it was used in sufficient doses over a sufficient period Plasmoquine might be a valuable adjunct to quinine, for it was claimed that this drug killed the sexual forms of the malaria parasite, which are those that infect the mosquito He pointed out that investigation is required to explain why some anopheline mosquitoes carry malaria and others do not, and why a particular species may carry malaria in one country and not in another

MR NICOLAUS, of the Selection Trust, speaking of the Rhodesian Copper Mines, stated that since the Ross Institute expedition to Northern Rhodesia the incidence of malaria at one mine had dropped from 27 per cent of population per month to only 8 cases per month in a population of between 8000 and 9000 At another mine, with a population of between 10,000 and 11,000, since mosquito control had been inaugurated, the malaria incidence last October was nine new cases only The Tata Iron and Steel Company have also adopted a scheme of mosquito control,

drawn up by Sir Malcolm Watson, and report that the Noamundi Mine is now entirely free from both larval and adult anophelines, and that no new cases of malaria have occurred for some time The Burma Shell Group is to join with the Ross Institute in an investigation of the oils available in India for oiling mosquito-breeding waters, so that the oil most suitable for any place in cold or in hot weather may be selected The Ross Institute Industrial Anti-Malarial Advisory Committee was formed in 1928 to keep industry in touch with science, to make the tropics healthy, and expand the markets of the world It consists of representative members of industry and members of the Ross Institute The Ross Institute and Hospital for Tropical Diseases, Putney Heath, London, S W 15, is entirely supported by voluntary contributions

THE annual general meeting of the Royal Meteorological Society was held on Jan 21, when Mr R G K Lempfert was re elected president The Buchan Prize, which is awarded biennially for the most important original papers contributed to the Society during the previous five years, was presented to Dr C E P Brooks Mr R G K Lempfert delivered an address on the work of the Meteorological Office at the Royal Airship Works, Cardington, of which Mr M A Giblett, who lost his life in the disaster to the *R101*, was in charge The weather charts constructed from all available material for the study of the conditions over the area between Great Britain and India were described The greater part of the address was, however, devoted to describing the experimental investigation of atmospheric turbulence which is still in progress Four anemometer stations have been set up at Cardington, separated from one another by distances of about 700 feet Each station is equipped for recording the direction and velocity of the wind on a very open time scale, so that the variations of wind from second to second can be examined Comparison of these detailed records from the four stations will furnish important information regarding the extent and intensity of the eddies which are always present in the wind The importance of the eddying character of the air movement which we call wind is being more and more recognised in the science of meteorology The stresses and strains to which structures are exposed during gales are due to the eddies Fog formation equally depends on eddy motion, though on a different scale, so does the distribution of atmospheric pollution Closely associated with the details of wind structure is the distribution of temperature in the vertical, and the arrangements made at Cardington, and also at Ismailia, for keeping this important meteorological factor under constant observation up to a level of 200 feet were described

AN important feature of the work of the enlarged Rubber Service Laboratory of Imperial Chemical Industries, Ltd , opened at Blackley on Jan 22, is that devoted to rubber service for users of Vulcafor products, and is intended to assist rubber manufacturers in the solution of problems which arise in connexion with the use of accelerators, anti-agers, pigments, and other products; but research work represents one of its chief activities Such research work includes studies on the new rubber substitutes, etc , prepared by the treatment, polymerisation, and so forth, of vegetable oils and other organic compounds, with the object of developing new products for use in the rubber industry, also investigations aiming at the discovery of vulcanisation accelerators, anti-agers or anti oxidants, anti-scorching compounds, etc , of improved properties, intended to increase the life of rubber articles During the last few years, for example, the mileage life of a motor tyre has been increased from the order of 5000 to nearly 20,000 Other research is concerned with the properties of various rubber compounds and the development of improved methods of physical and chemical testing The laboratory is a normal development of the British dyestuffs industry, with the other research laboratories of which it is in close collaboration The enlarged laboratory is the most completely equipped of its type outside the United States of America

IN one of his series of popular meteorological articles entitled "Why the Weather", issued by Science Service, Washington, D C , Prof C F Talman directs attention to important advances in travelling comfort introduced in recent years in the United States On certain steamers that navigate tropical waters, and later on certain railway lines crossing very hot desert regions, arrangements for controlling the temperature and humidity of the air in saloons and restaurants have been successfully introduced Experiments on these lines must lead to increased knowledge of the effect of various atmospheric conditions on human comfort, and it is to be hoped that they will result eventually in the carrying out of an important climatological inquiry A vast amount of information has been accumulated about the temperature, humidity, wind, etc , in different parts of the world, but anyone confronted with statistics of this kind is apt to be misled as to the extent to which any very abnormal temperatures are likely to give rise to discomfort, through inability to make a proper allowance for the other factors What is required is some system of reducing ordinary air temperatures to what might be called 'virtual temperatures', so that the regions of greatest physiological heat and cold could be shown on climatological maps It is recognised that the 'wet bulb' thermometer is superior to the ordinary 'dry bulb' in this respect, but something more representative of human sensations than even the wet bulb is required There is, for example, the difference of sensation between cloudy and clear weather, due to radiation effects, that should be taken into account Meteorological statistics would clearly be rendered of very much greater practical value if work on these lines could be successfully carried out on a world-wide scale

SIR WILLIAM BRAGG's Friday evening discourse on Jan 23, at the Royal Institution, on "The Scattering of Light", was the first to be given in the reconstructed theatre of the Royal Institution The subject of Sir William Bragg's discourse had a historical connexion with the Institution In its earliest form it asked

for explanations of the blue of the sky and sea Prof Tyndall and the late Lord Rayleigh were among the earliest and most important contributors to the solution of the problem Rayleigh put the theory on a sound basis, and explained exactly why the blue is scattered more than the red, so that it was turned aside while the red passed on The same explanation was applicable to the colours of the rising and setting sun Rayleigh showed also that there was no need to postulate the presence of water vapour the molecules of the air itself were sufficient to explain the amount of the scattering In recent years the interest of the subject has been greatly increased by the discoveries of Sir C V Raman, of Calcutta He has shown that there is a form of scattering hitherto not observed Some of the original light is scattered with change of colour, and this change is capable of the most precise measurement Many workers in various parts of the world have extended Raman's discovery and a new and most fascinating field of research has been opened up The change mentioned depends on the nature of the scattering atoms and molecules, the properties of which are thereby made capable of closer observation Moreover, the explanations of the new effects are more easily expressed in terms of the quantum or corpuscular theory of light, and in this way the highly attractive mystery of the nature of light is still further enhanced

THE Annual Report of the Director of the U S Bureau of Standards (Dr G K Burgess) to the Secretary of Commerce for the year ending June 30, 1930, is a pamphlet of 53 pages which gives a short account of each section of the work of the Bureau The staff numbers 1161, the average salary is £490, and the total expenses for the year £588,000, an increase of £37,000 on last year The largest item, £54,000, is for tests of building materials, the next, £44,000, for standardisation of the products of industry, and this work seems so much appreciated by the manufacturers that between 80 and 90 per cent of them are carrying out the recommendations of the Bureau in respect of between seventy and eighty commodities Industrial research has cost the Bureau £41,000, but forty-one associations and manufacturers co operate with the Bureau and maintain ninety six research associates, eleven of whom work at the Bureau on radio and electrical problems, eight on cements, eight on petroleum and its products, seven on fuel, and seven on steam and high temperatures The fee value of the tests carried out at the Bureau was £137,000 The present buildings are greatly over crowded and a five year building plan has been submitted to Congress

SOME interesting particulars of the activities of the Bureau of American Ethnology are given in the recently issued forty-fifth Annual Report, which covers the period 1927–28 Miss Densmore has made additional studies of the music of the American Indian, both in the field and in the laboratory Her remarkable collection of phonograph records now amounts to 1695 Study of the Columbia Basin and Lower Snake River in Oregon by Mr N W Kreiger has revealed a uniform culture, with some remarkably clearly defined localised specialisations in tools and art designs It is expected that further investigation will show the relation between the culture of this area and the pre agricultural south west In two areas in particular the work of the staff of the Bureau requires mention In the south western States the investigation of the Basket maker and Pueblo cultures is producing some of the most notable results in American archæology In Alaska, Mr Henry B Collings, jun , and Mr T Dale Stewart, conducting investigations at Nunivak Island and along the adjacent coast, have found what is held to be the most primitive of all the Alaskan Eskimo Among the "Accompanying Papers" two important contributions, dealing respectively with the Salishan tribes of the Western Plateaux and the Thompson Indians, are edited by Prof Boas from the papers of Mr James Teit, whose intimate knowledge of the Thompson Indians was based on a residence among them of many years It is interesting to note that Dr La Flèsche's record of an Osage war ritual was written down at the request of the Indians themselves to ensure correct rendering of the ritual at the next performance The request is significant as indicating a desire to keep up old customs, which is losing ground in a struggle against the weakening of tribal memory

THE Department of Zoology of the British Museum (Natural History) has recently received, as a donation from His Royal Highness the Duke of Gloucester, the skin and skull of a Menelik's bushbuck (*Tragelaphus scriptus meneliki*), and from Mr A S Vernay, a large collection of antelopes and other big game from Bechuanaland Recent donations from the Trustees of the Rowland Ward Bequest include a ratel, or 'honey badger' (*Mellivora ratel*), from Kenya Colony The ratel is found over a great part of Africa south of the desert region and in many parts of India The fore-limbs carry very large and powerful claws, which are used by the animal for burrowing Although a comparatively common animal, it is, owing to its nocturnal habits, but rarely met with, living amongst rocks or the roots of trees Ratels are practically omnivorous, feeding on honey, a variety of fruits, snakes, and sometimes raiding poultry farms They can attack bees' nests with impunity, as the great thickness of the skin prevents any serious harm being done by the bees' stings The Museum has also received a collection of more than 7000 specimens of land shells from Lord Howe Island and Norfolk Island , the land snails of these isolated islands are of importance for the study of geographical distribution, The Department of Botany has purchased the *Transactions* (in manuscript) of the Society of Amateur Botanists, in two volumes, 1863–64, from the library of Sir George Watt The Society was formed among the old students of M C Cooke's evening classes in botany, for artisans, held at Trinity Schools, Lambeth, where Cooke was head master Many others joined who afterwards became eminent botanists, including J Britten, W Thiselton Dyer, Berthold Seeman, Worthington G Smith, and Henry Trimen The meetings were held first same

Metropolitan Club Edgware Road, and then over Robert Hardwicke's shop in Piccadilly Hardwicke's *Science Gossip* was one result, another was the formation of the Quekett Microscopical Club, which replaced the Society in 1865

SIR WILLIAM BRAGG, Fullerian professor of chemistry in the Royal Institution, has been elected an honorary member of the Institution of Electrical Engineers

IT is announced in *Science* that Dr David White, senior geologist of the U S Geological Survey and home secretary of the National Academy of Sciences, was awarded the Penrose Medal at the Toronto meeting of the Society of Economic Geologists

THE one thousand dollar award of the American Association for the Advancement of Science for an outstanding paper presented at the recent Cleveland meeting was given to Drs M A Tuve, L R Hafstad, and O Dahl, of the Department of Terrestrial Magnetism of the Carnegie Institution of Washington Their paper entitled "Experiments with High Voltage Tubes" was presented to the American Physical Society

THE Society for Cultural Relations with Soviet Russia is considering the possibility of organising a tour of scientific institutes in Soviet Russia during July and August 1931 It is proposed to arrange for parties of British scientific workers engaged in physical, biological, and medical research to visit and meet Russian workers engaged in similar researches V O K S, the central institution in Moscow for organising cultural relations with foreign countries, is prepared to do everything possible to help the tour, and Intourist, the Soviet organisation for tourist parties, will consider giving specially reduced travelling charges Scientific workers desirous of joining such a tour are invited to write to the Secretary, Society for Cultural Relations with Russia, 1 Montague Street, London, W C 1

WHEN the late Sir Patrick Manson was addressing the Section of Tropical Diseases at the annual meeting of the British Medical Association in 1898, he said that there was not one of his hearers who did not bewail the crass ignorance in which he had lightly undertaken the care of men's lives in dangerous climates, nor one who could not pillory himself with the recollection of lives that perished owing entirely to the lack on his part of an elementary knowledge of tropical medicine Manson's address came under the notice of Joseph Chamberlain, who took action which resulted in the establishment of the London School of Tropical Medicine From that School, which Manson himself directed, and its successor, the London School of Hygiene and Tropical Medicine, some 4000 medical officers have gone to the far corners of the earth, trained in special post graduate courses in tropical medicine At the School on Feb 3, 1931, Dr Philip Manson Bahr will deliver a public lecture on "The Dawn of Tropical Medicine, being an account of the Life and Work of Sir Patrick Manson" The chair will be taken by Sir Harry Goschen, Bart, and admission is free, without ticket

THE Ministry of Agriculture and Fisheries has recently issued two advisory leaflets, one on "Swine Erysipelas" (No 17), another on "Blackhead of Turkeys" (No 20) Information is given on the symptoms, recognition, treatment, and modes of prevention of these diseases

The annual "Guide to the Spas and Marine Health Resorts of Great Britain and Ireland and New Zealand", by Dr R Fortescue Fox, has recently been issued (London J and A Churchill, 1s net) Information is given on the climates of coastal resorts and inland spas, with indications regarding the ailments for which they are best suited

THE "South African Journal of Science", vol 27, which is the report of the South African Association for the Advancement of Science, has just been published by the Association at Johannesburg, price 30s net The volume contains a statement of the constitution of the Association, the presidential addresses, and a complete collection of the papers read and published An account of the meeting, including brief notes on some of the papers, appeared in NATURE of Nov 29, p 862

A SECOND edition of the economic pamphlet No 112, entitled "The Cockroach its Life history and how to deal with it", by Mr F Laing, has recently been issued by the British Museum (Natural History) It provides a general account of the commoner species of these insects that frequent buildings, etc, and discusses means of their eradication This pamphlet will be found useful by anyone troubled with these pests, and is obtainable at the Museum in Cromwell Road, or through a bookseller, price 6*d* (postage 1*d*)

THE Departmental Committee on Maternal Mortality and Morbidity in an interim report which was published last July found that not less than one-half of maternal deaths in childbirth are preventable under suitable conditions The Ministry of Health has now issued a memorandum (*Memo* 156/M C W) with explanatory Circular (1167) to local authorities, directing their attention to this report, and urging them to exercise their full powers for the care of maternity Authorities are reminded that an additional amount of £5,000,000 for the development of the maternity and child welfare services was included in the general Exchequer contribution under the Local Government Act, 1929

DR EDWARD R WEIDLEIN, Director of the Mellon Institute of Industrial Research, announces that the Institute has lately begun a broad investigation into possible industrial uses for raw and refined sugar The research will be carried on by a multiple industrial fellowship sustained by the Sugar Institute, Inc, of New York, an organisation that represents the cane sugar refiners of the United States The investigation will be supervised by Dr George D Beal, assistant director of Mellon Institute, and by Dr Gerald J Cox, Senior Industrial Fellow Four chemists have begun the initial scientific research of the industrial fellowship, and additions will be made to this staff, as needed, from time to time

APPLICATIONS are invited for the following appointments, on or before the dates mentioned —An assistant lecturer in phonetics at the Glasgow Training Centre of the National Committee for the Training of Teachers—The Director of Studies, Training Centre, Jordanhill, Glasgow (Feb 2) A graduate in engineering for physics, mechanics, mathematics and machine drawing at the Southall Technical Institute—The Principal, Southall Technical College, Southall, Middlesex (Feb 2) A junior demonstrator in physiology at the University of Durham College of Medicine—The Registrar, College of Medicine, Newcastle upon-Tyne (Feb 2) A laboratory assistant in the Bacteriological and Pathological Laboratory, Birkenhead—The Town Clerk, Town Hall, Birkenhead (Feb 6) A principal of the High Wycombe Technical Institute—The Secretary for Education, Education Department, County Offices, Aylesbury (Feb 7) A head of the engineering department of the Leicester College of Technology—The Registrar, College of Technology, Leicester (Feb 21) An assistant in the London Museum—The Keeper, London Museum, St James's, S W 1 (Mar 14) An entomologist under the Indian Research Fund Association, able to undertake independent inquiries on malaria in the field or laboratory—The Secretary, Indian Research Fund Association, Simla, India (Mar 31) A woman lecturer in geography at the Warrington Training College, Liverpool—The Principal, Warrington Training College, Wavertree, Liverpool A full time teacher of draughtsmanship (engineering), under the London County Council—The Education Officer (S S 5), the County Hall, Westminster Bridge, S E 1

Our Astronomical Column

Light-Variation of Eros —*Beob Zirk*, No 3, contains some observations of maxima and minima of Eros, made at Hamburg-Grossborstel by M Beyer The principal period is still $5^h\ 16^m\ 14^s$, but the light range is notably smaller than it was at the beginning of December Similar changes of light range have been observed at other apparitions, they favour the theory that the planet is double, and that mutual occultations occur when the earth is near the plane of rotation, but not otherwise Duplicity ought to be detected by the great American telescopes at this near approach, if it exists Prof Yamamoto notes in *I A U Circ*, No 309, that even if the variation arises from regions of very different albedo on the planet's surface, it may cause the centre of light to be shifted some 0 1" from the centre of figure, which would be an appreciable amount in researches of such delicacy as are now being carried out There was a request to observers with large instruments to try to observe the shape of the planet, but no reports have yet been received on the subject

Locating the Sun's Corona —In *Comptes Rendus* for Nov 10, M Lyot, of the Meudon Observatory, describes work conducted by him during July and August last, at the observatory of the Pic du Midi, for detecting the sun's corona without the unique conditions afforded by a total solar eclipse M Lyot states that from his observing station the purity of the atmosphere was such that, by the interposition, in the optical train, of a metal disc slightly larger than the image of the sun formed by a 4 cm objective, the prominences at the sun's limbs were clearly visible without recourse to a spectroscope Working under these conditions with a very sensitive polariscope, he explored the sky immediately surrounding the sun's disc It was found that the proportion of polarised light (the plane of which appeared to be radial) was insensible at about 6′ from the sun's limbs but increased inwards M Lyot proved to his satisfaction that the origin of the polarisation was neither atmospheric nor instrumental, and he concludes that he has observed the polarisation of the sun's inner corona Figures for July 29 and 31 derived from the observations made at various position angles at a constant distance of 80" from the sun's limbs show two minima that correspond to the position of the sun's axis on those days A further substantiation was made by observing the strength and length of two bright lines of the spectrum that were visible with a direct vision spectroscope These lines were evidently the coronal lines λ5303 and λ6374, and their variation at different position angles around the disc corresponded generally with the degree of polarisation observed These results are of great interest, for they indicate a means of studying frequently certain attributes of the sun's corona that have hitherto been available to observation during the brief and infrequent occasions of a solar eclipse

Rotation of the Galaxy —Sir Arthur Eddington chose this topic as the subject for the Halley Lecture on May 30, which has been published at Oxford by the Clarendon Press After a brief historical sketch, he gives a proof of the formula published by Dr Oort a few years ago, which states that the radial velocities of the stars contain a term varying as twice the sine of their galactic longitude, this being measured from the centre of galactic rotation He notes that the same formula was published by Gylden in 1871 but did not then attract much attention

The formula gives two alternative positions for the galactic centre, diametrically opposite to each other The one in Sagittarius is now selected, on other grounds, but Gylden chose the one in Gemini Prof Turner had also been led to the position in Gemini by consideration of the two stellar drifts, but that method likewise gave two opposite positions as possible Dr Plaskett, in the George Darwin Lecture of the Royal Astronomical Society delivered last May, showed that the radial velocities of the stars of types *O* and *B* supported Oort's position of the centre, and further indicated that the interstellar gas shares the rotation of the stars Sir Arthur Eddington notes that, owing to the viscosity of this gas, it does not appear that its rotation could be maintained indefinitely, this tends to support the shorter time scale that limits the duration of the stellar system to a few thousands of millions of years, whereas the long scale gives millions of millions

Galactic rotation gives an explanation of the fact that the quick moving stars are all moving towards one hemisphere, those are really the laggards, and the sun is moving from them, not they from the sun Stars with high speed in the rotational direction would escape from the galaxy, the attraction of which could not control them They have already been eliminated Sir Arthur Eddington notes that the aspect of the spiral nebulæ is far from suggesting stability As our galaxy is believed to resemble them, this consideration also favours the shorter time scale The rapid recession of the spirals, if taken as real, is shown to provide an argument tending in the same direction

Research Items.

The Klamath—In 1925 and 1926 Mr Leslie Spier visited the Klamath of southern Oregon to study their religion and social organisation, now a thing of the past, but of which the memory still exists among some of the elder people who still occupy their old home The results of the investigation are published as vol 30 of the *University of California Publications in American Archæology and Ethnology* The Klamath are the northern of two major dialectic groups of the Lutuami linguistic stock, of which the southern is the Modoc The Klamath have the richer and more specialised culture They were first visited by whites in 1825 and 1826, at a time when the Snake Indian raids were at their height These raids probably account for the fact that country between the Klamath and the Dalles on Columbia river was unoccupied It is probable that in historic times their highest number was about 1200 Owing to lack of adequate information relating to the tribes of the region, it is difficult to place the Klamath in relation to surrounding cultures Their food habits and material culture generally follow the plateau peoples Although their river the Williamson river—was a minor stream, they are as much a river people as the Thompson, Lilloet, and Sushwap Their staple food was fish, supplemented by roots and seeds Deer and other game, though abundant, was not hunted Their mode of living was arbitrary and not decided by geographical conditions Klamath and Modoc represent the southern boundary of the plateau culture but they have a strong leaning toward north eastern California The basis of their religious experience is that of the northern interior the Columbia basin, and the north west coast Specifically the resemblance appears in the circumscription of spirit possession to the mid winter month Details of shamanism on the other hand link with north eastern California Social organisation is simple and like that of the basin and plateau in every particular

Tuberculosis in Man and Lower Animals—The material for an important memoir under this title by Dr H H Scott (*Medical Research Council, Spec Rep Series* No 149 H M Stationery Office, 4s net) is derived from post mortem examinations made by Dr Scott of 300 cases of fatal tuberculosis occurring among Chinese of the labouring class in Hong Kong, and from similar examinations of a series of wild animals dying of tuberculosis while in captivity in the Zoological Gardens, London He also reports upon some cases of mycosis in animals, the lesions of which are not unlike those of tuberculosis Interesting details are given of the kind of lesions and their distribution and histology in the various animals Thus in the dog, whitish circumscribed tumours with viscid or mucopurulent centres occur in the lungs, liver, and kidneys, which in their naked eye appearances simulate cancerous growths Microscopically, the tubercle of the dog differs from that found in man and most other mammals by the absence of giant cells In the parrot, which is susceptible to both the human and the avian types of the bacillus, pulmonary tuberculosis is rare and cutaneous infection is common, taking the form of lupoid or warty affections of the head Tuberculosis is of exceptional occurrence in cold blooded animals and the bacilli are of several types Lesions may be present in the lungs, liver, and intestine, and occasionally as a cutaneous infection Mycoses are commoner in birds than in mammals and double infection with tuberculosis is not infrequent. Dr Scott doubts the occurrence of tuberculosis in animals in the wild state

Musk-Ox in Sub-Arctic Canada—In continuing the account of his expedition to sub arctic Canada, to which we have already referred, Capt J C Critchell Bullock discusses the habits of the musk ox (*Canadian Field Naturalist*, Nov 1930, p 187) He does not agree with the notion that the musk ox is a migratory animal It is gregarious, and the band may indeed make periodical journeys, but these are usually due to lack of food in the northern haunts, where grass and willows do not grow so profusely as towards the southern limit of their range Apart from such movements, they prefer to associate themselves with a chosen locality, where they remain indefinitely Nor does the author agree with the report of the Royal Commission of 1922 upon the musk ox, as regards feeding habits Instead of showing preference for grass as compared with willows, moss, and lichens, as the report suggests, the musk oxen of the Thelon district were only once seen to eat grass where young shoots of willow bushes were available The species has been practically exterminated about the head waters of the Coppermine and Black's Rivers, and the evidence suggests that the policy of conservation is not resulting in the increased numbers hoped for In the musk ox country there were fewer signs of wolves than anywhere else, but it is possible that the grizzly bear may do some damage, though the likelihood is that the inland Eskimo has more to do with the reduction of a species which may still be said to be in no little danger of extermination A good omen, however was the observation of Capt Critchell Bullock that calves composed almost one third of the three bands he saw

Hydatid Disease This disease is a condition caused by the developmental stage of a tape worm which has its natural habitat in the intestine of the dog and occasionally in other carnivora The cystic or developmental stage is particularly met with in the sheep and in man, it is usually those who come in contact with sheep who develop the disease The disease is apparently rare in China and Dr H H Loucks, Department of Surgery Peiping Union Medical College, in a paper entitled 'Hydatid Cyst', reprinted from the *National Medical Journal of China*, vol 16, pp 402 496 1930 has been able to collect only twenty cases recorded in the literature, but during the last ten years he has been able to add twelve more undoubted cases, and five others in which a diagnosis rested upon clinical evidence only Full details of the cases, with a review of the literature on Chinese cases and a bibliography, are given

***Holacanthus bispinosus* in the Philippines** - Mr Heraclio R Montalban, of the Division of Fisheries Bureau of Science Manila, records this handsome fish for the first time from the Philippines ('A Chaetodont new to the Philippines", *Philippine Journal of Science*, vol 41, No 3, March 1930) and re describes it with a good coloured figure The description is taken from two specimens, 78 5 mm and 81 mm in length, from Lumbian Islands, Sulu Archipelago Previous records are from Zanzibar Amboina, New Hebrides, Tahiti, Samoa, and the Hawaiian Islands The fish bears some resemblance to *Holacanthus multispinis* Playfair, but is distinguished at once from the latter by the absence of a shoulder blotch

Fauna of Lancashire and Cheshire—An interleaved check list of the fauna of Lancashire and Cheshire ("A Check List of the Fauna of Lancashire and Cheshire', pt 1 Arbroath T Buncle and Co

5s. net) has been edited with great care by the secretary of the Fauna Committee of these two counties, Mr A K Lawson, and has a preface from the pen of Prof W M Tattersall, of University College, Cardiff Twenty two orders, ranging from Mammalia to Oligochæta, are included, and the number of insects, spiders, birds, fishes, mites, mammals, worms, and other creatures amounts to upwards of four thousand Mr Coward is responsible for the Mammalia (50 species), Aves (288), Reptilia and Amphibia (both 6 species), and non marine Pisces (32) Of ants Mr Donisthorpe records 27 forms, there are 1920 Coleoptera, 414 Hemiptera in two almost equal divisions, and 157 Tenthredinidæ classified by Mr Britten Mr Lucas deals with the Mecoptera (3) Neuroptera (28) Paraneuroptera (23), and Orthoptera (34) There are 22 species of Siphonaptera and no fewer than 467 Arachnida The latter, together with the Opiliones (15 species) and Pseudoscopiones (14), are treated by Mr Falconer, who, together with the Rev J E Hull, is responsible for the Acari (345 species) Prof Tattersall and Mr Britten record a hundred and one Crustacea, Dr Wilfrid Jackson 143 Mollusca, and the Rev Hilderic Friend 42 Oligochæta, or land and fresh water worms, with nine different parasites found in the same Few counties can show so large a record, which is a testimony to the industry of the members of the county natural history societies and the recorders

Use of Compost for Turf – The use of compost in horticulture is nothing novel but it has been little employed for the improvement of turf A series of articles in the *Journal of the Board of Greenkeeping Research* vol 1, No 3 shows how it may be applied to golf greenkeeping The preparation and usage of compost is dealt with by R B Dawson The term is applied to a mixture of soil and organic material piled up in alternate layers and allowed to rot Heavy clay or pure sand should be avoided and horse stable manure is the most favoured type of organic matter, but peat moss leaves grass cuttings spent hops and seaweed are also mentioned as satisfactory The stack must be protected from rain, both to facilitate subsequent sieving and also to prevent putrefaction and loss of valuable fertilising materials A compost heap is best started in the spring and should be allowed to stand undisturbed for one or preferably two years before use, February and March being the best season for treating the turf The American system is to apply one ton (1 cub yd) of screened compost per month per 5000 sq ft usually accompanied with 10 25 lb sulphate of ammonia However, considerable benefit is obtained with smaller quantities and an application of one ton in the spring followed by monthly dressings of 5 10 cwt , to which sulphate of ammonia and sulphate of iron have been added for weed destruction, is suggested The chief objections against the use of compost are based on the possible introduction of weeds This difficulty can be entirely overcome by sterilising the compost before use, and practical details of the plant in use at the Malone Golf Club Belfast, are described by J Henderson Baking appears to be the best method of procedure and the cost of 1s 6d per ton is not considered prohibitive The advantages from the use of compost are various It tends to level the turf and encourages bottom growth of grass, it acts as a valuable carrier for the distribution of fertilisers, itself supplying humus and small amounts of plant food, and also exerts a protective action under conditions of drought or frost

Huygens and other Lens Makers of the Seventeenth Century – The addresses delivered by Dr P Zeeman, Prof Picard, and others in the hall of the Academy of Sciences at Leyden in celebration of the tercentenary of the birth of Christian Huygens on April 14, 1629, have been issued in pamphlet form by Paris of Amsterdam, along with Dr C A Crommelin's guide to the exhibit of Hugeniana in the Observatory, illustrations of apparatus three portraits of Huygens, and a view of his home during a considerable part of his life in Holland In a further pamphlet by the same publisher, Dr Crommelin gives an account of the lens makers of the seventeenth century, with portraits and figures of their grinding apparatus Although Descartes invented a grinding machine, he does not appear to have made lenses Huygens and his brother Constantin began to grind lenses in 1655, and illustrations of their machines are given as well as those of Hooke Hevelius Maignan, and several taken from Zahn s ' Oculus artificialis' of 1685 Gutschoven Calthof, Mocchi, Reeves Campani Divini, Hartsoeker Spinoza, Leeuwenhoeck and Le Bas are all mentioned as lens makers, but no details of their methods are given Dr Crommelin s pamphlet forms a valuable addition to the papers of von Rohr and Baxendall which have appeared recently in the *Transactions* of the Optical Society

Interaction of α-Particles and Helium Nuclei – It has recently been shown by Dr J Chadwick that the collisions between α particles of medium speed and helium nuclei do not follow the law of the original theory of scattering but that they behave instead in a modified way because of interference between the material waves of the two similar particles Dr Chadwick s results were taken to as small velocities of the particles as were conveniently studied by the scintillation method P M S Blackett and F C Champion, in an investigation with a Wilson cloud apparatus described in the January number of the *Proceedings of the Royal Society* have now carried these further and again obtained good agreement between their measurements of forks on α particle trails at the end of the range in helium and the predictions of the wave mechanics The statistical element in this work is more important than in Dr Chadwick s in spite of the fact that trails of about 50 000 α particles from polonium were examined, but the agreement remains on the whole very satisfactory A new result of importance which has been obtained incidentally in connexion with the present work is the relation between the speed of very slow α particles and the residual range in air under standard conditions

Isotopes of Zinc, Tin, Chromium, and Molybdenum A description of the isotopes of these four elements which have been successfully studied by the introduction of volatile methyl compounds and carbonyls into the apparatus, is given by Dr F W Aston in the January number of the *Proceedings of the Royal Society* In the case of zinc and tin the order of intensity of the isotopes has been revised and with the other metals new isotopes have been discovered In all cases, very good agreement is found between the chemical atomic weight, as deduced from the masses and relative abundance of the various isotopes, and that obtained by the more usual direct chemical methods The actual numbers for these constants from mass spectrograph data are $Zn-65\ 38_0 \pm 0\ 02$, $Sn\ 118\ 72 \pm 0\ 03$, $Cr\ 52\ 001 \pm 0\ 006$, and $Mo-95\ 97 \pm 0\ 06$ Dr Aston has not been able to obtain new results for cadmium and germanium Cadmium methyl, although chemically similar to zinc methyl, behaved in a totally different way in the discharge, cadmium depositing on the walls and disturbing seriously the normal beam of

rays Germanium was studied by germanium ethyl, by use of which it had already been shown that there are eight isotopes to this element, but no satisfactory quantitative results were obtained Dr Aston proposes to study germanium later with the methyl compound, but it appears that with cadmium it will be necessary to return to the more difficult technique of 'anode rays', by which its isotopes were first discovered

Beam 'Arrays' in Short-Wave Transmissions—During the last three years the technique of short wave transmission of electric waves through space has been rapidly developing It is interesting to remember that so far back as 1899, S G Brown took out a patent for an aerial which utilised the principles of interference now commonly adopted The first successful high speed radio telegraph service was inaugurated at Bodmin, Cornwall, in 1927 by Franklin and Marconi They developed a method of short wave generation, which enabled engineers to design transmitters able to supply a large output at a steady frequency The transmitters used in short wave transmission are 'arrays' of wires scientifically spaced and carrying currents in the correct phases so as to increase greatly the resultant field strength in a definite direction In a paper read to the Institution of Electrical Engineers on Dec 3, T Walmsley described many of the beam 'arrays' which are used in different countries, and in particular his own 'T W' aerial array which is used at the Post Office radio station at Rugby He pointed out that the question of suitable transmission lines to the 'array' is of great importance The Marconi beam stations, the French and the German stations, all use concentric tube transmission lines Mr Walmsley, however, pointed out that the losses in open circuit lines are much less than most engineers think, and so they can in many cases be usefully employed Provided that the currents in the lines are well balanced, the radiation losses are small There are losses in open circuit lines due to the 'high frequency' resistance, the proximity of the wires, the dielectric losses in the insulators, and the reflections from points on the circuit where the electrical constants change He suggested methods for reducing these losses

Problems in Lighting Systems—Dr W T Walsh, of the National Physical Laboratory, has contributed an interesting paper on photometric research to *World Power* for January In considering the merits of any lighting system it is necessary to take 'glare' into account It is found that the sensitivity of the eye is diminished four fold if a light source of sixty candles is placed 10 feet from the observer, when the line joining the source to the eye makes an angle of 3° with the line of sight The rate at which the eye loses sensitivity when a light suddenly appears and the rate at which it recovers when the glare is removed are being investigated There is at Teddington a model street, 500 feet long and 35 feet broad, which is well adapted for tests of street lighting fittings In particular, the reflection from the road surface when the light is incident very obliquely and the angle of view is nearly horizontal has to be studied Every material used as a road surface, no matter how rough it may seem, shows a large amount of specular reflection under these conditions When the road is slightly worn the degree of polish is very marked Another problem that has been successfully solved is the most economical size of 'light well' to use for large blocks of buildings It is now possible from the curves and formulæ that have been published, to compute with sufficient accuracy the amount of light which will reach any point of a room facing a light well of given dimensions A problem of practical importance is to design a picture gallery so as to avoid the annoying reflections on the glass with which the pictures are covered The only satisfactory solution appears to be to arrange the windows so that as little light as possible falls on the spectators, while the full amount reaches the picture wall

Chlorine Monoxide—Goodeve, in the December issue of the *Journal of the Chemical Society*, describes experiments on the vapour pressure of chlorine monoxide, Cl_2O, which indicate that the boiling-point at 760 mm pressure is 2 0° and not 3 8° as found by Goldschmidt The freezing point is abnormally low, being −116° The value −20° reported in tables (without indication of the origin) is, therefore, much too high The vapour pressure curve of chlorine monoxide lies above that of chlorine dioxide found by Partington and King, and considerably below that of chlorine The value of the Trouton coefficient indicates that the liquid is probably not associated

Heats of Dilution—Some accurate experiments on the heats of dilution of potassium chloride in sugar and urea solutions at 25°, with concentrations below 0 1 molar, are described by Lange and Robinson in the November number of the *Journal of the American Chemical Society* The object of adding the non electrolytes was to vary the dielectric constant of water and its rate of change with temperature, the values for pure water being used in the case of solutions in which these substances were absent A linear relation at low concentrations with $\sqrt{c}$ was found, but the curves for sugar and urea were different Although agreement with theory was not obtained, it was concluded that the existing data on dielectric constants made exact comparison impossible

Nitrogen Tri-iodide—The composition of nitrogen iodide appears to vary according to the method of preparation, the ordinary substance being regarded as NI_3 NH_3 or NH_2I In the December issue of the *Journal of the Chemical Society*, Cremer and Duncan describe some experiments on the action of dry ammonia on iodine bromide or, more conveniently, a polyhalide such as $KIBr_2$, which dissociates into potassium bromide and iodine bromide In these reactions NI_3 is formed The more stable dibromo iodides, such as those of tetramethylammonium and trimethylsulphonium, do not react in this way, but form additive compounds with ammonia The iodide of nitrogen was obtained by washing with water the product of the action of ammonia gas on the polyhalide, and was a black explosive powder

Complex Salts of Bivalent Silver—Although silver is normally univalent, its analogies with copper suggest that it should also function as a bivalent metal The earliest observations on bivalent silver salts were made by Barbieri in 1912 He obtained a compound of argentic persulphate with pyridine, [Ag 4 py] S_2O_8, and in 1927 obtained the corresponding nitrate In the December number of the *Journal of the Chemical Society*, G T Morgan and F H Burstall describe some further co-ordination compounds of bivalent silver in which both two and three diamine complexes (occupying two co ordination positions) are present, indicating that the co ordination numbers 4 (as in Barbieri's compounds) and 6 are possible for bivalent silver The addendum employed was aa^1 dipyridyl, and the following compounds were obtained $[Ag_2\ 5\ \text{dipy}]S_2O_8$, $[Ag_2\ 5\ \text{dipy}](S_2O_8)_2$; $[Ag\ 3\ \text{dipy}](NO_3)_2$, $[Ag\ 3\ \text{dipy}](ClO_3)_2$, $[Ag\ 3\ \text{dipy}](ClO_4)_2$, $[Ag\ 2\ \text{dipy}](HSO_4)_2$

Prize Awards of the Paris Academy of Sciences

AT the annual public meeting of the Paris Academy of Sciences the prizes and grants for 1930 were awarded as follows

Mathematics.—The Poncelet prize to Arnaud Denjoy, for the whole of his mathematical work; the Francœur prize to Eugène Fabry, for his work on the singularities of analytical functions.

Mechanics.—The Montyon prize to Paul Le Rolland, for his work on the measurement of hardness by means of the pendulum; the Henri de Parville prize to Émile Duchêne, for his work in ballistics.

Astronomy.—The Lalande prize to Nicolas Stoyko, for his theoretical and practical work on the calculation of planetary orbits; the Valz prize to Gilbert Rougier, for his work on photoelectric cells; the Janssen medal to Bernard Lyot, for his experimental work on the polarisation of light from the planets; the Pierre Guzman prize to Alexandre Véronnet, for his works on cosmogony; the La Caille prize to Mme Edmée Chandon, for her work on the tides of the Red Sea.

Geography.—The Delalande Guérineau prize to Félix Ollivier, for his book "La topographie sans topographes"; the Gay prize to André Guillaumin, for his work on the flora of the islands of the Pacific; the Tchihatchef foundation to Jean Bathellier, for his contribution to the systematic and biological study of the Termites of Indo China; the Binoux prize to Georges Poivilliers, for his work on the application of photography to topography.

Navigation.—The Prix de la Marine to Robert Bureau and Philippe Wehrlé for their meteorological work in connexion with aerial navigation; the Plumey prize to Paul Régnauld, for his work on the strength of materials used in the construction of steamships and boilers.

Physics.—The La Caze prize to Henri Abraham, for the whole of his scientific work; the Hébert prize to Richard Langlois, for his memoir on asynchronous machines with rotating fields; the Hughes prize to Alexandre Dauvillier, for his work on the X rays; the Clément Félix foundation to Jean Lecomte, for his work on the infra red.

Chemistry.—The Montyon prize (unhealthy trades) to Roger Douris, for his work on poisonous gases; the Jecker prize to Joseph Bougault, for the whole of his work in organic chemistry; the La Caze prize to Georges Denigès, for the whole of his work in analytical chemistry; the Cahours foundation to Lucien Andrieux, for his researches on the electrolysis of metallic oxides in solution in fused boric acid, borates, or fluorides; the Houzeau prize to Paul Mondain Monval, for his work in physical chemistry.

Mineralogy and Geology.—The Cuvier prize to Maurice Gignoux, for the whole of his geological work; the Joseph Labbé prize to Jean Jung, for his geological work applied to prospecting for petroleum deposits.

Physics of the Earth.—The Victor Raulin prize to Albert Baldit, for his work on the influence of the relief and nature of the soil on the meteorological elements.

Botany.—The Desmazières prize to Frédéric Bataille, for his researches in mycology; the Montagne prize to Pierre Allorge, for his work on the Muscineæ and fresh water Algæ; the de Poincy prize to Mlle Aimée Camus, for the whole of her botanical work.

Anatomy and Zoology.—The Da Gama Machado prize to Marcel Avel, for his experimental researches on the somatic sexual characters of *Lumbricus*; the Savigny foundation to Louis Parrot, for his studies in the biting Arthropods, particularly in North Africa; Jean Thore prize to Henri Bertrand, for his researches on the larval evolution and metamorphoses of the Coleoptera.

Medicine and Surgery.—Montyon prizes (2500 francs) to Marcel Aynaud, Henri Lagrange, and Lucien Viborel; honourable mentions (1500 francs) to Paul Blum and Ernest Schaaf, to Noël Fiessinger, Henri René Olivier and Maurice Herbain, and to Henri Fischer; citations to Charles Mayer and to Gustave Rappin; the Barbier prize to Léopold Lévi, for his researches on the endocrine glands; the Breant prize between Julien Dumas (2500 francs), for his work on the bacillus of dysentery, and Stefan Nicolau, Ian Alfred Galloway, and Mme Octavie Dimancesco Nicolau; the Godard prize between Jules Janet, for his memoir on the diagnosis and treatment of blennorrhagia in man and in woman, and Pierre Gley, for his work relating to the yellow body and ovulation; the Mege prize to Henri Vignes, for his book on gynæcological physiology and medicine of women; the Dusgate prize to Henry de Varigny, for his work on death, true and false; the Bellion prize to Jean Bordas, for his work on the hygienic and economical treatment of manure; the Baron Larrey prize to Joseph Maisonnet, Daniel Petit Dutaillis, and Théophile Alajouanine, for their memoir on the remote after effects of trepanning; the Alfred Dutens prize between Henri Bordier, for his memoir on diathermy and diatherapy, and Georges Bourguignon, for his work relating to chronaxy.

Physiology.—The Montyon prize to Charles Porcher, for his book on milk from the colloidal point of view; the L. La Caze prize to Maurice Doyon, for the whole of his work in physiology; the Pourat prize to Henri Delaunay, for his researches on the nitrogenous excretion of the Invertebrates; the Martin Damourette prize to Jean Régnier, for his researches on the influence of hydrogen ions on physiological phenomena and on anæsthetics; the Philipeaux prize to Jacques Millot, for his work on the physiology of the Araneidæ.

Statistics.—The Montyon prize to René Roy, for the whole of his work on the application of mathematics to statistics and economics.

History and Philosophy of Science.—The Binoux prize (in equal parts) between Pierre Brunet and Niels Nielsen.

Works of Science.—The Henri de Parville prize to Raoul Combes, for his work on the life of the plant cell; the Jeanbernat Doria prize to Henri Volkringer, for his book, "The Stages of Physics".

Medals.—Berthelot medals were awarded to Roger Douris, Joseph Bougault, Georges Denigès, and Paul Mondain Monval.

General Prizes.—The prize founded by the State to Georges Valiron, for his work on analytical functions; the Bordin prize to Louis Dangeard, for his contributions to our knowledge of the sea floor; the Lallemand prize to Michel Raoul May, for his work on the nervous system and the grafting of sense organs; the Vaillant prize to Robert Perret, for his topographical and geological map of the mountains between the valleys of Chamonix and Sixt; the Le Conte prize to Elie Cartan, for the whole of his mathematical work; the Houllevigue prize to Georges Giraud, for the whole of his work on partial differential equations; the Saintour prize to Elie Ivanow, for his researches on the artificial impregnation of mammals; the Jules Mahyer prize to Constantin Dawydoff, for the whole of his researches in zoology and especially on the embryo

geny of the Vertebrates, the Henry Wilde prize between Maurice Leriche (2000 francs), for his palæontological researches, and Ferruccio Zambonini, for his work in mineralogy, the Caméré prize to David Wolkowitsch, for his memoir on the applications of geometry to the stability of constructions, the Gustave Roux prize to Marc André, the Thorlet prize to Adolphe Richard, the Albert I of Monaco prize to Lucien Cuénot, for his biological work

Special Foundations —The Lannelongue foundation to Mmes Cusco and Ruck, the Hélene Helbronner Fould prize to the late Mme Yves Delage

Prizes of the Grandes Écoles -The Laplace prize to Henri Feltz, the L E Rivot prize between Henri Feltz Pierre Julien Couture Émile Bideau, and Camille Henri Foin

Foundations for Scientific Research —The Gegner foundation to Désiré Bois for his book on the history, utilisation, and culture of plants used for food, the Jérome Ponti foundation to Robert Forrer for his work on magnetism the Hirn foundation to Maurice Kraitchik, for his studies in the theory of numbers, the Henri Becquerel foundation to Jean Thibaud for his work on X rays of long wave length and the joining up the ultra violet and X ray spectra, the Victor Noury foundation between Augustin Boutaric (3000 francs), for his work on colloids, Henri Baulig (3000 francs) for his book on the central plateau of France and its Mediterranean border, morphological study, the late Franz de Zeltner (2000 francs), for his work in western Africa Pierre Lamare (2000 francs), for his geological researches in the Yemen, and Raymond Hovasse for his biological and zoological work, the Charles Bouchard foundation to Léon Binet for his experimental researches on apparatus for perfusion and artificial respiration the Henry Le Chatelier foundation to Marcel Ballay for his researches on the beryllium alloys, the Pierre Lafitte foundation to Raymond Jouaust, for the whole of his work on radio electricity, the Roy Vaucouloux foundation to Joseph Magrou, for his work on the production of tubercles and galls in plants

THE LOUTREUIL FOUNDATION

The Academy has considered twenty nine applications for grants from this fund, and has made the following twenty two awards amounting in all to 121,000 francs

1 *Researches on Definite Problems* —10,000 francs to Louis Dunoyer, for the extension of his researches on photoelectric cells, 5000 francs to Raymond Ricard, for his researches on the spark spectra of metals, 5000 francs to Jacques Duclaux, for his work on the measurement of the transparency of the atmosphere, 4000 francs to Maurice Fontaine, for his researches on the physiology of marine organisms 3000 francs to François Maignon, for the continuation of the study of the influence of the seasons and of the genital glands on respiratory combustion, 3000 francs to Gabriel Petit, for his researches on the grafting of endocrine glands, 3000 francs to Jean Verge, for his researches on d'Herelle's bacteriophage and its applications in veterinary medicine 4000 francs to the viticulture laboratory of the National Hygronomic Institute (Director, Pierre Viola), for various researches in plant pathology now in progress

2 *Voyages and Exploration* —5000 francs to Charles Alluard, as a contribution towards an expedition to the southern Sahara 3000 francs to Norbert Casteret, for his spelæological explorations in the Pyrenees, 4000 francs to Auguste Méquignon, for the continuation of his entomological researches in the Azores archipelago

3 *Purchase of Material* —3000 francs to Emilio Damour for the completion of the installation of the glass laboratory at the Conservatoire national des arts et métiers, 3000 to Jean Georges Lafon, to complete the installation of electro cardiography at the physiological laboratory of the National Veterinary School of Toulouse, 1000 francs to the Arcachon Scientific Society, as an aid to building

4 *Libraries* —15,000 francs to the National Museum of Natural History, for producing a catalogue of the books contained in the laboratory libraries, 12,000 francs to the Lyons National Veterinary School, and 4000 francs to the Toulouse National Veterinary School, for increasing their libraries

5 *Publications* —5000 francs for the Fauna of the French Colonies, 5000 francs to the French Federation of Societies for Natural Science 15,000 francs for the continuation of the catalogue of the scientific periodicals in the libraries of Paris, 5000 francs to Emmanuel de Margerie, for the preparation of a geological map of Africa, 4000 francs to the Science Museum of Lyons, for assisting the publication of a memoir by L Germain on the Helicides of the French fauna

Fruit Cultivation in Great Britain

AMONG the recent bulletins issued by the Ministry of Agriculture those entitled "Fruit Production—Tree Fruits, No 2", and "Fruit Production—Soft Fruits and Nuts, No 4", are particularly welcome, as in the present economic condition of the commercial fruit growing industry all available information as to the results of recent research should be studied by growers, and, where possible, applied to the elucidation of the many problems connected with this highly specialised calling In these publications the amateur and the professional grower have access to much valuable advice, written in language at once clear and concise and not overburdened by technical terms

The factors dealt with in the opening chapter on the planning and planting of an orchard merit close attention, as miscalculations on these matters are of frequent occurrence and in after years are extremely difficult to rectify

The question of shelter is dealt with briefly, but it is difficult to over emphasise its importance in the economy of a commercial plantation, as losses from high winds occur annually, and are occasionally of a very serious character Three conifers are recommended as wind breaks, but they are comparatively expensive An excellent shelter belt may be formed by planting a mixture of common larch and spruce fir, which in a young state may be purchased at a cheap rate

Information as to progress made in classification and suitability of vegetatively propagated stocks for various purposes is extremely helpful, as many amateurs fail to realise the influence of 'pedigree' stocks on the future behaviour of their trees It is suggested that vegetatively propagated stocks, such as East Malling Types X, XII, XIII, XV, and XVI, may replace seedling stocks, but the existence of numerous orchards containing very large but possibly unremunerative apple trees testifies to the vigour of the stocks employed by earlier planters, and further information is desirable as to the ability of these standardised stocks to withstand the deleterious effects of grass

The bulletin rightly stresses the importance of a rigid selection of plum stocks, and condemns the

practice of utilising suckers, carelessly taken from plum orchards for propagation purposes, owing to the risk of working stocks infected with 'silver leaf'.

The thorny subject of pruning is dealt with in a masterly manner, and the section devoted to this important operation will appeal to the many amateur fruit growers who, owing to well meant but occasionally contradictory suggestions of numerous advisers, are hopelessly at sea on this matter. The general principles are clearly indicated; it is pointed out that no hard and fast rule can be applied to all species and varieties, but that the system of pruning should be modified in accordance with their special characteristics.

It is doubtful if the extended commercial cultivation of pears in Great Britain is worthy of consideration, as imported produce of high quality is now available for the greater part of the year. Much useful information respecting up to date storage methods is contained in a chapter devoted to this subject, but further research is needed.

Renovation of old orchards and the control of pests and diseases of fruit trees are ably dealt with, and the bulletin should be in the hands of all who wish to see an improvement in the general standard of fruit culture, and are interested in the future of an important home industry.

Bulletin No. 4 deals with 'soft fruits', which now form an important section of the British fruit industry, and its contents comprise the more important results attained by research workers and also details of sound cultural methods.

The descriptive lists of *standard commercial* varieties should be of great assistance to intending planters, and information respecting varieties suitable for canning will enable growers to cater specially for this purpose. Black currants and gooseberries in recent years have failed to give remunerative returns, and the area devoted to those crops will probably decrease. Figs and melons are among the fruits included in the bulletin, but their commercial cultivation is likely to remain in the hands of a comparatively few growers. Cob nuts and filberts realise high prices and there appears to be ample scope for their extended cultivation; the nut is not fastidious as to soil, but possibly the prevailing system of land tenure is responsible for the small area devoted to this and other 'permanent' crops.

Rainfall of the United States

SUPPLEMENT Number 34 of the *Monthly Weather Review* of the United States Department of Agriculture is a summary giving the main results of fifty years of organised rainfall measurement, in the form of daily, fortnightly, monthly, and annual normals of precipitation for the regular first order stations of the U.S. Weather Bureau.

The need for a revision of the normals for the United States available before this publication appeared arises from the fact that the last revision was made so long ago as 1907, since when many new stations have been started. The new normals all refer to the period January 1878 to December 1927 inclusive. Where a complete record has not been available, the usual procedure has been adopted, namely, an adjacent station has been selected for which the full fifty years' record is available, and its measurements have been compared with those at the station with the incomplete record throughout the period of overlap of the two records. In this way the relative degree of wetness has been obtained, and thence a correction which, when applied to the normal computed from the period of overlap, gives a close approximation to the required normal.

A publication of this kind, consisting of little more than a vast array of figures in tabular form, is clearly not to be regarded as reading matter in the ordinary sense even for the expert meteorologist. It would, however, have been more nearly so had there been a key map showing the positions of all the places for which normals are given, preferably with shaded or coloured altitude zones, and any other features that might assist in explaining the great diversity in the amount and seasonal distribution of the precipitation, which a careful inspection of the tables reveals. For the work has under review the rainfall of a country in which virtually rainless areas exist side by side with areas of great altitude and wetness, where lofty mountain peaks force the moist westerlies from the Pacific to rise and undergo such dynamical cooling that a large proportion of their moisture is condensed to rain or snow. A rapid survey of the normal annual falls did not reveal any total that is not surpassed in the Lake District of England, but showed many smaller than can be found anywhere in the dry eastern lowlands of England and Scotland. Yuma, Arizona, has the interesting annual normal of 3.47 inches, based on a full fifty years' record.

In addition to its value in general climatology, this work is obviously of the first importance to American water engineers and to many of the industries of the States, particularly farming. E. V. N.

Parliamentary Representation of the Universities of Great Britain

IN view of the clause relating to the abolition of university constituencies which appears in the Representation of the People Bill, the text of which has recently been issued, a joint memorandum has been submitted to the electors of the Universities of Oxford and Cambridge by their present parliamentary representatives. The memorandum gives a brief history of university representation in Great Britain. In 1603 James I., by a charter issued on the advice of his Attorney General, Sir Edward Coke, granted to the Universities of Oxford and Cambridge the right, which they have ever since enjoyed, of each returning two burgesses to Parliament. A similar right of representation in the Irish Parliament was accorded to Trinity College, Dublin, ten years later. By the time of the outbreak of the War there were nine university members in the House of Commons, returned by the following constituencies:

	Voters
Oxford (2)	6,895
Cambridge (2)	7,145
Dublin (2)	5,020
London (1)	6,070
Edinburgh and St. Andrews (1)	11,319
Glasgow and Aberdeen (1)	11,714
	48,163

A large measure of parliamentary reform and a great extension of the franchise were undertaken by the Coalition Government in 1918. Three new university constituencies, the Combined English Universities,

the University of Wales, and Queen's University, Belfast, were created, and the Scottish universities were awarded an additional member At the same time, reforms were effected in the qualification for the university vote which immensely increased the number of voters in the existing university constituencies, particularly in Oxford and Cambridge It was also enacted that whenever a university constituency returned two or more members, the elections should be conducted according to that variety of proportional representation known as the single transferable vote

As a result of these reforms, the university constituencies, at the date of the general election in 1929, were as follows

	Voters
Oxford (2)	15,770
Cambridge (2)	23,978
London (1)	15,558
Scottish Universities (3)	43,192
Combined English Universities (2)	13,775
University of Wales (1)	3,623
Queen's University, Belfast (1)	3,324
	119,220

In place, therefore, of five constituencies (if Trinity College, Dublin, be omitted) with 43,143 voters returning seven members, there are seven constituencies with 119,220 voters returning twelve members Nor is the process of expansion nearly completed, especially at Oxford and Cambridge Although these two constituencies have more than doubled in numbers since the franchise was altered in 1918, they will undoubtedly double themselves again in the next twenty years, as the existing regulations, which provide for the automatic registration of all British subjects who take degrees, gradually equate the number of voters with the number of living graduates of the university It may therefore, be predicted that if the representation of the universities in Parliament is left undisturbed for a generation, the twelve members will be representing a body of between 200,000 and 250,000 graduates

When account is taken of the very large numbers of men and women students, from all grades of society, including those who began their education in our primary schools, who now make their way to Oxford and Cambridge, and of the still larger numbers who proceed to the Scottish and the modern English universities, of the pronounced success which has attended the efforts of the universities to provide a training suitable to students entering on professional, commercial, or industrial careers, and of the fact that the general widening of the educational ladder has not yet had time to bear its full fruit, it is claimed that graduates of the universities of Great Britain, as a whole, represent to-day, even more fully than they did half a century ago, that section of the community which exercises the greatest influence on the formation of public opinion

Of 1263 men students matriculated at Oxford during the academical year 1928–29, less than half came from the English public schools Of the remainder, 179 were students from overseas, and 445 were from secondary schools which do not rank as public schools Of these 445, no fewer than 223 had started their education in public elementary schools, which means that at any time there are about 750 elementary schoolboys in residence at Oxford, and the proportion to the whole would be at least as large amongst the women students The evidence also shows that more than 45 per cent of Oxford undergraduates are in receipt of financial assistance without which their parents would be unable to give them a university education The figures for Cambridge are similar, and at some of the modern English universities more than two-thirds of the students began their education in the elementary schools

Further justification for the existence of a small number of university representatives in the House of Commons is found in the special knowledge they may be expected to have of the needs of higher education and educational policy generally The independence from government control enjoyed by the universities of the British Empire can only be maintained by very cordial co operation between the governing bodies of the universities and the Government of the day, and in the delicate negotiations which such co operation constantly involves, the university members play a part which is essential, although it naturally does not bulk in the public eye

The university constituencies, by reason of their peculiar constitution, provide for the enfranchisement of a large number of men and women who would otherwise be without a vote Since the university voter is placed on the register for life, and can vote through the post, he carries his qualification with him wherever he goes, he can exercise it although, owing to a change of residence, he may be without an ordinary vote, or unable to travel to a constituency to exercise it if he goes abroad, he can appoint a proxy, and, with the recent extension of air mails, he can now exercise the franchise himself from a great many distant parts of the world A careful analysis of 900 consecutive voters on the Oxford Register showed that no fewer than 75 had addresses overseas, many of them serving their country in distant parts of the Empire, which means that at Oxford alone the abolition of the University seat would disfranchise nearly 1500 overseas voters In the Scottish universities the proportion of overseas voters is probably higher

University and Educational Intelligence

CAMBRIDGE —Applications are invited for a research studentship at Emmanuel College, the maximum annual value of which will be £150 and the period of holding two years or a possible third Preference will be given to candidates who have completed one but not more than two years of research work Applications must be received by the Master of Emmanuel College by, at latest, June 30

THE Air Ministry announces that five hundred aircraft apprentices, between the ages of fifteen and seventeen years, are required by the Royal Air Force for entry into the Schools of Technical Training at Halton Bucks, and at Cranwell, near Sleaford, Lincs They will be enlisted as the result of an Open Competition and of a Limited Competition, to be held in the near future by the Civil Service Commissioners and the Air Ministry respectively Boys in possession of an approved first school certificate may be admitted without other educational examinations The scheme offers a good opportunity to well educated boys of obtaining a three years' apprentice course of a high standard The principal trades open to them are metal rigger, a new trade brought into existence by the introduction of the metal aeroplane, which involves training in both fitting and sheet metal work, fitter (aero engine), fitter (armourer), wireless operator-mechanic, and electrician Full information regarding the examinations can be obtained upon application to the Secretary, Air Ministry (Aircraft Apprentices' Dept), Gwydyr House, Whitehall, London, S W 1

Birthdays and Research Centres.

Feb 3, 1872 —Prof F J COLE, F R S , professor of zoology, University of Reading

My chief studies at present are concerned with the history of zoological discovery

Feb 4, 1875 —Dr LUDWIG PRANDTL, For Mem R S , director of the Kaiser Wilhelm Institute for Research on Fluid Flow at Göttingen

In the Wilbur Wright Lecture before the Royal Aeronautical Society in May 1927, I pointed out that after the very satisfactory explanation of the lift on aerofoils and of all similar related problems, it is necessary to investigate the problem of resistance more closely, and that turbulence is an important factor in connexion with this latter question Turbulence is that internal unrest in fluid motion which produces a continual mingling of fluid particles from the neighbourhood of the wall with those somewhat farther away, and as a result, frictional forces are increased, but the stream line pattern approximates more closely to the form calculated for ideal fluids

During the last few years, the investigations in my Göttingen Laboratory have gone into the properties of turbulent flow in great detail, and have, in fact, produced several important explanations But much remains to be done, and much more work is necessary before the experimental results can be explained with the desired clarity

Feb 5, 1866 —Sir ARTHUR KEITH, F R S , Hunterian professor and Conservator of the Museum of the Royal College of Surgeons

I am continuing my lifelong search for evidence bearing on the origin of man and of anthropoid apes Especially am I concerned with factors which regulate or influence development and growth

Feb 6 1852 —Dr CONWY LLOYD MORGAN, F R S , emeritus professor of psychology in the University of Bristol

One who enters on his eightieth year is not likely to be able to furnish an interim report of any new investigation now in progress More probably he asks himself What should I do were I near the start of my life work instead of fast approaching its close ?

Realising that comparative psychology is still in its infancy, I should concentrate attention for another lifetime on the earlier stages in the evolutionary genesis of mind in its natural process of concrescence I should still urge that, since maturity is, in each individual, a novelty emergent on infancy, it does not accord with sound method in science to account for infantile (and even embryonic) occurrences in terms of mature processes if, on the available evidence, such processes are not as yet emergent in that instance of concrescent advance which is under scientific consideration

Feb 6, 1871 —Lieut Col J STEPHENSON, F R S , Indian Medical Service (retd), formerly lecturer in zoology in the University of Edinburgh

The main objects of my anatomical and systematic work on the Oligochæta are (1) the tracing out of the course of evolution within the group—certain families, for example, the Megascolecidæ, allow lines of descent to be traced within them with more and more certainty as our knowledge of the anatomy and distribution of their members increases , (2) to contribute to the science of palæogeography by means of an increasingly accurate knowledge of the earthworm faunas of the several regions of the globe Since earth worms for the most part spread only by their own slow progression in the ground, to a life in which they are absolutely confined, a knowledge of the distribution of the various genera affords valuable material for determining the configuration of the land in former epochs

Societies and Academies

LONDON

Royal Society, Jan 22 —P M S Blackett and F C. Champion The scattering of slow α particles in helium Mott has calculated the scattering of α particles by helium atoms on the assumption that the particles interact according to the inverse square law, that they have no nuclear spin and that they obey the Einstein Bose statistics It is found that the scattering should vary periodically with changing angle and velocity in fact an interference pattern should be obtained the scale of which depends on the velocity This theory has been tested by photographing the collisions between slow α particles and helium atoms in a Wilson chamber The results are in complete agreement with Mott s theory —W A Bone, R P Fraser, and F Lake Explosions of mixtures of acetylene and electrolytic gas The disturbing influence of successive additions of acetylene upon the uniformity of the initial flame movement in an explosion of electrolytic gas attains a maximum when 20 per cent of acetylene is present in the medium, thereafter declining and eventually disappearing when 30 per cent of acetylene is present There is a primary selective partial combustion of acetylene, $C_2H_2 + O_2 = 2CO + H_2$ in the flame front followed, behind the flame front by either (i) when sufficient oxygen is present a highly luminous combustion of the nascent carbon monoxide or (ii) otherwise by a thermal decomposition of any unburnt acetylene The explosion of a $C_2H_2 + O_2 + 2H_2$ mixture is differently affected by an equal dilution with argon or nitrogen —W A Bone and R P Fraser Flame speeds in the inflammation and detonation of CO O_2 mixtures In the initial phase of inflammation , and in the final stage of detonation , the maximum flame speed for moist mixtures at atmospheric pressure is obtained with a *circa* $3CO + O_2$ instead of a theoretical $2CO + O_2$ mixture Dilution of the medium with either argon helium or nitrogen does not materially alter the proportions of carbonic oxide and oxygen in the maximum speed mixture Hence the point of maximum flame speed is principally determined by the concentration of carbon monoxide and the combustion of moist carbonic oxide is conditioned by a prior excitation of its molecules, which are then rendered combustible —C V Jackson Interferometric measurements in the arc spectrum of iron Ten lines in the spectrum of the iron arc in air, between $\lambda 4000$ and $\lambda 4400$ have been measured by interferometric comparison with the red line of cadmium or with the secondary standards of neon Sixty eight lines in the spectrum of the iron arc in air between $\lambda 2300$ and $\lambda 3100$ have also been measured interferometrically The results are in good accord with the wave lengths recommended by the International Astronomical Union in 1928

EDINBURGH

Royal Society, Jan 12 —J W Gregory The Dalradian rocks of Scotland and the structure of the Southern Highlands The Dalradian rocks can be traced across the Southern Highlands of Scotland from Argyll to the Moray Firth and the coast south of Aberdeen The author in 1910 rejected the

generally accepted conclusion that the oldest Dalradian rocks outcrop along the southern border of the Highlands, and that there is an ascending series to the Moine gneiss to the north He regards the slates and grits to the south as a younger but still pre Palæozoic series (the Lennoxian), and as composed of Dalradian debris, the Dalradian band as consisting of five series, with the youngest to the north, and the Dalradian beds as having been deposited on the southern flank of a land composed of the Moine The evidence for these conclusions is submitted in detail The author regards the beds as in their original order, except where locally inverted as in Ben Lui and near Callander He correlates the north eastern Dalradian and Lennoxian rocks south of the Moray Firth with those of Perthshire and south west Scotland, from which they are separated by the granites of the Cairngorms and western Aberdeenshire —**J Weir** The British and Belgian Carboniferous Bellerophontidæ Eighty two forms are discussed under nine genera The Bellerophontid faunas of various horizons and facies are tabulated and discussed, and attention is directed to assemblages of stratigraphical value in the Scottish Carboniferous succession and equivalent rocks in the north of England, with special reference to stages in the evolution of *Euphemus urei*, *Bucaniopsis decussatus*, and *Tropidocyclus oldhami* —**Elsie J Cadman** Life history of *Didymium nigripes* *Didymium nigripes* is a species belonging to the slime fungi or Mycetozoa found growing on germinating beet 'seeds', and it also grows frequently on dead leaves of many kinds The spores germinate readily, each spore giving rise to two swarm cells, because germination is preceded by a division within the spore coat At the division four chromosomes are present, and there are distinct centrosomes After several divisions the swarm cells withdraw their flagella and become transformed into myxamœbæ The myxamœba possesses no flagellum and no bleparoplast and cannot become a swarm cell again They fuse in pairs to form zygotes A plasmodium which may be slightly bigger than those in its neighbourhood, either because it possesses a great number of nuclei or has engulfed a larger number of myxamœbæ, can exert some form of attraction on the smaller plasmodia around it, and they coalesce with it in large numbers A large plasmodium, therefore, rapidly increases in size, and continues to do so by coalescing with the smaller plasmodia in its neighbourhood Chromosome numbers were fully investigated —**R Crookall** The genus *Lyginorachis* Kidston This genus was instituted by the late R Kidston, of Stirling, to include petrified leaf stalks with a structure similar to that of the well known Coal Measure plant *Lyginopteris oldhamia* Though Kidston recognised and named two species of *Lyginorachis*, he described neither In his admirable "Studies in Fossil Botany", Dr D H Scott described, but did not figure, *L papilio* from the Cementstone Group (Calciferous Sandstone Series) of Norham Bridge, Tweedside The second species was appropriately named by Kidston *Lyginorachis taitiana* It was referred to, but not described, by Dr Scott Fortunately, Kidston had prepared excellent photomicrographs of both forms, and these are used to illustrate the paper —**J Geronimus** Some problems involving the persymmetric determinants

ROME

Royal National Academy of the Lincei Communications received during the vacation —**F Enriques** Algebraic surfaces —**G Barba** Generalised parallelism —**F Odone** Rotation and divergence of a vector, gradients of a homograph in general curvilinear coordinates —**Maria Pastori** Further on the partial derivation of tensors —**P Cattaneo** A class of cyclic varieties —**M G Bouligand** General expression for the solidarity between the problem of the minimum of an integral and the corresponding Hamilton-Jacobi equation —**G Andreoli** Pseudo-limits of functions, pseudo continuity, etc —**M Manarini**: Lines of curvature and geodetics of a surface —**S Finikoff** The "suites" of M Fubini —**G Bozza** Action of certain apparatus for blowing gases —**G A Barbieri** Complex thiocyanates of quadrivalent molybdenum Various difficulties are encountered in the preparation of these compounds, but a number of them have now been obtained by carefully oxidising the corresponding tervalent molybdenum derivatives by means of potassium ferricyanide —**Giambattista Dal Piaz** New genera and new species of artiodactyls in the Venetian oligocene Investigation of the numerous fossil artiodactyls of the Basle Museum indicates that the genus *Anthracochœrus* occupies a completely isolated systematic position and shows a tendency to diverge from the complex type of *Anthracotheridæ* and to approach in some respects that of certain primitive *Suidæ* It is concluded that the Monteviale artiodactyl is not related to any of the numerous phylogenetic lines of the *Anthracotheridæ*, but represents a type of which neither the eocene ancestors nor any oligocene successors are known —**G Brunelli** Monotonous rotifer planktons in an elevated Apennine lake The plankton of Lake Scanno consists mainly of *Cyclops strenuus* Fischer and of large masses of the rotifer *Asplanchna priodonta* Gosse —**Teodoro Perri** Behaviour of the optical vesicle of *Triton* grafted into embryos of *Rana esculenta* (Destruction and power of recovery) —**Giulio Cotronei** and **Aldo Spirito** Zoological constitution and grafts New experiments between Anura and Urodela (4) —**G Mezzadroli** and **E Vareton** Action exerted by radium on the germination of seeds Experiments in which barley, wheat, peas, and beans were subjected to the influence of the γ rays of radium show that the effect of a short exposure on the germination of the seeds is beneficial and that of a long one injurious When 3 9 mgm of radium was used, benefit became appreciably apparent after 5 minutes and reached a maximum after 30 minutes With one half of this amount of radium, the exposure must be quintupled The best result obtained consisted of increases of 30 per cent in the number of seeds germinated, 80 per cent in the total height, and 80 per cent in the weight of the plants The stimulating effect is still active two months after the irradiation

SYDNEY

Royal Society of New South Wales, Oct 1 —**H G Roggatt** Thrust faults and compression joints in the Muree beds, near Grasstree, New South Wales The beds in which the faults and joints occur, consist of sandstone and conglomerate—competent rocks—overlain and underlain by shale and mudstone—incompetent rocks—constituting an ideal series for the development of compression phenomena Stress in a sandstone member is expressed by sharply defined faults which pass upward into conglomerate as monoclinal or slightly overturned folds These thrust faults are inclined to the horizontal at an angle of about 30° Joints are developed in two sets, one parallel to the faults and one inclined thereto at 120° The fractures appear to obey Mohr's theory of rupture and furnish striking practical confirmation of Hartmann's law Since the direction of thrust is known, the orientation of the strain ellipsoid is known, showing that the axis of maximum compression lies in the *acute* angle between the shear planes Experimental determination of the angle of friction of the sandstone confirms

the view that the principal factor tending to reduce the fracture angle to less than 45° is the internal friction of the rock itself —**A J Matheson** The geology of the Wellington district, N S W, with special reference to the origin of the Upper Devonian Series The oldest rocks are of Silurian age, comprising shales and limestones in which are interbedded a great volcanic series The limestone occurs on two horizons and both are coralline, the upper limestone is the more highly fossiliferous and is the youngest of the Silurian rocks It passes by a gradation through an arenaceous type into a calcareous sandstone and, finally, into sandstone itself, the sandstone series, in its upper part, contains *Lepidodendron Australe* and *Spirifer disjunctus*, and is, therefore, of Upper Devonian age Sandstones are characteristically red in colour, and it is suggested that they were deposited under arid conditions They are intruded by the Wuuluman granite —**G F K Naylor** The history of the development of the present drainage system in the Marulan district Theories involving river capture were advanced by Andrews in 1904 and by Woolnough and Taylor in 1906 Andrews suggested that the old Shoalhaven was beheaded by a tributary of the Hawkesbury, while the other writers postulated an old Wollondilly beheaded by a newly formed coastal stream The theory now being put forward suggests that the present Shoalhaven Kangaroo system originally flowed in a westerly direction away from the coast, in a manner analogous to the present Upper Nepean system Capture and reversal by a coastal stream which developed as a result of the post Tertiary uplift is regarded as having brought about the present river distribution —**A R Penfold** and **F R Morrison** Notes on the essential oils from some cultivated Eucalypts (2) The species consisted of *E Australiana*, *E Macarthuri*, *E citriodora*, *E Smithii*, *E dives*, and *E dives* variety 'A' and variety 'B' Leaves from the trees of an avenue of *E bicostata*, near Sydney, show considerable variation in size and shape although grown from the seed of one tree collected at Jenolan, New South Wales The yield of oil varied from 1 23 to 2 4 per cent and the cineol content from 38 to 65 per cent The species is really a form of *E globulus* confined to the mainland of Australia and should have been named *Eucalyptus globulus* variety *bicostata* The chemical constituents of the oil are similar to those of *E globulus*, namely, isovaleric aldehyde, *d* α pinene, cineol, eudesmol, etc

Diary of Societies

FRIDAY, JANUARY 30

ROYAL COLLEGE OF SURGEONS OF ENGLAND at 5 —Dr D Hunter Changes in the Bones in Hyperparathyroidism and Hyperthyroidism

INSTITUTION OF ELECTRICAL ENGINEERS (West Wales (Swansea) Sub Centre) (at Corporation Electricity Showrooms Swansea), at 6 —J Urmston The Electrical High Pressure Testing of Cables and the Localisation of Faults

NORTH EAST COAST INSTITUTION OF ENGINEERS AND SHIPBUILDERS (at Mining Institute Newcastle upon Tyne), at 6 —C F Christensen The Whaling Factory Ship *Vikingen*, with Some Notes on Whaling

JUNIOR INSTITUTION OF ENGINEERS (Informal Meeting), at 7 30 —W Fish Modern Methods of Production of Small Machined Work

ROYAL INSTITUTION OF GREAT BRITAIN at 9 —Prof G M Trevelyan The First Defence of Gibraltar by the English, Oct 1704–April 1705

ROYAL AERONAUTICAL SOCIETY (Hull and Leeds Branch).—Col the Master of Sempill Gliding and Soaring

SOCIETY OF DYERS AND COLOURISTS (Scottish Section) —D K Colledge Dyeing for the Scottish Tweed Trade

MANCHESTER LITERARY AND PHILOSOPHICAL SOCIETY (Chemical Section)

SATURDAY, JANUARY 31

BRITISH MYCOLOGICAL SOCIETY (in Botanical Department University College) at 11 A M —*Dr A S Horne* (*a*) *Nuclear Division in Spongospora* (*b*) Preliminary Study of the Fungus Flora of the Air —N M Nitimargi Factors Influencing Spore Formation —L N Seth Factors Influencing Fungal Growth —W C Moore and Dr A Smith Notes on Some Interesting Fungi Recently Recorded —A A Pearson A Fungus Foray in Spain

MATHEMATICAL ASSOCIATION (at *Bedford College for Women*), at 3 —Annual Meeting

ROYAL INSTITUTION OF GREAT BRITAIN, at 3 —Dr E Cammaerts Flemish Art (2) Breughel

MONDAY, FEBRUARY 2

ROYAL SOCIETY, EDINBURGH, at 4 30 —Sir E A Sharpey Schafer Observations on the Relative Rate of Growth of the Nails of the Right and Left Hands respectively on Seasonal Variations in the Rate, and on the Influence of Nerve Section upon it —Dr F J W Whipple A Note on the Secular Changes of Rock Temperature on the Calton Hill —*To be read by title* —Prof E L Ince Zeros and Turning Points of the Elliptic Cylinders

ROYAL COLLEGE OF SURGEONS OF ENGLAND, at 5 —H. H Woollard The Potency of the Pharyngeal Entoderm

ROYAL INSTITUTION OF GREAT BRITAIN at 5 —General Meeting

SOCIETY OF ENGINEERS (at Geological Society), at 6 —H W Towse Presidential Address

INSTITUTION OF ELECTRICAL ENGINEERS (Western Centre) (at Cardiff), at 7 —D B Hoseason The Cooling of Electrical Machines.
ROYAL INSTITUTE OF BRITISH ARCHITECTS, at 8 —Prof W Rothenstein The Decoration of Buildings
ROYAL SOCIETY OF ARTS, at 8 —Prof L. C Martin Some Modern Developments in Microscopy (Cantor Lectures) (2).
SOCIETY OF CHEMICAL INDUSTRY (London Section) (jointly with Faraday Society and Chemical Engineering Group) (at Chemical Society), at 8 —Dr E B Maxted The Specific Activity of Catalysts —Prof E K Rideal Specific Catalytic Surfaces.
BRITISH PSYCHOLOGICAL SOCIETY (Education Section) (at London Day Training College), at 8 30 —Miss Ella Freeman Sharpe Sublimation A Correlation between the Experiences of an Educator and Psychoanalyst.

TUESDAY, FEBRUARY 3

ROYAL INSTITUTION OF GREAT BRITAIN, at 5 15 —Dr J W T Walsh The Art of Illumination (3).
ZOOLOGICAL SOCIETY OF LONDON, at 5 30 —Dr Nellie B Eales The Development of the Mandible in the Elephant —A. D Middleton A Contribution to the Biology of the Common Shrew (*Sorex araneus* Linn).—F C Baker The Classification of the Large Planorboid Snails of Europe and America —S Maulik On the Larva of the Poisonous Chrysomelid Beetle of N gamiland, Africa —Dr C Crossland The Reduced Building Power and the Variations in the Astrean Corals of Tahiti with a Note on *Herpetolitha limax* and *Fungia* sp — Dr Marie V Lebour (*a*) Further Notes on Larval Brachyura (*b*) The Larvæ of the Plymouth Caridea I The Larvæ of the Crangonidæ II The Larvæ of the Hippolytidæ
INSTITUTE OF METALS (Birmingham Section) (at Chamber of Commerce Birmingham), at 7 —C E Moore, I A Bailey, and others Discussion on Refractories
ROYAL PHOTOGRAPHIC SOCIETY OF GREAT BRITAIN, at 7 —F Judge Some Early Experiments in Colour Photography
INSTITUTION OF AUTOMOBILE ENGINEERS (at Royal Society of Arts), at 7 45 —Dr W H Hatfield Rustless Steels as applied to Automobiles and Aircraft.
ROYAL ANTHROPOLOGICAL INSTITUTE, at 8 30 —Prof M Herskovits The New World Negro as an Anthropological Problem

WEDNESDAY, FEBRUARY 4

ROYAL COLLEGE OF SURGEONS OF ENGLAND, at 5 —T P Dunhill Malignant Disease of the Thyroid Gland—the Relation of the Incidence and Spread to its Embryology and Prognosis
INSTITUTION OF ELECTRICAL ENGINEERS (Wireless Section), at 6 —P K Turner Some Measurements of a Loud Speaker *in vacuo*
SOCIETY OF PUBLIC ANALYSTS AND OTHER ANALYTICAL CHEMISTS (at Chemical Society) at 8 —Dr L. H Lampitt and J H Bushill Some Factors affecting the Solubility of Milk Powder —S Marks and Dr R S Morrell (*a*) The Determination of the Hydroxyl Content of Organic Compounds Estimation of Castor Oil (*b*) The Determination of the Carbonyl and Aldehyde Content of Organic Compounds Estimation of Phenylhydrazine —Dr A van Raalte and J Straub Food Control in Holland —H R Ambler The Determination of Small Quantities of Methane —R. Bhattacharya and Dr T P Hilditch The Fatty Acids and Component Glycerides of Indian Ghee
ROYAL SOCIETY OF ARTS at 8 —C Le Maistre The Effect of Standardisation on Engineering Progress.
ROYAL SOCIETY OF MEDICINE (Surgery and Pathology Sections), at 8.30 —V Z Cope and P H Mitchiner (Surgery), Dr A Fleming and Dr T H C Benians (Pathology) Special Discussion on Indications for and the Value of the Intravenous Use of Germicides
ROYAL MICROSCOPICAL SOCIETY (Biological Section) (in B M A House Tavistock Square).

THURSDAY, FEBRUARY 5

ROYAL SOCIETY at 4 30 —C F Jenkin The Pressure Exerted by Granular Material —F L. Arnot The Diffraction of Electrons in Mercury Vapour S Rama Swamy On the Transmission of Light by Thin Films of Metal —*Papers to be read in title only* —S Goldstein The Forces on a Solid Body Moving through Viscous Fluid (Notes by J M Burgers).—D C Colbourne The Diurnal Tide in an Ocean Bounded by Two Meridians
LINNEAN SOCIETY OF LONDON, at 5 —Dr M Bernhauer and Dr H Scott Abyssinian Staphylinidæ —S Savage On a Recently discovered Letter from Linnæus dated 1750 —I H. Burkill Photographs of *Dioscorea esculenta* taken in Siam by Dr A F G Kerr — Dr T A Sprague and C V B Marquand The New Flora of Gore Cliff Landslide
LONDON MATHEMATICAL SOCIETY (at Royal Astronomical Society), at 5 — Prof G N Watson Ramanujan s Note Books (Lecture).
ROYAL INSTITUTION OF GREAT BRITAIN at 5 15.—Prof H Dingle The Nature and Scope of Physical Science (3).
BRITISH ASSOCIATION OF REFRIGERATION (at Institution of Mechanical Engineers), at 5 30 —Dr Ezer Griffiths Some Instruments for Refrigeration Work
INSTITUTION OF ELECTRICAL ENGINEERS at 6.—P J Ryle Two Transmission Line Problems Suspension Insulators for Industrial Areas in Great Britain , Conductor Vibration
INSTITUTE OF CHEMISTRY (Manchester Section) (at " Manchester, Ltd , Manchester) at 7 —Prof F L Pyman Paper
SOCIETY OF CHEMICAL INDUSTRY (Bristol Section) (jointly with Institute of Fuel) (at Bristol University), at 7 30 —M H Lewis Recent Development in the Economic Production of Steam from Factory Boiler Plants.
SOCIETY OF CHEMICAL INDUSTRY (South Wales Section) (jointly with South Wales Section of Institute of Chemistry and Microscopical Society of Wales) (at Cardiff Technical College), at 7 30.—C A. Seyler The Microstructure of Coal
CHEMICAL SOCIETY, at 8 —J W Baker Salt-forming Characteristics of Doubly and Singly Linked Elements of the Oxygen Group Part I The Carbonyl Group in Benzaldehyde and Acetophenone.—J W Baker and W G Moffitt Salt-forming Characteristics of Doubly and Singly Linked Elements of the Oxygen Group. Part II The Nitration of Benzaldehyde and Acetophenone in Sulphuric Acid Solution. —Prof T M Lowry and G Jessop The Properties of the Chlorides of Sulphur Part V Metastable States.—J W Cook (*a*) Polycyclic Aromatic Hydrocarbons Part II The Non-existence of 1 2 7 8-dibenzanthracene (*b*) Part III Derivatives of 1 2 5 6-dibenzanthracene , (*c*) Part IV Condensed Derivatives of 1 2 benzanthracene.
ROYAL SOCIETY OF MEDICINE (Tropical Diseases and Parasitology and Disease in Children Sections), at 8.—Dr A Castellani and Dr G W Bray (Tropical Diseases), Dr A. R. Neligan and Dr H S Stannus (Disease in Children) Special Discussion on The Adaptation of European Women and Children to Tropical Climates.

FRIDAY, FEBRUARY 6.

ROYAL SOCIETY OF MEDICINE (Otology Section), at 10 30 A.M —Sir St. Clair Thomson, F C Ormerod, and others Discussion on Tuberculosis of the Ear
ROYAL ASTRONOMICAL SOCIETY (Geophysical Discussion), at 4 30.—The Escape of Radiation from the Atmosphere Chairman, Sir Gilbert Walker Opener, Dr G C Simpson, followed by Sir Napier Shaw, Dr F J W Whipple, and Prof E A Milne
ROYAL SOCIETY OF MEDICINE (Laryngology Section), at 4 30 —Discussion on The Treatment of Frontal Sinusitis.
PHYSICAL SOCIETY (at Imperial College of Science and Technology), at 5 —H E Beckett The Radiation Reflecting Powers of Rough Surfaces —E B Moss A Ballistic Recorder for Small Electric Currents.—F J Scrase The Instrumental Phase Difference of Seismograph Records.—Demonstrations by G L. Addenbrooke
SOCIETY OF CHEMICAL INDUSTRY (Manchester Section) (jointly with Manchester Section of Institution of the Rubber Industry) (at Engineers Club, Manchester), at 7 —A Fraser Plant Used in the Manufacture of Synthetic Resins —Dr E E Walker and E A Bevan The Effect of Certain Factors upon the Electrical Properties of Moulding Powder and Synthetic Resins.
INSTITUTION OF ELECTRICAL ENGINEERS (Meter and Instrument Section), at 7 —R. Davis G W Bowdler and W G Standring The Measurement of High Voltages, with special reference to the Measurement of Peak Voltages —Dr L E Ryall The Construction and Operation of a Simple Neon Tube High Tension Crest Voltmeter —S Whitehead and A P Castellain Sphere-Gap Calibration
INSTITUTION OF ELECTRICAL ENGINEERS (North Eastern Centre) (at Literary and Philosophical Society, Newcastle-upon Tyne), at 7 — Prof W Cramp The Birth of Electrical Engineering (Faraday Lecture).
OIL AND COLOUR CHEMISTS ASSOCIATION (Manchester Section) (at Milton Hall Manchester) at 7 —Members Evening
ROYAL PHOTOGRAPHIC SOCIETY OF GREAT BRITAIN (Pictorial Group) at 7 —Informal Meeting
JUNIOR INSTITUTION OF ENGINEERS (Informal Meeting), at 7 30.—J W White Aerial Wire Ropeways
GEOLOGISTS ASSOCIATION (in Botany Theatre University College) (Annual General Meeting), at 7 30 —Prof W W Watts Bournes (Presidential Address)
ROYAL INSTITUTION OF GREAT BRITAIN, at 9 —J M Keynes The Internal Mechanics of the Trade Slump.

SATURDAY, FEBRUARY 7

ROYAL INSTITUTION OF GREAT BRITAIN, at 3 —Dr E Cammaerts Flemish Art (3) Rubens

PUBLIC LECTURES.

SATURDAY, JANUARY 31

HORNIMAN MUSEUM (Forest Hill), at 3 30 —Miss M A Murray Most Ancient Egypt

MONDAY, FEBRUARY 2

LONDON SCHOOL OF HYGIENE AND TROPICAL MEDICINE (Public Health Division), at 5 —J C Dawes Public Cleansing The Disposal of House and Trade Refuse

TUESDAY, FEBRUARY 3

LONDON SCHOOL OF HYGIENE AND TROPICAL MEDICINE, at 5 —Dr P Manson Bahr The Dawn of Tropical Medicine, being an Account of the Life and Work of Sir Patrick Manson
UNIVERSITY COLLEGE HOSPITAL MEDICAL SCHOOL, at 5 15.—Dr W Cramer Filterable Tumours (Succeeding Lecture on Feb 10)

WEDNESDAY, FEBRUARY 4

LONDON SCHOOL OF HYGIENE AND TROPICAL MEDICINE (Public Health Division), at 5 —Dr W G Savage Food Poisoning
IMPERIAL COLLEGE OF SCIENCE AND TECHNOLOGY, at 5 30 —Prof C G Darwin The Foundations of Atomic Mechanics. (Succeeding Lectures on Feb 5 and 6)
KING S COLLEGE, LONDON, at 5 30 —Prof A P Newton The Great Age of Discovery (3) Christopher Columbus and his Rivals
BELFAST MUSEUM AND ART GALLERY, at 8.—E Godfrey Brown Wind Instruments.

THURSDAY, FEBRUARY 5.

KING S COLLEGE, LONDON, at 8.—C J Gadd Babylonian Religion
BEDFORD COLLEGE FOR WOMEN, at 5 15.—Lady Chatterjee Indian Labour Problems.

SATURDAY, FEBRUARY 7

GILBERT WHITE FELLOWSHIP (at 6 Queen Square, W C 1), at 3.—Prof E . Salisbury Some Rarer British Plants and their Distribution
HORNIMAN MUSEUM (Forest Hill), at 3 30.—Dr F A Bather The Cuttle Fish and its Ancestors.

SATURDAY, FEBRUARY 7, 1931

International Health

THE report on the Health Organisation of the League of Nations adopted by the last Assembly noted the success which international co-operation can achieve in technical matters Co-operation in health matters is indeed relatively easy there are few, if any, vested interests comparable with those which hinder progress in the economic or political fields Health administrators, in recognising the essential similarity of health problems in different countries and in different areas, and the value to all of the experience of particular administrations, have come to recognise also the responsibility of co operation and of placing at the disposal of all the special information and experience which some have gained

The success of international as well as of national health work is, however, so closely connected with economic, financial, and social conditions that to select only one of these factors for study and action would be to invite failure Such considerations alone would suffice to connect the work of the Health Organisation with the main stream of international co operation which is developing through the League of Nations

At a recent session of the Health Committee, Dr Madsen, Director of the Danish State Serum Institute, who has been chairman of the Committee since its foundation, submitted a memorandum reviewing the present position of the Health Organisation in the light of its ten years' work and suggesting the lines of future development The very success of this form of international co-operation, and the fact that certain branches of the work are tending to assume a permanent character, make it highly desirable that the work of the Health Organisation should be directed along generally approved lines of policy

The study and collection of information is a branch of activity of which the Singapore Epidemiological Intelligence Bureau and the compilation of public health statistics are outstanding examples, and represents a phase through which every branch of the League's health activities, including even the activities of its Epidemic Commission in Poland in 1920, has to pass

Investigations lead in due course to the formation of general opinions and the elaboration of certain principles and recommendations for action The work of the Permanent Standardisation Commission in establishing and maintaining uniform international standards and methods of testing for serological and biological products is an example of

this stage, which is tending to assume permanency because such work must be continuous in order to keep in touch with developments of scientific technique and thought Similarly, the lengthy regional studies carried out by the Malaria Commission in Russia, south eastern Europe, the Mediterranean countries, and in India, as well as in the Mississippi basin, have led to an agreed general programme of anti malaria measures, while the plans for epidemiological study and administrative action which are now under discussion will require at least three years to complete The Sleeping Sickness Commission has already made some progress in the study of a disease which has hitherto defied the independent national efforts of African administrations, but a considerable period of international study and co operation will undoubtedly be required before sleeping sickness can be brought under adequate control in tropical Africa The Leprosy Commission, after a preliminary world survey of leprosy conditions, has, however, only just commenced its real work, and even certain partial studies, such as those on scarlet fever and diphtheria, are yet incomplete

Such scientific work and the continuous liaison work with health administrations, notably the system of interchanges or study tours for public health officers, are, of course, the main feature of the work of the Organisation Their development must inevitably tend to stress the third stage of activity of the Organisation, the initiation of action upon the lines indicated by the data obtained

Primarily, of course, action is a matter for the individual health administrations, but in recent months the Governments of Greece, Bolivia, Bulgaria, and China have all sought the technical advice and assistance of the League Health Organisation in elaborating plans or policies for health reconstruction work One of the chief developments of the Health Committee's work will undoubtedly lie in its collaboration with Governments seeking technical advice, and in the elaboration of a suitable administrative and medical technique

The advisory opinions given in this way represent essentially a declaration of the present state of knowledge and practice in particular fields of public health They are based on the pooled knowledge and experience of leaders in public health and medical research, and are, as Dr Madsen points out, needed in a number of fields of investigation at the present time Notably this is true in regard to maternal and infant welfare The infant mortality inquiry has led to the collection of a large amount of information, and a general report on the subject would be invaluable, not only to the South American States who extended the scope of inquiry at the Monte Video conference, but also to other countries anxious to organise national campaigns against infant and maternal mortality

Here, as in the case of such social diseases as cancer, rheumatic fever, heart disease, against which sanitary administrations have been compelled to take action in the last two decades, an analysis of the reasons which have led different countries to adopt specific measures, the determination of the degree of agreement existing on such measures and of the points where diversity of practice suggests further investigation, would be of very material assistance A series of reports of this type, properly prepared, would set out in detail the modern practice of preventive medicine and should furnish a basis for the study of the relations between public health services and health insurance

Similarly, the survey of medical schools and education in which the Organisation is assisting in China is another field which cannot be omitted from the programme of the Committee, if its studies of public health conditions are to be complete, and this is notably true in regard to Colonial administration

The growth and success of the International Health Organisation are of outstanding interest to all who are concerned with scientific progress The Organisation represents a definite advance in international scientific co-operation There seems to be no inherent obstacle to the development of international co-operation along similar lines by other scientific workers There are, indeed, indications that this is a most hopeful line of advance by which scientific workers can assume their responsibilities of leadership An international scientific organisation, as the experience of the Health Organisation demonstrates, is able to express a technical or scientific opinion which is too important to be disregarded and accordingly receives due consideration with the economic, financial, social, or political factors involved

The lack of administrators qualified to evaluate scientific as well as other factors involved in social, political, and economic problems has been responsible for many of society's most acute problems to-day, and has not been without effect upon the course of the rationalisation movement in industry It is at least possible that the development of international co-operation of the character represented by the League's Health Organisation may assist in the production of this much needed type of administrator

The Significance of the Seventeenth Century.

The Seventeenth Century By G N Clark Pp xii + 372 (Oxford: Clarendon Press, London Oxford University Press, 1929) 15s net

THOSE who remember the brilliant chapter by Prof Whitehead on "The First Physical Synthesis", in "Science and Civilization" (Unity Series), will rejoice greatly in Mr G N Clark's volume Prof Whitehead said that 1642, the year of the death of Galileo and the birth of Newton, was one of the crucial points in the history of mankind It marked "the centre of that period of about 100 years during which the scientific intellect of Europe was framing the synthesis which has remained down to our own times the basis of science Our modern civilization is due to the fact that in the year when Galileo died, Newton was born Think for a moment of the possible course of history supposing that the life's work of these two men were absent "

Now Mr Clark, without labouring the point or even expressly announcing it—for he does not seem to have noticed the striking coincidence of the dates—yet manages to provide, in a masterly survey of the whole field, abundant and conclusive evidence of the truth of Whitehead's remark On all sides of life in the Western world the seventeenth century saw the growth of the new spirit of inquiry, observation, synthesis, and, above all, measurement, which are the marks of science and of which Galileo and Newton were the greatest exemplars The great personal interest of Mr Clark's book lies in the fact that he comes to this conclusion without *parti pris*, as a professional historian trained rather on literary than scientific lines, but with an open mind and a supreme impartiality His book surveys the century from all points of view under topics, and without the accustomed political framework Politics and literature, of course, find their place, but only as two of twenty main subjects into which the matter is divided One might have thought that this would render reading less easy, but it is not the case The style and the selection and arrangement of the matter are so good that interest never flags

The chapters on science, philosophy, and other more specially intellectual things, do not take the first place, but we are led up to them through an account of the population, industries, constitutions, armies, navies, and colonies of the nations of Europe Then, near the end of the book, we reach the characteristic and most active force of the age, the scientific mind There is no attempt to press the connexion unduly or over-simplify the problem, but we see the same awakened intellect which in the outlying departments of practical life was ordering the national States, regularising armies, arranging postal services, and measuring and counting political and social facts, engaged at the centre in the supreme philosophic task of putting together the facts of the universe Undoubtedly, all these things are interconnected, and Mr Clark often shows the same man engaged both in purely abstract and in practical work, as Newton in the Mint or Grotius as ambassador What is so refreshing about his presentation is the attempt to give the whole in a manageable shape, allowing the salient points to appear above the details Of these points, two are most obvious, science and organisation We have spoken of the former, the latter is equally pervasive

The seventeenth century first made prominent in the West the tendency to knit society together, first nationally and then internationally, after the dispersive effects of feudalism and the religious wars of the sixteenth century Collective thought and action are the pre-eminent human qualities, and, on a certain plane and with certain intellectual presumptions, the Catholic Church had been achieving unity for many generations From the fourteenth century onwards, however, this work had been done more and more feebly and was at last completely interrupted The independent national sovereign States then began to take it up in a more drastic and comprehensive way Each State began to bring together, organise, and regulate the lives of its citizens with a thoroughness which an international Church had never been able to secure

Mr Clark exhibits for us the various spheres in which this activity was exercised by monarchs who, for this time and this purpose, needed to be practically absolute Hence arise the new and increasing standing armies, the organisation of government posts, the regulation of industry, the control of religion and education But, although the direction was largely governmental, it was by no means entirely so, and less in England and Holland than in other countries Combined effort of a more spontaneous kind was also a feature of the times, which saw the rise of joint stock companies and the great trading companies for exploitation abroad, such as the East India Company and a host of others, mainly English, French, and Dutch Though these and other activities were at that time and long after mainly national and aggressive towards other nations, we may trace the beginnings

of combination between nations in such spheres as diplomacy and international law, while, as Mr Clark reminds us, the end of the century witnessed the first definite joint consciousness of the West as against Turkey and the East since the Crusades

The eighteenth and nineteenth centuries were to see both these movements worked out to their logical conclusion First England and France and then England and Germany were to fight to the point of exhaustion for colonies and maritime supremacy, while the forces of co operation were gathering strength behind the scenes Our own times have seen the tragic outcome of the first process and the final apotheosis of the second

Mr Clark has not written with any propaganda in his mind, and for that reason the moral shines out the more clearly from his pages Readers of this review will turn with special pleasure to those parts of his book where he describes the beginnings of the apparatus which was ultimately to re-establish the broken contacts of the Middle Ages and make them stronger and more universal They will remember with gratitude that it was a man of the seventeenth century, Huygens the Dutchman, at home both in Paris and London, who gave as his English motto, "The world is my country, to promote science my religion" F S MARVIN

American Coal Mining

Transactions of the American Institute of Mining and Metallurgical Engineers (Incorporated) Coal Division, 1930 containing Papers and Discussions presented at Meetings held in New York, February 1928, February 1929, and February 1930 Pp 724 (New York American Institute of Mining and Metallurgical Engineers, Incorporated, 1930) 5 dollars net

THE American Institute of Mining and Metallurgical Engineers is one of the most important learned societies in the United States, and its *Transactions* have for many years taken very high rank amongst the world's technical publications Until quite recently, the *Transactions* took the form of one or two annual volumes, covering all branches of mining and allied technology, but recently a system has been introduced of collecting all papers dealing with one specific branch of the subject into one volume and publishing this by itself The present volume is the first volume of this kind, dealing exclusively with coal mining, and is the outcome of the papers and discussions presented during the years 1928, 1929, and the early part of 1930

It is quite natural that with the increase of complexity which characterises modern methods in nearly every subject, increased specialisation has become necessary, one outcome of such specialisation is the subdivision of the *Transactions* of the American Institute of Mining and Metallurgical Engineers into a number of separate divisions This system has its drawbacks as well as its advantages In the older volumes were to be found papers dealing with every branch of the whole wide subject, and an engineer interested in one section only, who turned over the volume to find papers on his special branch, could scarcely help seeing the others, he might even be induced to read them, and would probably find that every paper, however remote its subject might appear to be from the particular subject upon which he was engaged, would, nevertheless, throw some new light upon it and prove of some assistance to him This advantage he now loses under the new method His knowledge of the individual subject may, no doubt, become more profound than it was, but he necessarily loses that breadth of outlook which is one of the most valuable qualities that an engineer can cultivate

Persistence in the method symbolised by the volume now before us would undoubtedly lead gradually to the separation of coal mining from metalliferous mining, a separation from which engineers in Great Britain have suffered for long, owing in their case to statutory requirements The result has been that in Great Britain coal mining engineers were, generally speaking, ignorant of what was being done in metal mining, and vice versa, and appliances devised for use in one branch of the industry might remain for years unknown to the other, although it would be quite capable of finding useful application therein A case in point is the use of tables of the Wilfley type, devised originally for the dressing of ores in a relatively fine state of division Such tables have proved to be equally useful for the cleaning of small coal, but it was many years before British coal mining engineers learnt anything about the capabilities of such tables and attempted to apply them to coal mining needs

The volume under notice gives a useful epitome of the coal mining problems to-day in the United States and of the methods adopted for solving them There are, in all, some forty four papers, ten deal with coal mining, covering such subjects as ventilation, subsidence, and misfires, there are four papers on coal cleaning, three papers on coking, some nineteen papers on the classification

of coal, and a number of miscellaneous papers, including several which deal more especially with the methods of coal analysis It will be seen at once that the field covered is a wide one, and that the information contained in this volume is likely to be of great value to all coal miners, not only in the United States but also in Great Britain

We in Great Britain have already learnt a great deal from our coal mining friends in the United States, especially in matters relating to the mechanisation of collieries and the replacement of manual labour by mechanical appliances In the present serious condition of the British coal mining industry, it is quite evident that we shall necessarily have to progress much further along the same road, and British coal mining engineers will no doubt welcome the opportunity which this volume affords of learning how American coal miners are attacking problems which, after all, are more or less the same for both countries, although, having regard to the differences in natural conditions, they can never be quite identical In Great Britain, where, as already pointed out, coal mining and metal mining are necessarily separated from each other by a legislative barrier, a volume devoted entirely to coal mining will, no doubt, be welcome and will prove a great advantage Whether the artificial setting up of such a barrier in the United States, which this volume indicates, will be equally beneficial to American mining engineers may, for the reasons already stated, be open to doubt

Quantum Mechanics

(1) *An Outline of Wave Mechanics* By N F Mott Pp vi + 156 (Cambridge At the University Press, 1930) 8s 6d net

(2) *The Physical Principles of the Quantum Theory* By Prof Werner Heisenberg Translated into English by Carl Eckart and Frank C Hoyt (The University of Chicago Science Series) Pp xii + 186 (Chicago University of Chicago Press, London Cambridge University Press, 1930) 8s 6d net

(3) *Quantum Chemistry a Short Introduction in Four Non Mathematical Lectures* By Prof Arthur Haas Translated by L W Codd Pp ix + 77 (London Constable and Co, Ltd, 1930) 6s net

THE new theories of physics grouped under the title of 'quantum mechanics' are at present passing through a further stage in their development, in which the expositor is following close on the heels of the original investigator It is all to the good to have these less technical and less involved accounts of the theories

(1) Mr Mott, who is lecturer in theoretical physics in the University of Manchester, has written a book which will be of great value to a student who has completed an honours course in physics and wishes to understand the principles of wave mechanics Employing mathematical methods which should be familiar to such students, the author seeks to expound the general principles of the new quantum theory Extensive use is made of analogies from different branches of physics, and the result is a book which may be recommended to the advanced student of experimental physics and to the research worker It seems strange that the name of de Broglie is not mentioned on the first page along with the names of Heisenberg, Schrödinger, and Dirac, but the author makes amends on page 8 by calling the waves which represent certain of the properties of electrons de Broglie waves The purely symbolic character of these waves is insisted on from the outset, the fundamental assumption of wave mechanics being that our knowledge of the position and velocity of any particle can be represented by a wave "All that can be known about the electron in a hydrogen atom is summed up by the behaviour of a wave"

(2) As Prof A H Compton remarks in a foreword to this English edition of Heisenberg's work "The 'uncertainty principle' has become a household phrase throughout our universities, and it is especially fortunate to have this opportunity of learning its significance from one who is responsible for its formulation" In all experimental methods of making measurements of small scale phenomena there are limitations imposed by the interaction between the process of measurement and the measuring instrument, and it is the formulation of these limitations which constitutes the principle of indeterminacy The book is by no means an easy one to read, but there is no doubt that it will take an important place as an authoritative statement of Heisenberg's views on this aspect of the quantum theory

(3) In this book Prof Haas gives a short account of modern quantum theory in the form of four lectures for chemists In the first lecture he deals with the arithmetic of the periodic classification and describes the four quantum numbers required for the interpretation of line spectra The second lecture is concerned with the quantum theory of valency and chemical forces After an account

F 1

of London's theory of chemical combination, the difference between heteropolar and homopolar compounds is explained A digression on the subject of wave mechanics is followed by the hypothesis of Heitler and London that homopolar compounds of elements are due to the coupling by means of resonance of two similar atoms The third lecture is concerned with electron grouping and the periodic system, and is based on Pauli's principle The last lecture is of special interest, for in it the author discusses quantum problems of molecular and nuclear structure We find that the new mechanics gives an interpretation of radioactive disintegration as a chance phenomenon without any special hypothesis This gives us a beginning of a quantum theory of the nucleus This all too brief volume provides a convenient summary of recent theoretical work

Inorganic Chemistry

A Text Book of Inorganic Chemistry for University Students By Prof J R Partington Third edition Pp viii + 1083 (London Macmillan and Co, Ltd, 1930) 15s

THE third edition of this excellent text book will be as welcome as were its predecessors Compared with the first issue, which appeared in 1921, the biggest change made is the substitution of the original last chapter which dealt with the radio elements and atomic structure, by one of about three times its length, which is inserted earlier in the work, immediately after the elementary treatment of the Periodic Law Commencing with cathode and positive rays this new chapter (xxv — The Structure of the Atom) introduces the conception of isotopes, proceeds to discuss in turn X ray crystal analysis, atomic numbers, and radio active phenomena, touches on the Rutherford Bohr conception of the atom and the artificial disintegration of elements, deals with the octet theory of G N Lewis, different types of linkage, and quantum numbers, and concludes by a discussion of atomic structure, the periodic table, and valency, reference being made, *inter alia*, to the work of Grimm and of Fajans, and to wave mechanics

The book as a whole remains essentially as before, and displays all those qualities of clear, concise, restrained and yet fresh treatment which have justly led to its wide popularity in recent years The historical notes in the earlier chapters are particularly attractive, and the sponsorship of the author is a guarantee of their accuracy

The detail has been brought up-to date—thus, the oxides of bromine and of fluorine, chlorine fluoride, and chlorine hexoxide are mentioned Brief reference is also made to such matters as the connexion between energy and mass, cosmic rays, ortho and para hydrogen atomic hydrogen, active nitrogen, the adsorption theory of Langmuir, the shapes of molecules, the Debye-Hückel theory of strong electrolytes, and the quantum theory of specific heats

Opinions will differ as to the desirability of the mention of, at all events, some of these topics, as of those in Chapter xxv, in what is designedly a relatively elementary book, even when admitting that a judicious use has been made of small type (which, incidentally, has helped to keep the size of the volume sensibly as in previous editions) With intelligent students *and* teachers, there should be no trouble in other cases, there is an obvious danger that, when used as "a reference book for higher forms in schools", a type of instruction in chemistry may be fostered which university teachers are practically unanimous in deploring There are few other points open to any criticism The statement, however, on p 198, that the photochemical union of hydrogen and chlorine "when once started, goes on spontaneously", is misleading if taken away from its immediately preceding context

Our Bookshelf

Forestry a Study of its Origin, Application and Significance in the United States By Prof Arthur B Recknagel and Prof Samuel N Spring Pp xii + 255 + xxxvii (New York and London Alfred A Knopf, 1929) 10s 6d

IN this book, the two authors, well known members of the staff of Cornell University, set out to discuss the present day economic problems of the forestry question in the United States They state that they were encouraged to undertake the work by "the tremendous interest which many people have taken in the country's forestry problem, and by the need of orienting the public, particularly the younger generation in schools and colleges, in the important economic aspects of this problem" These words might equally well have been written for Great Britain, with the exception that instead of having the forestry problem restricted to one country, ours is scattered all over the world, the most important work being outside the small island of Great Britain

The book under review is in no sense intended as a compendium of forestry information nor is it a manual of methods Its sub title explains the aims of the authors Some of the economic problems of present day forestry are common to many parts of Europe, the biggest one being the question of the possible shortage of coniferous softwood supplies The position of the United States, that great

exploiter of coniferous forests during the past half century, is well known in this respect Inter-State imports have been proceeding for some time past, and the United States will for some decades to come import forest produce on an increasing scale From the British point of view, perhaps the first two chapters of this book will prove of greatest interest The first, "How Forestry came into being", gives us an excellent summary of the various stages the forests and forestry in the United States have passed through since their utilisation by the white man first commenced In the second chapter we are shown how the early movement towards forest protection and conservation ran parallel with the immense economic development of the forest industries, the merging of these two great movements being discussed in subsequent chapters The second half of the book deals with the introduction of principles and methods of forestry with the advent of the trained forester, with education and research, and the real status of forestry in the United States administration The authors may be congratulated on the way they have handled their material and presented it to the public

Beiträge zu einer einheitlichen Auffassung gewisser Chromosomenfragen mit besonderer Berücksichtigung der Chromosomenverhältnisse in der Spermatogenese von Alydus calcaratus *L* (*Hemiptera*) Von Enzio Reuter (*Acta Zoologica Fennica*, 9) Pp viii + 487 + 8 Tafeln (Helsingforsiae Societas pro Fauna et Flora Fennica, 1930)

THIS work is a careful cytological study of spermatogenesis in a Hemipteran insect, but it is much more, for it includes a discussion of literature in all the related fields of plant and animal cytology After some sixty pages giving a critical account of spermatogenesis in this insect, the remainder of the volume is devoted to a discussion of such questions as the structure of chromosomes, hypotheses of chromosome phylogeny, chromosome persistence and composition, the 'resting' period between mitoses, chromosome splitting, the method and meaning of chromosome conjugation, the nature of genes, and other questions The views and observations of others are freely cited, making the work a very useful one in comparative cytology

The questions considered are much too numerous to discuss here, but it may be mentioned that in the spermatogonial nuclei of *Alydus* the chromosomes split in the prophase The somatic number is 13, consisting of five pairs of ordinary autosomes of different sizes, one pair of micro chromosomes, and the *X*, which, as usual, becomes compact at an early stage The oogonial divisions show two *X*-chromosomes

Some of the drawings of chromosomes are made from the living cell There is no continuous spireme or bouquet stage, but the long chromosomes in meiosis pair laterally, beginning at one end, to form five gemini Remaining attached at one end, they afterwards diverge until they are end-to-end and then split lengthwise Before reaching their definite shape in diakinesis, they pass through characteristic extended (chromomere) and diffuse stages But it is strongly emphasised that from the last spermatogonial telophase to diakinesis all the chromosomes maintain strict genetic continuity as separate and distinct individuals The *X* chromosome is seen *in living cells* to be composed of four segments

All biologists wishing a critical summary of the present position on these cytological questions will find this work useful The bibliography alone occupies more than a hundred pages R R G

Einführung in die Bodenkunde der Seen Von Einar Naumann (*Die Binnengewässer Einzeldarstellungen aus der Limnologie und ihren Nachbargebieten*, unter Mitwirkung von Einar Naumann und herausgegeben von August Thienemann, Band 9) Pp ix + 126 + 7 Tafeln (Stuttgart E Schweizerbart'sche Verlagsbuchhandlung (Erwin Nägele) G m b H, 1930) 16 gold marks

THE part of 'Die Binnengewässer' before us deals exclusively with lake bottoms It is a large and interesting subject and very thoroughly handled from all aspects The study of fresh waters as undertaken at the present day is a comparatively recent branch of science, and there has arisen, with its growth, a number of new terms, mostly introduced by the Swedish school at the Limnological Laboratory Aneboda, of which Dr Naumann is director This laboratory is a model for all such fresh water research Most of these terms have come to stay, although many of them have no English equivalent Good definitions are given throughout the work The chapters deal with the development and origin of the various bottoms, their layers and zoning, principles and methods of sampling, with descriptions of apparatus, the botany and zoology of the layers, including bacteria and the organic and inorganic deposits All these are carefully classified and described *Bodenkunde* is the study of the origin, qualities, and changes of the bottoms In it, geology, zoology, and botany are all involved, besides physics and chemistry It is an extremely important part of the larger and wider study of fresh waters in general This volume is indispensable to all those engaged in such researches, and is one of the most interesting of the series It is illustrated by photographs, maps and text figures which are good and well selected

A Century of Wood Preserving Edited by Sir Harold Boulton Pp x + 150 + 3 plates (London Philip Allan and Co, Ltd, 1930) 8*s* 6*d* net

AT the present time, when a renewed interest in the scientific study of wood preservation is being shown in Great Britain, it is well to recall that this country was a pioneer in this work, and the method of forcing antiseptics into timber by means of pressure in a cylinder was patented by Bethell so early as 1838 "A Century of Wood Preserving", edited by Sir Harold Boulton, contains the substance

of a paper read in 1884, before the Institution of Civil Engineers, by his father, Mr S B Boulton, who gave a complete and valuable survey of the progress made up to that date An account of the discussion which followed is reprinted and makes interesting reading, reminding us that the theory of the action of preservatives which was attributed to the coagulation of albumen was not yet dead at that date

Recent developments are briefly summarised by Mr Hubert Fergusson, and in the numerous appendices are reprinted some of the original patents and early papers referring to the action of preservatives The history of wood preservation has been one of trial and error, but advance must always be slow in work where results from practical experiments do not become available for many years Accurate scientific investigations are now beginning to take the place of empirical conclusions which have long been accepted as facts The experience of the past is apt to be forgotten, and the volume under review is of value in recalling to us the work achieved and the considerable knowledge of the subject that had been gained half a century ago The name of Boulton has long been associated with the progress of wood preservation, and it augurs well for the success of the newly formed British Wood Preserving Association that its first president should bear the name of the editor of this book

The British Journal Photographic Almanac and Photographers' Daily Companion, with which is incorporated The Year Book of Photography and Amateurs' Guide and The Photographic Annual, 1931 Edited by George E Brown Pp 748 + 64 plates (London Henry Greenwood and Co, Ltd, 1931) Paper, 2s net, cloth, 3s net

BESIDES the usual epitome of progress, formulæ, tables, and miscellaneous information, this volume includes concise essays on the makers of photography, modern enlarging, and colour photography, with a note on bromoil The "Makers of Photography" is by the editor, and is a history of the development of photography from the earliest times up to approximately 1890, though, as might be expected, the last twenty or so years of the period is very sketchily done The value of this article lies in the history of the earlier periods, practically the first half of last century, as certain items which have only recently come to light are duly incorporated for, we believe, the first time The other articles also are excellent summaries of the subjects with which they deal

The advertisements, which are a very valuable section of the work, show what great advances have been made in the development of the apparatus for cinematography Lenses are now provided for it up to the extraordinary aperture of *f*/1, and cameras costing from a few pounds up to £250 or more

The "Gravure Pictures" are not of scientific value, but a considerable number appear to us to have been made from very much under exposed negatives However, that appears to be the fashion at present

Photo electric Cells and their Applications a Discussion at a Joint Meeting of the Physical and Optical Societies, June 4 and 5, 1930 Editor Dr John S Anderson Pp 236 (London The Physical and Optical Societies, 1930) 12s 6d

A descriptive account of the discussion on photoelectric cells arranged by the Physical and Optical Societies appeared in the issue of NATURE for June 21, 1930 This volume contains the original papers contributed by various authors, together with the general discussion which took place at the meetings at the Imperial College of Science and Technology The subject affords an excellent illustration of the importance of research in pure science, as few of the original workers in the subject of photo electricity could have anticipated the various technical applications which have arisen in connexion with their discoveries Not only in photometry, but also in connexion with such diverse problems as talking films and photo therapy, photo electric cells have been employed, and the successful solution of the problem of television is probably to be found through their use The relative merits of different types of cell provided material for much discussion, but as the sensitivity of a cell is largely a matter of definition, no general agreement was reached It is probable that the rivalry between the alkali metal cell and the selenium cell will continue, as each type seems to possess advantages for special purposes Although theoretical questions were not the main subject of the discussion, some interesting papers were contributed dealing with the theory of photo electric action, notably Dr N R Campbell's paper on selective photoelectric emission

The American Annual of Photography, 1931 Vol 45 Edited by Frank R Fraprie Pp 292 + Ad 64 (Boston, Mass The American Photographic Publishing Co, London Sands, Hunter and Co, Ltd, 1930) Paper, 7s 6d, cloth, 10s 6d

OF the twenty nine literary communications to this 'Annual', we note specially Dr Wightman's discourse on "Light and Matter", in which he traces the history of the subject and describes the theories at present held, and Dr Maximilian Toch's "Scientific Photography of Oil Paintings" Dr Toch demonstrates by examples that experts cannot judge of the condition of a painting from a photograph of it, "because it depends entirely upon how the photograph was taken as to whether the picture appears good or not" He gives some of the results of his prolonged experience Mr Neblette, as in previous years, contributes a review of the progress in photography for the past year The very large number of formulæ given are for the most part set forth in convenient tables, which save space and facilitate reference and comparison As the illustrations claim to be pictorial, we hesitate to remark upon them, but the under-exposure in many cases, and in some a slaty fog that covers the whole and is particularly conspicuous by artificial light, do not commend themselves to us as good photography.

Letters to the Editor

[*The Editor does not hold himself responsible for opinions expressed by his correspondents Neither can he undertake to return, nor to correspond with the writers of, rejected manuscripts intended for this or any other part of* NATURE *No notice is taken of anonymous communications*]

A Method of Measuring Upper Atmospheric Ionisation

THE experimental investigation of the electrical structure of the upper atmosphere by means of wireless waves as the exploring agency has shown that there exist two main ionised regions from which such waves may be reflected The lower of these regions is the Kennelly Heaviside layer, which reflects long waves in long distance transmission The upper region is found to be much richer in ionisation than the lower so that if we project vertically upwards waves of gradually increasing frequency (and therefore gradually shorter wave length) we find that, at a certain critical frequency, the lower region is just penetrated and reflection takes place from the upper region

In experiments carried out during the last twelve months it has been found that the value of this critical frequency is surprisingly definite and therefore can be taken as a measure of the ionisation content of the lower region

The relation between the critical frequency f and the value N of the maximum number of electrons per cubic centimetre can be derived as follows Waves sent into a medium of gradually increasing ionisation are reflected at a region where the refractive index μ tends to zero For a magneto optical medium such as the upper atmosphere I have shown (*Proc International Union of Radio Telegraphy*, vol 1, part 1 1928) that such conditions are reached for any direction relative to the earth's magnetic field H_0 when

$$\text{either} \qquad \mu^2 = 1 - \frac{\dfrac{Ne^2}{\pi m}}{f^2 + \dfrac{1}{3}\dfrac{Ne^2}{\pi m}} = 0,$$

$$\text{or} \qquad \mu^2 = 1 - \frac{\dfrac{Ne^2}{\pi m}}{f^2 \pm ff_H + \dfrac{1}{3}\dfrac{Ne^2}{\pi m}} = 0,$$

according to the polarisation of the waves Here e and m are the electronic charge and mass, and f_H is equal to $\dfrac{H_0 e}{2\pi mc}$ The results of an experimental study of the polarisation of downcoming waves (*Proc Roy Soc*, A, vol 117, p 576, 1928) lead us to adopt the second equation with the upper sign for ff_H The relation between the maximum electronic content N and the critical frequency is therefore

$$N = \frac{3\pi m}{2e^2}(f^2 + ff_H)$$

In experiments carried out between the emitting station at the National Physical Laboratory, Teddington, and receiving stations at King's College, London, and the Radio Research Station, Datchet, a technique has been developed which permits one determination of the critical frequency in a period of an hour, and we have reason to believe that, with still more experience on the part of the observing personnel, this period can be reduced to half an hour

A recent twenty four hour run using this method has shown that for a mid winter day over southern England the value of N reaches $2\ 0 \times 10^5$ electrons per c c at noon, after which the value falls steadily and remains at the low value of 3×10^4 during the greater part of the night About half an hour before sunrise a very sharp increase is noted, after which the ionisation increases more gradually until the maximum midday value is again reached The noon value of ionisation is thus found to be more than six times the midnight value

The diurnal variation curves bear a pronounced resemblance to theoretical curves deduced by Prof S Chapman (*Proc Phys Soc*, vol 43, part 1, p 26, Jan 1931) for a case of atmospheric ionisation by monochromatic radiation

The experiments have been carried out as part of the programme of the Radio Research Board of the Department of Scientific and Industrial Research

The Meaning of Existence

OTHERS perhaps besides myself may have regretted that the recent correspondence between Sir Oliver Lodge and Sir James Jeans should have closed just at the point at which questions were raised by it that go far beyond the actual issue between these distinguished physicists, and yet may have an important bearing upon it Asked whether ether *exists*, Sir James sums up his attitude to the question in the words, "nothing in science seems to exist any more in the good old fashioned sense --that is, without qualifications, and modern physics always answers the question 'To be or not to be?' by some hesitating compromise, ambiguity, or evasion" (NATURE, Dec 6)

To those approaching the question from the side of metaphysics rather than of physics this conclusion is likely to seem one of the most interesting outcomes of present day discussions as to the status of physical reality Physics seems here to have arrived by its own path at the position made familiar to philosophers in the last generation in America by William James in the brilliant section of his " Principles of Psychology " which deals with " The Many Worlds ", in England by F H Bradley in the chapter in 'Essays on Truth and Reality " entitled " On my Real World " These writers approach the subject from different sides James characteristically being concerned with 'belief', Bradley with 'reality', but one point which they have in common is precisely that of Sir James Jeans, namely, that before there can be any talk of existence you must define the world within which it is affirmed—what the logicians call 'the universe of discourse' within which your proposition falls Is it, for example, the universe of ordinary sense perception, defined by Bradley as that which is "continuous with the felt, waking body", or is it one of those 'sub universes', as James calls them, though 'super universes', in some cases would be a better word—the world, for instance, of history in which Julius Cæsar or of poetry in which Hamlet lives and moves and has his being ?

It is, however, not merely a question of different worlds Within the same world [illegible] mbiguity breaks out In the world "conti[illegible] th the felt, waking body"—the world, for ex[illegible] of the pen I hold in my hand and the action t[illegible] moves it—there is the difference between the appearance in time and space, the 'here' and the 'now' and the enduring system of atomic events in the pen, of habits and disposit[illegible]

in the movement If existence means what is all here and now, it is difficult to see in what sense these latter, the essence of which is just not to be all here and now, can be said to exist If, on the other hand, it means that which appears or expresses itself in what is here and now, it is difficult to see how we can assign more to the here and now than the shadowy form of the really existent Finally (and this brings us back to what Sir James Jeans has probably in view) we have the difference between the particular and the universal, in the ordinary sense the difference (to confine ourselves to the physical) between the pen and the law of its mass, where the same difficulty again meets us—the difficulty that has engaged philosophers from the time of Plato to the present day, and has led some of them to deny existence to that which appears to sense except as 'the moving image' or perceptible embodiment of an intelligible essence

Whether these distinctions throw any light on the controversy as to the existence of ether it is not for a mere metaphysician to say But it suggests at any rate that while those who maintain its existence may be making a mistake in thinking of it in terms of something that is continuous with the world of the felt, waking body, or as something that can be said to fill space they yet may be right in insisting that the word stands for an element in that world which the resolution of it into mathematical symbols or 'pointer readings' fails to make intelligible What is emerging more and more from the treatment of the world of sense perception from a philosophical point of view, is that, do what we can by our constructions, algebraic or other, to express it in conceptual terms there remains, as a surd, an element of inexpugnable givenness which must be taken not only as 'existent' but also as the source of the real existence of every thing else belonging to that world

Other questions of interest both to the physicist and the metaphysician are suggested by Sir James Jeans's reply chief among them the sense in which he would admit the existence of what it has come to be fashionable to call 'values' of which truth beauty, and goodness are stock examples Do these, as some things he has elsewhere said seem to imply, occupy a world apart from existing things? Or are they, as Prof Whitehead insists, a side of them apart from which no intelligible account can be given of them? But this is another story carrying us far beyond the particular point to which the discussion refers

Meteorological Conditions during the Air Raid on London, Oct 19-20, 1917

IN NATURE of Nov 29 1930, p 847, Col E Gold, discussing upper air conditions, states that the note under 'Historic Natural Events", in NATURE of Oct 18 1930, p 633, gives a misleading impression of the cause of the high winds at an altitude of 10,000 20,000 feet on Oct 19-20, 1917 A true explanation of the air structure which led to the loss of four German airships is of some importance though not bearing directly on the loss of the *R101* In "Aids to Forecasting" (M O Geophysical Memoirs No 16) types IV and VI are listed for Oct 19 and 20, 1917 The former shows '*lows*' north west and north east of the British Isles, and the latter an advancing '*low*' with characteristic pressure gradients For Oct 21 the type indicates a deep V-*low*

Col Gold is of opinion that although there was no pressure gradient at sea level, there was a steep west to east gradient at great heights, due to a steep horizontal gradient of temperature also from west to east Such a wind was a thermal wind only, and surface pressure "had nothing to do with the case" Trustworthy records are meagre, and the argument for the assumed steep horizontal temperature gradient and thermal wind rests mainly upon a record at Ipswich on the forenoon of Oct 20, which shows an isothermal condition at 4400 metres The case is discussed by Sir Napier Shaw in his "Manual of Meteorology", part iv p 112, and it may be that the record rightly tells of the remnant of a tongue of relatively warm air passing east The important point, however, is that at the ground there was little or no wind, and with clear skies radiation had full play There was no convection, and so a characteristic ground radiation fog formed In other words, there was a temperature inversion in the lowest level, whatever happened above London had no need of anti aircraft guns that night Its citizens slept in quiet, unaware that four of a fleet of eleven airships were overhead laden with bombs Nature provided a defence which cost nothing, was noiseless, and thoroughly effective

The whole story of that great air raid will probably never be made public Owing to failure of radio and loss of touch with Nauen, the ships went astray From midnight to 7 A M of Oct 20 they moved south east instead of east, unaware apparently of drift, unless the course was in error If there was a northerly wind at 4400 metres it had little or no strength at lower levels, and the airships probably flew low for several hours, seeking to penetrate the fog and locate themselves What saved London was not the northerly wind at high levels but radiation fog at the surface For forecasting purposes in connexion with aviation, the likelihood of fog at low levels would seem to be a matter of prime importance

ALEXANDER MCADIE

Blue Hill Observatory,
Readville, Mass, U S A

I THINK Prof McAdie's view of the vital importance of fog in aviation will command general assent, and I am not acquainted with anything contrary to his suggestion that fog prevented the German airships finding their objective on the occasion in question This, however does not explain why the airships drifted so far south and failed to return to their bases The strong northerly winds at great heights, of which the ordinary weather maps of surface conditions gave no definite indication do furnish a reasonable explanation of this fact

I do not think the existence of these northerly winds admits of doubt they were actually observed by pilot balloon in north east France on the night of Oct 19, 1917, at a height of 14,000 feet Nor do I think there is any doubt about the existence of the steep horizontal gradient of temperature with the distribution of surface pressure which existed at that time, there could not have been strong northerly winds at great heights without a steep horizontal gradient of temperature The question on which there may be difference of opinion is, whether the northerly winds were the cause or the effect of the horizontal gradient of temperature (if one can speak of cause and effect in connexion with phenomena which must co exist and which must develop together)

Separation of Bitumen from Bituminous Sands

THE separation of the bitumen from the Alberta bituminous sands by washing with hot water has been under study by the Research Council of Alberta for a number of years. It has been found that generally good separation can be effected by first thoroughly mixing the bituminous sand with about one fifth of its weight of a solution of commercial silicate of soda of 2 per cent or less concentration, heating the mixture to a temperature of about 85° C., and then introducing the bituminous sand thus treated into a body of hot water also at a temperature of about 85° C. The bitumen collects on the surface of the water as a froth. Runs through our laboratory separation plant using recently mined bituminous sand of from 10 to 17 per cent bitumen content yield separated bitumen containing 5 per cent or less of mineral matter. However, in spite of careful control of ordinary factors, such as temperature, quantity and concentration of reagents, time of treatment, rate of feed, etc., it has not seemed possible to duplicate results closely. Two batches from the same supply of bituminous sand might give separated bitumens containing 1 and 4 per cent of mineral matter, although care had been taken to separate them under similar conditions.

Last summer we operated a 25 ton per day separation plant at the bituminous sand deposits in Northern Alberta. Bituminous sand from some parts of the quarry acted very badly in the plant and gave poor results. When such material was being run it was noted that the plant water became distinctly acid. Samples of bituminous sand were collected from various points in the quarry. These were stirred up in from two to three times their volume of water and the acidity of the water noted. The pH values varied from 2.5 to 6.4.

At a location some fifty miles distant from our plant a private party was separating bituminous sand by hot water. The separation plant was very crude and no treating reagents at all were being used. Yet separation results were apparently good. Water in which bituminous sand from this location was stirred gave a pH value of 6.4.

Supplies of sand from our quarry that had given varying degrees of trouble were brought to our laboratory at Edmonton. It has been found that if, in the preliminary treatment of the bituminous sand, alkali is added until the pH value of water in which a test sample of the batch has been stirred becomes 6.4 or higher, the treated material then gives excellent separated bitumen on washing in hot water. A series of runs shows steady improvement in the cleanliness of the separated bitumen as the pH value of 6.4 is approached, but little change as this value is passed. Sodium hydroxide and silicate of soda, both singly and in combination, have been used so far.

A preliminary washing of a refractory bituminous sand in cold water has the result of greatly diminishing the quantity of alkali which must be added to bring the pH value to 6.4. It also has the advantage of removing clay from the bituminous sand, if clay is present. Clay apparently has a bad effect on separation, as well as causing trouble by fouling the plant water.

The acidity in the bituminous sand is probably due largely to ferrous and ferric salts carried into the bituminous beds by ground water passing through the clayey overburden. Salt incrustations appeared on some parts of the face of our quarry. Analysis showed that this salt accumulation was a mixture of ferrous, ferric, aluminium, calcium, magnesium, and sodium sulphates.

A careful study of the effect on separation of adjusting the acidity of the bituminous sand in the preliminary treatment and of related factors is being made. The detailed results of the study will be published in due course.

Nutritive Value of Benniseed

THE question of the nutritive value of benniseed (*Sesamum indicum*) was recently raised and analyses were carried out in this laboratory. This seed is grown along the Benue River and its tributaries by the various clans of the Munshi or Tiv people. A small amount of it is eaten and a little oil is extracted, but the bulk of the crop is exported, I gather, to Europe for the manufacture of 'salad oil' and the very fine grade machine oil called 'Sesame'. What happens to the 'cake' I do not know.

Analyses gave the following relevant percentages: Oil 52.6, protein 23.4, total ash 4.0, CaO 1.2, P_2O_5 1.39, from seed grown in the Yandev Area of the Benue Province. The Government Analyst, Mr. A. Hobson, has confirmed the calcium oxide percentage, but his phosphoric anhydride figure is 1.13 per cent.

All analyses of Nigerian soils so far carried out not by this laboratory show exceedingly poor figures for calcium and phosphorus and so the percentages of these minerals in benniseed would be sufficiently astonishing on these grounds alone; but I can find no recorded analyses showing a higher calcium content for any food: cheese is 0.9, for example, and only New Zealand spinach and the leaves of the sweet potato seem to approximate to this exceedingly high figure; nor can I find any ash analysis of benniseed itself.

As previous work has shown[1] the natives of Northern Nigeria suffer from gross deficiencies of calcium and protein in their dietary, and so the importance of benniseed cake is at once obvious. Indeed, measurements of the boys in the Dutch Reformed Church's Mission School at Mkar show clearly, within the limitations imposed by the numbers, that the benniseed eating Munshi boy is shorter but heavier than the Hausa schoolboy.

There might be an even more important general point. It has become the fashion to discount soil analyses in some nutritional quarters, and to use instead the analyses of the crops that grow on the particular soil. Benniseed grown in the arid north of Katsina Emirate and from French territory contains 1.18 per cent of calcium oxide, and, therefore, it would appear that this plant exercises a strong selective absorptive power for calcium. There is no reason to believe that other plants will not show the same capacity. It might prove of value to soils poor in calcium and phosphorus to plant benniseed to concentrate these minerals, and then to plough in the flowering plant, or the dried plant after the crop has been reaped. I have just been informed that the Munshi women burn the seed bearing heads, after removing the seeds, and use the ash in their soups. This is a strong hint to analyse the leaves and the stem.

Green manure is firmly established as a way to increase available nitrogen and to prepare humus in arid regions, and so it might be worth while to attempt concentrating minerals in deficient soils, such as Northern Nigeria, by the same method. Such work must have been attempted somewhere, but I am unable to find any reference to it in the limited

literature at my disposal This letter may serve, I hope, to initiate such experiments, or to bring to our notice in Nigeria work already done

Determination of the Velocities of Projectiles by the Method of Light Interception

Messrs Payman and Woodhead appear to have misunderstood the method described in our letter in Nature of Dec 27, p 994 We made no claim to originality of application of the principle of light interception Our method does not depend on shadow or ordinary photography, which has been used in ballistics since the time when Boys took his first shadow photographs in 1893, and differs from that used in other optical chronographs (see, for example, Cranz, "Experimentelle Ballistik", **3**, chap ii, 1927), of which Kampé de Fériet's is one

Fériet's method consists in taking a continuous photograph of the projectile itself, by ordinary day light photography, on a plate moving at right angles to the direction of flight The records show a band at an angle to the direction of motion of the plate The velocity determination involves the measurement of this angle There are no discreet interceptions as in our records

In our method the motion of the film of the camera (which is a simple drum camera with a cylindrical lens at the shutter, not a 'photographic' camera in the ordinary sense) is parallel to the axis of flight The projectile eclipses one or more beams of light which are brought to a fine focus (less than one millimetre) on the line of flight, and it is these eclipses or interceptions of the beams by the body of the projectile in flight which are recorded, not the reduced shadow images of the projectile In Fériet's method there is no 'range' in the technical sense, in our method the 'range' is the accurately measured distance between the two foci of the interception beams on the line of flight Fériet's camera gives the ratio—velocity of projectile to velocity of plate—whereas our camera simply gives a time interval between the eclipses by the body of the projectile of two fine beams of light placed a known distance apart The difference is obvious when it is realised that a velocity determination can be made from Fériet's photographs alone, without other data, whereas from our photographs it is not possible to determine a velocity unless the 'range' is known

Since the publication of our original letter in Nature of Dec 27, 1930, we have learned through the courtesy of the Director of Ballistics Research, Woolwich, that a method on the same principle as our own was developed by Thompson, Hickman and Riffolt and published in the *Proceedings* of the U S National Academy of Sciences (*Proc*, **6**, 169, April 1920) These workers utilised a single narrow beam of light, whereas we utilise two finely focused beams the illuminating and recording apparatus is different but the principle is the same

Embryology and Evolution.

In the issue of Nature for Dec. 13, Mr. G. L. Purser gives us an analogy of the modern manufacture of motor cars as a contribution to the solution of the problem of embryonic evolution which is novel and interesting, but far from satisfactory

The comparison of the function of the hypothetical gene to that of an intelligent workman is but adding to the mystery Often the workman in the modern factory functions merely as the trigger-release of processes altogether beyond his ken, and subservient to the will and preconceptions of the motor car designer The more excellent the machine, the less dependent it is upon the control of the workman intermediary, but however excellent the machine, the sole origin of that excellence lies obscurely hidden in the phenomenon we term intelligence Devoid of motive power, the most excellent of all machines stands immobile It cannot move productively unless, again by some intelligence, a motive force is accurately applied, and the moment this force ceases to reach it, the machine stops

Most of us before we reach the age of ten have learnt that anything which 'goes' is driven by a force external, yet although we live to be a hundred, what a host of us regard with sublime abhorrence the suggestion that the same thing is likely to be true in regard to living cells! We willingly accept the validity of 'kinetic', 'electrical', gravitational', or other forces, but we dogmatically affirm that a 'vital' force is but a bogy from the limbo of fantastic superstition, and so we evoke the genie, perhaps the gene, and by its spell try to account for all we see—with as much success as if we claimed that the revolving flywheel of our motor engine were the real source of its motive power

Personally, I feel that incredulity of a 'vital' force is scarcely any longer compatible with true scientific observation Anyone who has studied mitotic division of the cell and is conversant with electro-physical phenomena feels instinctively that he is observing the action of a force strikingly similar to that of the magnetic field Irradiation with ultra violet light is found to augment the process of ovulation in the domestic fowl, while the reproduction of fur-bearing animals in northern lands is strangely correlated with magnetic solar radiation

Entelechy, like the word phlogiston, may be the signpost on the way to a new enlightenment, which will, I predict, ere long result in the acceptance of the view that the living cell is, after all, merely a machine primarily operated by some external force Even so, let us remember that vitalism and spiritualism are not synonymous

Use of Tungsten Arc Lamps for Photomicrography.

The uniform intrinsic brilliancy and compactness of the tungsten arc lamp have led to its extensive application as an illuminant for photomicrography It does not appear to be generally recognised, however, that the light which leaves the metal surface at angles approaching a tangent is so strongly plane polarised that it is difficult to obtain uniform illumination when crystals are being photomicrographed by plane polarised light

The polarised light emitted at an acute angle to the incandescent metal surface has its vibration direction parallel to that surface This effect may be shown by projecting an image of the incandescent tungsten sphere on to a white screen by means of a 2-inch objective, and then interposing a Nicol prism

in the beam of light, when the edges of the image parallel to the long diagonal of the Nicol are darker and those parallel to the short diagonal are brighter than the centre of the field By placing a '1st order red' selenite between the light source and the Nicol prism, the edges of the image appear red or greenish-blue according to their orientation with respect to the prism

The degree of lack of uniformity of illumination which can result when 'contrasty' photographic materials are used in photomicrography by polarised light, is shown in Fig 1, *a*, *b*, *c*, which are photographs

a *b* *c*

FIG 1

of the tungsten sphere of a Pointolite lamp. Fig 1*a* was the ordinary appearance in the absence of a Nicol prism, whereas Figs 1*b* and 1*c* show the appearance when a polarising prism was interposed with its plane of vibration horizontal and vertical respectively

This effect, which is not given by either a carbon arc lamp or the sun, could give rise to appreciable errors if a tungsten arc lamp were used for spectro photometry without the interposition of ground glass to form a secondary source

Wealdstone, Jan 14

A Relation between the Radial Velocities of Spiral Nebulæ and the Velocity of Dissolution of Matter

I SHOULD like to make the following comments upon Dr McCrea's remarks in NATURE of Dec 6, 1930, upon my letter in NATURE of Nov 8, my comments also apply to a certain extent to Dr Wilhelm Anderson's letter in the issue of Dec 6

(1) As I have shown recently (*Anzeiger der Akad d Wiss Wien*, 1930, No 16), equation (1) can also be deduced without general relativity theory from the postulate that the total energy of the universe cannot be negative, or that the negative gravitational energy of the universe corresponds in magnitude with its proper energy By mass in equation (1) Eddington's proper mass is to be understood

(2) It is true that a negative velocity results, as Dr McCrea insists, I have, however, indicated this myself in my letter, where I showed that v agrees well with the radial velocity of the spiral nebulæ only in *magnitude*, that is, without reference to sign

(3) If, again, my equation (2) is to be interpreted from the point of view of Lemaître's theory, with introduction of a temporal variation of λ, then it must not be overlooked, on the other hand, that Lemaître's theory requires further assumptions to make it complete Such would, perhaps, be necessary to bring the assumption that the velocity becomes greater by $c/2000$ for every million light years' distance in agreement with the other assumption that the initial radius of the universe, calculated to be 1200 million light years, is doubled every 1400 million years, that is, within a time shorter even than the age of many minerals—not to speak of astronomical estimates of the age of the sun.

ARTHUR HAAS.

University of Vienna, Jan 3

Photographs of John Dalton.

I SHALL be glad if any readers of NATURE can assist me in tracing the present whereabouts (if still in existence) of three original photographs of Dr John Dalton These were taken in Manchester, at one sitting, somewhere about the year 1842, by the Daguerre process, then recently introduced into Great Britain, and so far as I know were the only photographs of the great chemist ever made Their production has been wrongly attributed to John B Dancer, the fact being that it was through Dancer's good offices that Dalton was induced to sit at the local Daguerre studio

It is on record that one of the three copies passed to Dalton himself, another to Dancer, and a third to Mr John Dale, manufacturing chemist Dancer's passed at the time of the Jubilee exhibition in Manchester in 1887 to Mr (afterwards Sir James) Dewar, the eminent chemist, I have also seen it stated that another (possibly Dale's) was in the possession of the late Mr Thomas Kay, manufacturing chemist, of Stockport There is no trace of such a photograph in the collection of Dalton's apparatus at the house of the Literary and Philosophical Society where he did so much of his work, nor in the more personal relics preserved at Dalton Hall

Dancer's photograph was lent by him on various occasions to artists and engravers for copying, and became somewhat disfigured in consequence

Perhaps this letter may meet the eye of someone who has actually seen one of the originals or can assist me in tracing them

HENRY GARNETT

3 Lea Road, Heaton Moor,
Stockport, Jan 19

The Black-necked Grebe

IN the note upon this bird (NATURE, Jan 3, p 35) its generic name is given as *Podiceps*, perpetuating an error in orthography for which, I think, Yarrell was originally responsible and has been followed by some later writers on ornithology On the analogy of *biceps*, *calviceps*, etc, *Podiceps* can only be translated 'rump-headed', whereas the right name of the genus is *Podicipes* (Linn), meaning 'rump footed', referring to the peculiar position of the legs and feet in birds of the family Podicipedidæ

HERBERT MAXWELL

Monreith

WERE all taxonomists as familiar with the classical languages as is Sir Herbert Maxwell, mistakes such as he points out would be rarer, but although they appear in Latin guise, generic and specific names need not be evolved from anything but the author's sense of propriety The name is a label and need have no meaning in itself The consequence of that, and of the accepted rule of nomenclature that the first legitimate christening holds the field, is that *Podiceps*, used by Latham in 1789 to designate our grebes, is now the accepted generic name

THE WRITER OF THE NOTE

Dimorphism of Long Chain Carbon Compounds

FROM recent X ray measurements (Malkin, NATURE, Jan 24, p 126) it is claimed that the ethyl esters of fatty acids may have two forms of chain An account of an investigation of several binary systems of C_{16} and C_{18} compounds will shortly be published, in which it is shown that the ethyl esters are dimorphous, ethyl palmitate melting at 19 4° or 24 15°, and ethyl stearate at 30 9° or 33 4°

J C SMITH

The Dyson Perrins Laboratory,
Oxford, Jan. 29

The Significance of Peking Man.*

By Prof G ELLIOT SMITH, F R S

THE brain-case found by Mr W C Pei at Chou Kou Tien on Dec 2, 1929, is the most significant and illuminating relic of primitive man ever recovered Prof H Fairfield Osborn, writing in *Science* of Feb 22, 1929, raises the possibility that Piltdown man may be so old as the Pliocene He claims that the dark-coloured fragments of the skull of *Eoanthropus* are intermingled with similarly coloured fragments of proboscidian molars of unquestionably Upper Pliocene age, and that it is not certain that *Eoanthropus* belongs to the Lower Pleistocene In the case of *Sinanthropus*, there is no such uncertainty as to the contemporary fauna, for the human remains were left on the floor of a cave and a vast number of the animals which roamed the region of Chou Kou Tien in these remote times left their bones in the same cave As all these fossils belong to the same geological epoch, the Lower Pleistocene, there can be no doubt of the age of *Sinanthropus*

The discovery, at Chou Kou Tien, of fossil teeth of Lower Pleistocene age which were identified as human, had made it evident that at the close of Tertiary or the beginning of Quaternary time man, or a very closely related anthropoid, actually did exist in eastern Asia This knowledge is of fundamental importance to students of human palæontology For in the same geological epoch *Pithecanthropus* was living in Java, *Eoanthropus* was roaming the region around Piltdown in England, and at Mauer, very shortly afterwards, the man of Heidelberg, *Palæanthropus*, represented the human family in Germany

In November 1928 additional remains of human skulls—further teeth, portions of two lower jaws and fragments of brain-cases—were found The peculiar features of the chin region of these jaws differed from those of all other known human specimens excepting only the Piltdown jaw, to which they present a general resemblance, without being generically identical There is a similar ape-like obliquity in the slope of the symphysis and traces of the simian shelf in the lingual aspect of the jaw Not only do these peculiarities emphasise the peculiar features of *Sinanthropus*, but they also afford welcome confirmation to the views of those who regard the Piltdown jaw as human

The skull discovered by Mr W C Pei was successfully freed from travertine after a labour of four months by Dr Davidson Black, and then disarticulated and reconstructed It is important not merely because it gives a much fuller idea of the exact form of the skull of an Early Pleistocene man (free from the doubts which arise in the case of a reconstructed specimen), but also because its peculiar features, revealing as they do many points which suggest an affinity with *Pithecanthropus*, associated in the same skull with others such as are known only in the case of the Piltdown skull, form a bond of union between the other two Early Pleistocene skulls, the characters of which hitherto have been supposed to be irreconcilable one with the other

In addition to this, the skull of *Sinanthropus* reveals many features which are unknown in either of the other types and throws a great deal of light upon the characters of the common ancestor of the human family, from which all these genera had been derived One of the most striking illustrations of this fact is the peculiar form of the mastoid region of the temporal bone, recalling as it does the condition found in the new-born child and in the adult anthropoid apes For it lacks that salient character which is so distinctive of the adult human being of other genera

The brain-case found in 1929 is that of a young adult corresponding in the state of its development with the condition found in modern human skulls at about eighteen years of age When the skull was first examined, Prof Davidson Black was impressed by the grace of its contours in comparison with the uncouth outlines of *Pithecanthropus*, and suggested the possibility that it might be female, with the reservation, of course, that the evidence at our disposal regarding this hitherto unknown type of being was altogether inadequate for any definite decision upon this matter

The discovery of another brain-case was made in July 1930 by recovering from material brought in from the Chou Kou Tien cave (in October 1929) a series of fragments which articulated naturally one with the other to form the greater part of the calvaria This discovery of a skull of another young adult of approximately the same age revealed a more lightly built skull with smaller eyebrow ridges, a less prominent forehead, and less obtrusive parietal eminences, which both Prof Davidson Black and I consider to be probably of a different sex from the other skull

One of the most remarkable points of contrast between the brain-case of *Pithecanthropus* and of *Eoanthropus* was the remarkable thickness of the latter, whereas the skull of *Pithecanthropus* was much thinner In the case of the skull of *Sinanthropus* found on Dec 2, 1929, the thickness of the bone (Fig 1) approximates to that of the Piltdown skull Not only does it resemble it in mere thickness, but also the architecture of the cranial vault (which in the case of the Piltdown skull has hitherto been regarded as quite distinctive) is almost exactly reproduced in the case of *Sinanthropus* In all other known human skulls the cranial bones consist of two fairly thick tables united by a comparatively thin layer of diploic tissue consisting of fine trabeculæ In the case of the thick cranial bones of both the Piltdown and the Peking skulls, the tables are relatively thinner, and the thicker layer of diploic bone consists of a very robust network of coarse trabeculæ These similarities suggest that in the thickness and peculiar texture of the cranial bone of two Early Pleistocene skulls of different type

* From the Henderson Trust Lectures (No 11), delivered in the University of Edinburgh on Jan 30

(separated geographically as their habitats were by the whole extent of the continental land mass

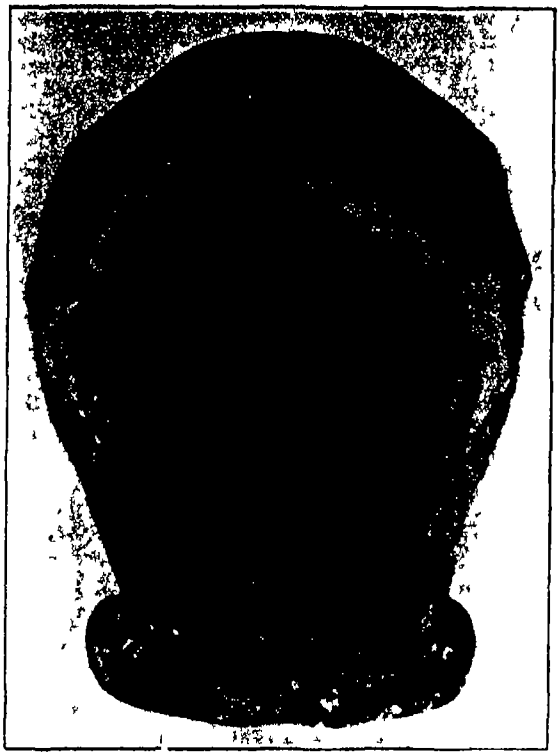

Fig 1 —Photograph of the upper aspect of the Peking skull with part of the roof removed to display the exceptional thickness of the bones and the small size of the brain cavity, which is occupied by a mass of limeston (travertine) The thickness and texture of the skull reveal an unexpected similarity to the conditions found in the Piltdown skull

between England and China) we are dealing with characters of primitive man for which no close analogy can be found in the apes This condition in the Piltdown skull was regarded either as pathological or the result of some freakish mutation But the presence of the same condition in *Sinanthropus* enhances its importance

Why the skull of primitive man should attain such an enormous thickness is difficult to explain but the evidence provides an interesting problem for morphologists to endeavour to solve Did primitive man's skull increase in thickness because the increase in the capacity of the brain-case deprived an increasing area of the protection of the temporal muscles?

For the moment, when there is no clear indication as to the meaning of this peculiar morphological feature, it is of interest as emphatic evidence of the affinity between *Eoanthropus* and *Sinanthropus* and of the enhanced importance of the structural peculiarity itself The contrast in thickness between the cranial vault in *Pithecanthropus* and *Eoanthropus* acquires a new interest in view of the fact that the three (adult) skulls of *Sinanthropus* (one of the fragments found in 1928 is thin because it is part of a child's skull) reveal a considerable range that is sufficient to bridge the gap which separates Piltdown man from the ape-man of Java

The discovery of the two jaws in 1928, presenting as they did features hitherto known only in Piltdown man, raised the possibility that there had been discovered in China a type of human being more closely akin to the Pleistocene man of England than that of the ape-man of Java, who was geographically much nearer to the Peking man When, however, in 1929 the skull was found (and the base was still embedded in the solid mass of travertine) the striking resemblances of the brain-case (Fig 2) to that of *Pithecanthropus* suggested that, after all, the newly found genus was more nearly akin to his neighbour from Java The skull revealed great projecting eyebrow ridges like those of *Pithecanthropus*, which provided a marked contrast to the condition found in Piltdown man, in which such ridges were lacking The front part of the skull was also flattened and ill-filled, and had a prominent median crest such as that of *Pithecanthropus* There was this difference in the frontal region of the bone, however, that the frontal eminences were definitely more obtrusive than those of *Pithecanthropus* Turning to the consideration of the parietal bones, one finds a close resemblance to those of the Piltdown man This resemblance depends both upon the fact that the bones tended to be raised up towards the middle line and are not so flat as those of *Pithecanthropus*, that there is a very definite parietal eminence such as is completely lacking in the Java skull, and that the postero-inferior corners of the parietal bones are everted in that peculiarly distinctive way found in the Piltdown skull The occipital bone again presents a much closer resemblance to that of *Pithecanthropus*, and when we turn to consider the temporal bones we find a much more primitive condition of the mastoid and of the tympanic bones

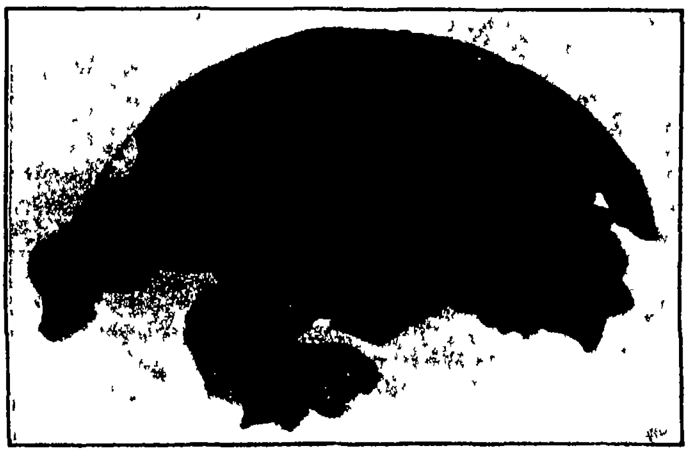

Fig 2.—The left side of a skull of Peking man found in July 1930 It shows the root of the nose and part of the base of the skull which were not present in the specimen found in December 1929, and it reveals certain minor differences from the other skull which have been interpreted as due to a difference in sex

than that which is revealed in *Eoanthropus* Unfortunately the temporal bone of *Pithecanthropus* has not yet been discovered, so that we cannot

institute comparisons between *Sinanthropus* and *Pithecanthropus* in this respect

One of the most interesting features of the specimen found in 1929, a feature which Dr Davidson Black inferred from the nature of the wear of the teeth long before the skull was found, is the fact that the condyloid fossa for articulation with the mandible presents a very close resemblance to the condition found in modern man, in size, depth, and direction This fact is all the more remarkable because in other extinct members of the human family, in particular Rhodesian man and Neanderthal man, there are much more profound differences in the under surface of the temporal bone The attainment of the condition which became a permanent factor in *Homo sapiens* suggests that *Sinanthropus* is a primitive generalised type, and that modern man has retained many of these primitive characters

Looking at the skull as a whole, one can say that its general form is intermediate between the conditions found in *Pithecanthropus* and *Eoanthropus* It enables us to unite into a solid foundation the characters of the three most primitive members of the human family at present known In giving coherence to this knowledge it also enables us to picture the nature of the common ancestor of all three, the as yet hypothetical Pliocene man

The suggestion has been made that the Peking man's distinctive features are not sufficiently pronounced to exclude him from the genus *Pithecanthropus* The whole configuration of the skull, the texture of the cranial bones, the morphology of the frontal, parietal, and occipital bones, as well as the distinctive features of the teeth and mandible, clearly differentiate Peking man from the ape-man of Java, and present a contrast which is so profound as to compel us to accord it generic distinction In many respects it differs from *Pithecanthropus* and resembles *Eoanthropus*, but the contrast to the latter is even more obtrusive It occupies an intermediate position between the two, but is more primitive and generalised than either

It is a very significant phenomenon that at Chou Kou Tien, in spite of the most careful search in the caves during the last three years, no trace whatever of implements of any sort has been found It must not be forgotten, however, that Dr Andersson in 1921 found pieces of quartz in association with the fossil bones, and that in the later stages of the excavation Mr Pei found further examples of this alien material Those who have been searching in vain for evidence of human craftsmanship on this site are being forced to the conclusion that the Peking man was in such an early phase of development as not yet to have begun to shape implements of stone for the ordinary needs of his daily life

Vitamin B

Distribution and Physiology

THE general distribution of vitamin B is now fairly well defined, but the adequacy of different food substances in this respect for different species and the distribution of the various factors in the B complex are still subjects for investigation R H A Plimmer, with W H Raymond, J Lowndes, and J L Rosedale, has examined the comparative vitamin B value of cereals, pulses, and nuts (*Biochem Jour*, vol 21, p 1141, 1927 vol 23, p 545 1929) The preventive method was employed, using pigeons, and the criterion was maintenance for at least 26 weeks All the vitamins required by the pigeon were therefore included in the estimation symptoms of deficiency were paralysis and loss of weight The diets used contained 5 per cent fish meal, white flour or white rice, and the substance under test in varying proportions Dried yeast contained most vitamin of the other foodstuffs, wheat germ was about half as good as the yeast, whole wheat, bran, and middlings contained about a tenth of the amount present in yeast, and other cereals about a twentieth The majority of the pulses and nuts examined contained between a fifth and a tenth of the quantity present in yeast More vitamin B is required for hatching and rearing young than for maintenance Chickens require half as much again as pigeons, rats only about half, the requirements of human beings may be intermediate between those of the pigeon and the rat

A L Bacharach and E Allchorne (*ibid*, vol 22, p 313, 1928) found that the vitamin B content of malted flour was the same as that of the original unmalted flour, but that the malt extract appeared to contain more the experiments were carried out on rats and the effect is attributed to the improvement in appetite brought about by the extract

The content of vitamin B in seeds has been shown to be markedly influenced by the manure applied to the plant, by M J Rowlands and B Wilkinson (*ibid* vol 24 p 199 1930) Two similar plots of grass and clover were manured with an artificial manure and pigs' dung respectively the pigs were fed on barley meal, middlings, and a small amount of a mixture of meat meal rye and wheat embryo bone meal, and cod liver oil The manured patch produced a heavier crop, containing more clover, but the growth on the dunged patch was bigger By preventive and curative growth tests on rats it was shown that the vitamin B content of the seeds from the manured patch was much less than that of those from the dunged patch In further experiments vitamin B was extracted from pigs' dung by means of alcohol

There is evidence that lower organisms can synthesise vitamin B or similar growth factors, and that this synthesis may occur also in the intestinal tract in higher animals Thus, Reader has found that the meningococcus can synthesise a growth factor for a streptothrix, all the vitamin B_1 being previously removed from the medium, and G L Peskett (*ibid*, vol 21, p 1102, 1927) has shown that yeast can synthesise vitamin B_1 Intra-

intestinal synthesis may be the explanation of 'refection' which has been described by L S Fridericia and H Chick and M H Roscoe (see *Lancet*, vol. 1, p 37, 1928) In this condition rats maintained on a vitamin B free diet containing uncooked rice starch passed bulky white fæces, and at the same time were cured of their symptoms and put on weight The fæces contained abundant vitamin The condition appeared to depend on the presence of uncooked starch in the diet and a virus in the intestine

W R Aykroyd and M H Roscoe (*Biochem Jour*, vol 23, p 483, 1929) have investigated the distribution of vitamin B_2 Wheat and maize were poor sources the germ and bran of wheat contained more than the endosperm, but maize germ contained less than wheat germ dried peas also contained little Dried yeast and ox liver and fresh milk were excellent sources, and egg-yolk and dried meat good It was possible to cure rats suffering from the dermatitis of vitamin B_2 deficiency, as well as to stimulate their growth

The physiological functions of the vitamin B complex are incompletely understood in its absence the metabolic processes of the tissues are imperfectly performed, and investigations have thrown some light upon the details of the defects Thus the vitamin is related to both protein and carbohydrate metabolism G A Hartwell has found that young rats die, with engorgement of the kidneys, when the synthetic diet contains 20 per cent edestin and 5 per cent yeast extract, although older animals thrived on the diet even with a lower allowance of yeast (*Biochem Jour*, vol 22, p 1212, 1928) Increasing the amount of yeast extract permitted normal growth the factor responsible was found to be thermostable Caseinogen and egg-albumin required less yeast extract than edestin for normal metabolism

H W Kinnersley and R A Peters have investigated the relation between the lactic acid content of the brain and the symptoms of head retraction in pigeons fed on a diet of polished rice (*ibid*, vol 23, p 1126, 1929 vol 24, p 711, 1930) Using a special technique, it could be demonstrated that birds showing opisthotonos had more lactic acid in their brains than normal birds, and that this increase was most marked in the parts below the mid brain and occurred here first at a time when symptoms were threatening The increase was not observed after cure by a dose of vitamin B_1 concentrate The symptoms appear to be due to this accumulation of lactic acid, and the fact that it is localised indicates that vitamin B_1 is intimately concerned in the intermediary metabolism of carbohydrates, apparently with the oxidative removal of lactic acid In this connexion it might be remarked that H Yaoi found that muscle from polyneuritic pigeons reduced methylene blue more feebly than normal muscle, but that there was no difference in the glutathione contents (*Proc Imp Acad Tokyo*, vol 4, p 233, 1928) Peters in his Harben Lectures has adduced some evidence that vitamin B_2 may be concerned with the mobilisation of water, and that in its absence together with that of vitamin B_1 œdema accompanies the polyneuritis in its terminal stages

C W Carter and A N Drury have examined the nature of the slowing of the heart beat in rice-fed pigeons (*Jour Physiol*, vol 68, *Proc*, p i, 1929): it appears to be due to an overaction of the vagal centres producing a heart block The condition is cured by whole wheat, so that the factor responsible may be that described by Williams and Waterman

G F Marrian, L C Baker, J C Drummond, and H Woollard (*Biochem Jour*, vol 21, p 1336, 1927) noticed changes in the adrenal glands of pigeons starved or fed on rice only, and Marrian has investigated these alterations in more detail (*ibid*, vol 22, p 836, 1928) Hypertrophy was found in inanition, even though vitamin B_1 was given, and in vitamin B deficiency, whether accompanied or not by inanition œdema accounted for half the hypertrophy in inanition The adrenaline content was increased in the latter condition, but was relatively low in vitamin B deficiency It appeared that the hypertrophy in inanition affected chiefly the medulla, and in vitamin B deficiency, the cortex of the gland

It is now well known that vitamin B deficiency is associated with loss of appetite B Sure has made a detailed study of the anorexia in the rat and found that it is promptly cured by the administration of a vitamin B concentrate (*Jour Nutrition*, vol 1, p 49, 1928) The loss of appetite may be associated with the failure of the gut to empty itself, and a decrease in the digestive secretions J L Rosedale and C J Oliveiro (*Biochem Jour*, vol 22, p 1362, 1928) found that in pigeons suffering from beri beri the pancreas failed to form the enzymes required to digest protein and fat

It might be expected that animals suffering from vitamin B deficiency would show derangements of the sexual function H M Evans, however, found that in male rats, provided vitamin E was supplied, fertility was unaffected and sex interest was decreased only a few days before death (*Jour Nutrition*, vol 1, p 1, 1928) In the female rat the œstrous cycle stopped abruptly after about four weeks on the deficient diet, loss of weight followed immediately (A S Parkes, *Quart Jour Exp Physiol*, vol 18, p 397, 1928) Injections of œstrin produced the signs of œstrus during the anœstrus, but without stimulating the ovaries, which had become much atrophied

W Nakahara and E Sanekawa have found that chicken sarcoma and rat sarcoma and carcinoma do not apparently require vitamin B_1, and contain little of it (*Proc Imp Acad Tokyo*, vol 5, p 55, 1929 vol 6, p 116, 1930 *Scient Pap Instit Physic and Chem Res*, vol 10, p 211, 1929) In the first set of experiments, chickens were fed on polished rice and a salt mixture, the livers from healthy birds, and those carrying growths of the Rous sarcoma, were found to contain equal amounts of vitamin B by test on rats, indicating that the tumour did not deplete the birds' store of vitamin In the second set, the rat tumours were fed to pigeons and rats maintained on vitamin B free diets only minimal amounts of the vitamin were found to be present

Obituary.

MR H W MONCKTON

MR HORACE WOOLLASTON MONCKTON, who died on Jan 14, was the son of Col the Hon H M Monckton, a younger son of the fifth Viscount Galway, his mother being a daughter of Sir Thomas Woollaston White, Bart He was born in 1857 and was educated at Wellington College His father built a house there, on land belonging to the College, and here Monckton and his sister continued to live for the rest of his life He also had chambers in the Temple, where he lived when not at Wellington He was called to the Bar in early life and had some practice on the Midland Circuit and at the Parliamentary Bar, and was all his life an enthusiastic member of the Inner Temple Visits to the Yorkshire coast and the gault exposures at Folkestone attracted him to geology when still a boy, and in 1882 he was elected a fellow of the Geological Society and he joined the Geologists' Association in the same year Later he became interested in botany, and was elected a fellow of the Linnean Society in 1892

Monckton's residence at Wellington College naturally gave him an interest in the Tertiary and Gravel Beds of the surrounding districts He was associated with the late Sir W H Herries in the discovery in 1880 of an abundant fauna in the Upper Bagshot Beds, when the railway cutting through the Fox Hills at Tunnel Hill was quite fresh The Upper Bagshot of the London basin had hitherto been supposed to be practically unfossiliferous A series of papers followed dealing with the relative ages and positions of the various exposures of Bagshot Beds, both in relation to the London clay and to the corresponding beds in the Hampshire basin In this discussion the Rev A Irving, Sir Henry Lyons, and others took part The Upper Bagshot of the London basin was practically proved, by its fossil contents, to be the equivalent of the Lower Barton series of Hampshire, in a joint paper published in the *Quarterly Journal* of the Geological Society in 1888 by Mr Starkie Gardner, Monckton, and the late Henry Keeping Monckton also wrote many papers on the various gravel beds, extending his researches to Essex and throughout the south-east of England He acted as joint-editor with Mr R S Herries of the jubilee volume of the Geologists' Association, and contributed the articles on the Dorset coast and (jointly with Mr Osborne White) on Hampshire and the Bagshot district He was an indefatigable leader of excursions of the Geologists' Association and various field clubs Monckton's activities were not confined to England He went annually to Norway for a number of years, and studied especially the glacial phenomena there He organised an excursion of the Geologists' Association to that country, and devoted one of his presidential addresses to the Association to the district round Bergen

Though so long officially connected with the Linnean Society, he did not publish much of botanical interest He made considerable collections of plants, however, and was specially interested in mosses In the few contributions he made on this subject, his idea was to link up botany and geology by making lists of plants growing on particular geological soils

No account of Monckton would be adequate which did not mention the great amount of work that he did in the management of the societies to which he belonged He was vice-president and treasurer of the Linnean Society from 1905 until the time of his death He was at one time treasurer, and several times vice-president, of the Geological Society, and served on its Council for some twenty-five years in all Of the Geologists' Association, he was at various times president, secretary for excursions, and editor of *Proceedings* He also on several occasions acted as recorder of Section C (Geology) of the British Association Sound business instinct combined with legal knowledge made his opinion much sought after, and his advice was generally followed by his colleagues

Besides geology and botany, Monckton was interested in archæology and was an excellent photographer, He made his own slides, and was always ready to give a lantern lecture to the Wellington College boys or others He wrote the volume on Berkshire for the Cambridge County Geographies, and the article on geology in the Victoria County History He was also a fellow of the Royal Numismatic Society and made a carefully selected collection of English silver coins He was a man who will be much missed by many friends, and especially by the sister whom he leaves to mourn his loss

PROF A LEITCH

THE death on Jan 26 of Prof Archibald Leitch, director of the Research Institute of the Cancer Hospital, following in less than a year the loss of Dr H J B Fry of the same laboratory (see NATURE, May 31, 1930), leaves a woeful lacuna in the ranks of cancer research Born in 1878, Leitch was educated at Rothesay Academy and the University of Glasgow, where he had a distinguished record in arts and medicine, graduating in 1902 He soon devoted himself to pathology, acting as assistant in the Cancer Research Laboratory of the Middlesex Hospital From London he passed to Dundee as director of the Caird Research Laboratory, a post he occupied until his return to London as pathologist to the Cancer Hospital, becoming director of the Research Institute a few years before the War During the War, Leitch was in charge of a Mobile Laboratory, retiring with the rank of Major, R A M C (T F)

Leitch's most productive period fell in the succeeding years, when renewed interest in carcinogenetic studies followed the pioneer investigations of Fibiger, for whom his admiration was intense, and Yamagiwa His best-known contributions to knowledge in this domain dealt with the carcinogenic action of lubricating oils and the causation of mule-spinners' cancer, and he served on the

Home Office Committee appointed to inquire into this disease

Of greater theoretical importance was Leitch's demonstration of the carcinogenic action of arsenious acid, and the fact that this factor was not responsible for the carcinogenic action of tar He also showed that in the production of tar cancer in mice, the essential damage was completed before the appearance of proliferative changes in the skin, although a relatively long latent period might elapse before definite tumour development supervened This important observation has revolutionised our earlier attitude to the problems of compensation in occupational cancer

Leitch's numerous publications are characterised by a careful and polished diction, enlivened from time to time by striking and appropriate phrases, which betrayed his literary and classical learning and training He was an able and attractive speaker, and many of his addresses on formal and informal occasions were enlivened by a wealth of appropriate anecdote He leaves a widow and four children, to whom will be extended the sympathy of his co-workers at home and abroad

J A Murray

Mr R G Lunnon

Robert G Lunnon, who died on Jan 25 at the age of forty years, was widely known both for his scientific and for his humanitarian work He was educated at Tottenham County School and University College, London, where he held the Neil Arnott Scholarship of the University of London, and after graduating was appointed to a lectureship in the department of applied mathematics During the War he served in France with the Red Cross and later was engaged in relief work for refugees in Holland

In 1919, Mr Lunnon was appointed lecturer in physics at Armstrong College, Newcastle, where he remained to the time of his death His work there gave full scope to his many abilities In addition to his departmental duties, which he discharged with conspicuous success, he undertook a great deal of work on behalf of the students, and had acted since 1926 as senior tutor in the Faculty of Science His colleagues were also greatly indebted to him for his work in connexion with the Association of University Teachers, both as secretary and representative on the council He attended the meetings of the British Association regularly, and served on the committee of Section A

Mr Lunnon's published papers relate to a variety of topics, the best known being a series on the motion of spheres in fluid media, which gave evidence of mathematical and experimental ability of a high order Although extremely active in academic and scientific work, he yet found time for a great deal of social service in various forms These are too numerous to detail, but the cause of international goodwill was perhaps the one nearest his heart, and he laboured to promote it with all the enthusiasm and energy that was in him His students, his colleagues, and his many friends will always remember him with gratitude as one who had great gifts and used them to the full—but always on behalf of others

We regret to announce the following deaths

Sir Andrew Balfour, K C M G, director of the London School of Hygiene and Tropical Medicine, on Jan 30, aged fifty seven years

Dr W E Johnson, Sidgwick lecturer in moral philosophy in the University of Cambridge, and author of a work on "Logic", three volumes of which out of the four contemplated have been published, on Jan 14, aged seventy two years

Prof Orazio Marucchi, professor of archæology at the University of Rome and director of the Vatican Egyptian Museum, on Jan 21, aged seventy seven years

Dr R B Moore, formerly chief chemist of the U S Bureau of Mines and recently professor of chemistry in Purdue University, who was known for his work on radioactivity, applied chemistry and metallurgy, aged sixty years

Dr J Perrin Smith, emeritus professor of palæontology at Stanford University, with which he had been connected since 1892, on Jan 1, aged sixty six years

News and Views.

The causes of the present agricultural depression in Great Britain are reviewed by Mr C S Orwin, director of the Institute for Research in Agricultural Economics at Oxford, in an article in the *Political Quarterly*, vol 2, No 1, entitled "The Agricultural Problem" Although the assertion that in previous years wages have been based entirely on the price of wheat is probably an over-statement, it is evident that at the present time wages are fixed with reference to a standard of living regardless of the condition of the industry, and the fact that the necessity for paying a statutory wage continues, while the guarantee for prices has been withdrawn, constitutes one of the farmer's chief complaints From a comparison of the costs of production of such commodities as wheat, mutton, and milk for the years 1914, 1925, and 1930, it appears that for the two earlier years the corresponding figures were almost identical, and even in 1930 the cost of production has only risen appreciably in the case of wheat The problem is, therefore, mainly one for the arable farmer, but the obvious course of abandoning corn growing in favour of the more profitable industries is no solution for the eastern districts, where climatic conditions are unsuitable for dairying or market gardening, and further, the transformation of these areas into sheep farms could only be done at a great sacrifice of employment and production

The solution of the present agricultural problem, Mr Orwin thinks, lies in a readjustment of the principles underlying arable farming In the first place he questions the advisability of continuing mixed farming, which includes the production of both corn

and meat Times have changed since man was entirely dependent on farmyard manure for the growth of his crops The labour involved in its production and the cost of internal farm transport he regards as unnecessary, whereas an interdependent system of live stock and corn farming might prove quite economical In another aspect also, a break with tradition is recommended Farm and fields were originally laid out in sizes convenient for horse labour, but with the development of the tractor and other forms of mechanical power, some readjustment of areas is needed for efficient working The argument that such an industrialisation of agriculture will only aggravate the unemployment problem is ruled out, as much poor grass land could be profitably used for corn growing if only the cost of production could be reduced A warning is added of the danger of over production if farmers rely solely on those branches of the industry which tend to be profitable at the moment, and emphasis is laid on the necessity for fundamental reorganisation if the solution of the present problem is to be permanent

The trustees of the London Museum have made a new departure in museum work by instituting a studentship for the encouragement of research in some subject germane to the interests of the museum They have been enabled to take this step through the generosity of Viscount Esher, who has placed at the disposal of the trustees the sum of £300 per annum as a memorial to his father, the late Lord Esher, one of the founders of the museum The studentship will be awarded "for the purpose of promoting research into some aspect of the history or archæology of London, whether by documentary research, by excavation, by museum work, or by a combination of these methods" The award will be made by the trustees on the recommendation of an advisory committee, on which representatives of the Society of Antiquaries, the British Academy, and the universities of Oxford, Cambridge, and London will serve, and the tenure will be normally for a period of two years The researches of the student will be incorporated in a thesis, which may, in due course, be published at the direction of the trustees It is hoped that, in the course of years, a very substantial amount of useful and original material bearing directly or indirectly upon the arts, crafts, and history of the metropolis will be collected The scheme may be regarded as an interesting experiment in the development of that extra mural work which is now regarded as appropriate to our national museums Entries for this studentship are invited on or before Mar 14

Towards the end of last month several earthquakes were recorded at Kew Observatory On Jan 27, at 8 h 20 m 59 s P M, the first vibrations of a great earthquake reached Kew, from a centre in about lat 26° N, long 98° E, or near the south west border of China Of this earthquake no direct news has yet come or is likely to come A few hours later, at 5 h 59 m 37 s A M on Jan 28, there was another, though of much less importance, with an origin about 1260 miles from Kew no doubt the same as that reported in the *Times* for Jan 29 as having caused much damage and some loss of life at Koritza in Albania, one of the most active earthquake centres in that country At 9 h 43 m 6 s P M on the same day an earthquake of moderate intensity was recorded with its epicentre in about lat 7° N, long 142° E, or in the western Pacific to the north of New Guinea. The U S Coast and Geodetic Survey (according to a *Daily Science News Bulletin* issued by Science Service, Washington, D C), with the aid of fourteen seismograms, has estimated the position of the Mexican earthquake of Jan 14 to be in lat 16° N, long 96° W, or close to the coast of the Gulf of Tehuantepec, and also to the origin of another destructive earthquake on Mar 22, 1928 An earthquake of great intensity occurred in North Island, New Zealand, on Feb 3 The first shock was noted at 8 51 A M, and shocks continued for two hours The epicentre appears to have been submarine and in the vicinity of Napier, which has a population of 19,000, and the main portion of the city has collapsed A heavy death roll is estimated in Napier and for many miles around A sea wave followed the earthquake

In his presidential address to the Royal Microscopical Society delivered on Jan 21, Prof R Ruggles Gates reviewed certain aspects of the history of the Society showing its importance in the development of biology, and cited some of the eminent scientific men who had taken part in its work Prof Gates then discussed adaptations in cell structure He cited various cases of complicated structures in the Protozoa, and referred to the widespread occurrence of cilia in many animal and plant cells The mechanism of mitosis or nuclear division was treated as an adaptive mechanism which originated very early in evolution and made possible the multicellular structure of higher organisms, at the same time serving to perpetuate many of the differences arising through variation The capillitium in Mycetozoa and puff balls, the elators of Liverworts and of *Equisetum*, were discussed as examples of evolutionary adaptation, arriving at the same goal by different paths The development of the spiral markings in wood cells was explained, and the long, coiled suspensors of Conifer embryos were treated as a study in adaptation and over specialisation through competition between the young embryos and the principle of developmental selection The frequency of parallel mutations in the evolutionary development of many cell structures was emphasised, and it was shown that the principles of adaptation in cell structures are the same as in the development of adaptations in the organism as a whole

For his lecture on the beginnings of tropical medicine, before the London School of Hygiene and Tropical Medicine on Feb 3, Dr P Manson Bahr chose the life and work of Patrick Manson as the chief topic Patrick Manson, to whom the London School of Hygiene and Tropical Medicine owes its inception and its very existence, was one of the most original and outstanding medical personalities of the last century Not only did he himself make many original and lasting discoveries in the field of medicine, but also he

laid the foundations of the science of tropical medicine. Born on Oct. 3, 1844, he graduated at the University of Aberdeen in 1865, and then proceeded to Formosa and worked there as well as in Amoy, China, for ten years before seriously interesting himself in the scientific side of medicine It was in 1875 that he first saw the microscopic embryo filaria in the blood of the local Chinese, and it was in the elucidation of the life history of this parasite that he first achieved everlasting fame He was the first to recognise that this small worm was to be found in countless numbers in the blood at night time, and recognised that its peculiar habits and structure were adapted to a second life in the body of a mosquito This insect he proved to be an essential intermediary in its transference from one human being to another and in its growth into an adult worm, which was afterwards found to inhabit the lymphatic tissue and to attain the length of nearly two inches In 1892 he commenced to study malaria seriously, and deduced the probable life history of this parasite from what he had already ascertained to be the case in the filaria In 1894 he formulated his mosquito-malaria hypothesis and became associated with Ronald Ross It was the outcome of this ideal collaboration which resulted in the verification of the complete cycle of the malaria parasite in the Anopheles mosquito in 1898 In 1897 Manson became medical adviser to the Colonial Office, and became intimately associated with Joseph Chamberlain in schemes for the betterment of health conditions in the Colonies The first outcome of this collaboration was the foundation of the London School of Tropical Medicine in 1899

DR G A REISNER, director of the joint expedition of the Boston Fine Arts Museum and Harvard University in Egypt, has recently given an account at Cairo of his excavations in Giza Cemetery and the Pyramid area, and summarised the evidence bearing on the development of Egyptian ideas on the life after death and the cult of the dead in the Old Kingdom A report of two lectures, delivered on Jan 16 and 20, is given by the Cairo correspondent of the *Times* in the issue of Jan 31 The Egyptian tomb consisted of two parts, the burial chamber and the offering place, the former being originally a square pit excavated in the gravel, which developed finally into a stone mastaba or pyramid The construction of the pyramids in the great cemetery of Giza, founded by Cheops, the second king of the fourth dynasty, employed tens of thousands of men on unproductive labour, and by the end of that dynasty the population was supporting a large body of priests to feed the dead of centuries The funerary priest was a civil functionary who, as a result of contact with an individual, became the servant of his *ka* By a contract, the functionary and his heirs in perpetuity became owners of land, in return for maintenance of offerings in the funerary chapel of the dead The pyramid cities housing these functionaries, who enjoyed immunity from taxation and forced labour, were crowded with inhabitants In tracing the development of other features of the cult—the slab stelæ, the wall paintings, the festivals of the dead, and so forth—Dr Reisner sketched a remarkable picture of the Cemetery of Giza as a city of living spirits whose daily needs were supplied by the living servants they had engaged while themselves still living

THE Electricity Commissioners held an exhaustive public inquiry on the application of the Fulham Borough Council for permission to extend its Townmead Road generating station Judging by the rapid and increasing demand for electric power in the south-east England area, there could be no question about the usefulness of this station , but there was considerable opposition on the ground that it would seriously affect the amenities of the neighbourhood It was suggested that the required power could be obtained by building a new power station on the lower reaches of the Thames If this were done, a transmission system at least 18 5 miles long would have to be provided Numerous high tension cables would therefore need to be provided, and a survey showed that it would be very difficult, if not impossible, to find room for these cables, owing to the existing congestion under the streets The alternative method of laying cables along the bed of the Thames was not considered practicable The loss in transmission due to heating the cables would be about £150,000 a year, and there would in addition be very heavy capital charges To make extensions by building a number of small stations would about double the cost The Commissioners came to the conclusion that any nuisance arising from the emission of grit and sulphurous fumes could be obviated by the installation of modern devices By observing also the conditions laid down by the Port of London Authority, the effluent from this plant can be rendered harmless Assuming that the Fulham Borough Council take the best known precautions for the due consumption of smoke and for preventing so far as reasonably practicable the evolution of oxides of sulphur, the Commissioners gave their consent to the proposed extensions on Jan 27

IT seems highly probable that in a few years' time much of our electric lighting will be done by incandescent gases in luminous tubes and not by incandescent filaments This kind of lighting is generally referred to as neon lighting, but argon, helium, krypton, and other gases are used Although Lord Rayleigh and Sir William Ramsay were the first to separate these gases from the atmosphere, yet the commercial development of them for lighting purposes is mainly due to Georges Claude in France There are now about a hundred companies in various parts of the world exploiting his patents and all bound together by an agreement to interchange technical information and research results. All the countries concerned have a common interest in advancing the science of tubular lighting In the December *Journal* of the Junior Institution of Engineers an abstract is given of a lecture by H Marryat describing many of the recent advances that have been made In the Paris factory the great difficulties in the way of introducing a minute quantity of an absolutely pure gas into an

absolutely clean tube were finally overcome by the introduction into the factory of the methods of the precise scientific worker Neon tubes are familiar in London from being used for advertisement lighting The original voltage used was 32,000, but it has now been reduced to 1000, and tubes have been made in the laboratory that will work at 200 At present their most important use is for the lighting of aerodromes and air routes The light from Croydon beacon can be seen by airmen when flying over France Luminous signals are employed to indicate to the pilot the velocity of the wind and its direction at ground level, so that he may alight against the wind at the correct speed For domestic lighting, however, we have to await the commercial development of the white tubular light, which laboratory experiments have shown to be a very desirable one

In the *Westinghouse International Journal* for January there is an interesting account of a device for controlling traffic which is being adopted in several towns in the United States and is a modification of the 'Stop and Go' light system In many main streets the traffic is always heavier than on a little-used intersecting street, hence the traffic may be held up in the main street although there are no vehicles using the side street In order to obviate this drawback, a device is used in connexion with the 'Stop and Go' light whereby the latter only shines red down the main street when a motor vehicle approaches the intersection from the side street The device is based on the principle of the photo electric cell, and is mounted on a pedestal three feet above the curbstone in the side street, near the crossing When a vehicle approaches from the side street it necessarily has to stop, and in this position it intercepts a beam of light which falls on a device called the 'electric eye' The interruption of this light beam automatically changes the visible signal facing the side street from red to green and the signal in the main street from green to red for an interval long enough to enable the motorist to cross the main street This device enables the traffic speed to be greatly increased, and is working well in everyday use

Dr J Robinson, formerly chief of the Radio Research Department of the Royal Air Force, has invented a system of multiplex telegraphy A demonstration of it was given on Jan 20, at the offices of the *Daily Mirror*, using a line to Bristol and back, a distance of about 240 miles The line was specially lent by the Postmaster-General for the development of the method, and both sending and receiving instruments were in the same room The main advantage claimed for the method is that by its use more than twice as many messages as are now possible can be sent simultaneously over one wire In England only six channel frequencies are employed, but in America twelve are sometimes used The stenode radiostat system uses a separate audible frequency for each of the messages sent The transmission is carried out by modulating each audible frequency at a speed which is determined by the speed of sending It is claimed that with this type of receiver the broad spacing of the frequencies made necessary in practice to avoid overlapping has been considerably reduced. The selectivity of the instrument is due to the successful use of tuning-forks as electrical filters At the demonstration, the channel frequencies were placed apart by only a hundred cycles a second At this spacing, communication of 80 words a minute was carried out

Dr F S Sinnatt, deputy director of fuel research, in a public lecture delivered on Feb 2 at the Sir John Cass Technical Institute, E C 3, gave an account of the work being carried out by the Coal Survey, which is one item in the programme of work of the Fuel Research Division of the Department of Scientific and Industrial Research The Survey is undertaking a systematic investigation of the coal seams of Great Britain, and in order to carry out the work committees have been appointed in all the major coalfields of the country and laboratories have been established at convenient centres The work is now in progress in Scotland, Northumberland and Durham, West Yorkshire, South Yorkshire, North Staffordshire, Nottinghamshire and Derbyshire, and South Wales, while a laboratory is being equipped to serve the coalfields of Warwickshire, Cannock Chase, and South Staffordshire Upon the technical side the investigations are carried out by obtaining a solid pillar of coal representing the whole thickness of the seam, and transporting this to the laboratory, where it may be investigated in detail Certain parts of the analyses are carried out rapidly so as to prevent changes due to oxidation, etc, and the seam is then examined for its physical characteristics and, if necessary, divided into a number of layers, depending upon the character of the seam Samples of the various coals are obtained and submitted in the first instance to proximate analysis, together with the estimation of sulphur and the determination of the calorific value The broad properties of the seam are then reviewed, and after consultation with the staff of the colliery the number of layers which will be examined in greater detail is decided upon The seam as a whole and the various layers are then examined exhaustively It is the object of the survey to trace the variations of the seams throughout the coalfield, and to correlate with this change in properties the possible effect they will have upon the way in which the seam is utilised commercially

Sir J. J Thomson will receive the Dalton Medal of the Manchester Literary and Philosophical Society when he delivers the Dalton Lecture before the Society on Mar 17, 1931

The Second Pedler Lecture of the Chemical Society, entitled "Studies on Biological Oxidation", will be delivered by Prof. H Wieland, of Munich, on Friday, Mar 6, at 5 30 P M, in the meeting hall of the Institution of Mechanical Engineers. Admission is free, without ticket

The second course of Scott Lectures at the University of Cambridge will be delivered by Dr. Irving Langmuir, of the Research Laboratories of the General

Electric Company, Schenectady, N.Y., in the Cavendish Laboratory, at 4.45 P.M., on Feb. 9, 11, 13, 16, and 18. The subject for this course is "Fundamental Phenomena in Electrical Discharges in Gases." The lectures are open without fee to all members of the University.

THE University of St. Andrews has sent its congratulations to Dr. W. W. Keen, of Philadelphia, one of its honorary graduates, on his attainment, on Jan. 19, of the age of ninety-four years. It is twenty-three years since Dr. Keen resigned the professorship of surgery at Jefferson Medical College. The honorary degree of LL.D. was conferred upon him by the University of St. Andrews in 1911, during the celebration of the five-hundredth anniversary of the foundation of the University. Dr. Keen's longevity and cheerful hardihood are matched by those of emeritus Prof. W. C. M'Intosh, also of St. Andrews, who is ninety-two years of age and is still busy with scientific work.

THE following committee has been set up jointly by the First Commissioner of Works and the President of the Board of Education, to consider the recommendation of the recent Royal Commission on National Museums and Galleries that a national folk museum should be established, if possible, in London, and also to advise as to the practicability and cost of establishing such a museum: Sir Lionel Earle (chairman), Mr. E. R. D. Maclagan, Mr. E. S. Makower, Sir Henry Miers, Prof. J. L. Myres, Mr. C. R. Peers, Sir Henry Richards, and Dr. R. E. Mortimer Wheeler. The secretary is Mr. E. F. Muir, Ancient Monuments Branch, Office of Works, London, S.W.1.

AT the annual general meeting of the Royal Microscopical Society, held on Jan. 21 at B.M.A. House, Tavistock Square, W.C.1, the following officers and new members of council were elected: *President*—Prof. R. Ruggles Gates; *Treasurer*—Mr. Cyril F. Hill; *Secretaries*—Mr. J. E. Barnard, Dr. Clarence Tierney; *New Members of Council*—Mr. C. Beck, Mr. G. R. Bullock-Webster, Prof. R. T. Hewlett; *Librarian*—Dr. Clarence Tierney; *Curator of Instruments*—Mr. W. E. Watson Baker; *Curator of Slides*—Mr. E. J. Sheppard.

THE provisional figures of the vital statistics for England and Wales for 1930 have been issued by the General Register Office. The rates per 1000 population were: for births, 16.3, the same as for 1929, which was the lowest recorded; and for deaths, 11.5. The death rate is 1.9 below that for 1929, and is the lowest recorded, being 0.1 below the rates for 1923 and 1926, the previous lowest. The infant mortality rate (deaths under one year per 1000 live births) was 60, and was also the lowest on record, being 5 per 1000 below that for 1928, the previous lowest, and 14 per 1000 below that for 1929.

MESSRS. Flatters and Garnett, Ltd., of Manchester, have issued a new catalogue of lantern slides illustrative of the various branches of science. There is a very wide range of types amongst this collection, from plain and coloured photographs of geological interest to macroscopic pictures of plants and microscopic photographs and diagrams of Protophyta and Protozoa. The list in all branches, and especially that of botany, has been greatly enlarged. This is due chiefly to Mr. Flatters, who is especially interested in the study of plants from the anatomical and histological point of view. Messrs. Flatters and Garnett, Ltd., take full advantage of the fact that their establishment is close to the University of Manchester. Members attend the public lectures, meetings, and exhibitions which are held in the University, and their assistants are sent to the evening course in biology. Thus much valuable information with regard to the production of lantern slides, the type required, the arrangement of lists, and so forth, is obtained. The lantern slides produced by Messrs. Flatters and Garnett, Ltd., are invaluable assets to the public lecturer, the university lecturer, and the school teacher.

MESSRS. W. Heffer and Sons, Ltd., Cambridge, will publish shortly "The Scientific Detective and the Expert Witness", by Dr. C. Ainsworth Mitchell, which work aims at giving a more or less popular description of the methods by which those with specialised training have been able to assist in solving problems constantly arising in criminal investigation.

THE Museum of Comparative Zoology at Harvard University announces that the first volume of a check list of the birds of the world by James Lee Peters is now in press and will be issued shortly. The classification followed for the higher groups is that proposed by Dr. Wetmore, with the sequence of genera and species according to the author's own ideas where no authoritative treatment has been published. The first volume will contain about three hundred genera and one thousand seven hundred species and subspecies. It is expected that at least ten volumes will be required to complete the work. The second volume is in active preparation and preliminary work on others is under way. The new check list is not a Museum publication and will not be distributed to the Museum's exchange list, but will be sold by the Harvard University Press.

APPLICATIONS are invited for the following appointments, on or before the dates mentioned:—A professor of anatomy in the Madras Medical College and a professor of anatomy and physiology in Vizagapatam Medical College—The High Commissioner for India, General Department, India House, Aldwych, W.C.2 (Feb. 10). A principal of the Acton Technical College—The Secretary (F), 10 Great George Street, Westminster, S.W.1 (Feb. 14). A museum assistant in the Leicester Museum and Art Gallery—The Director, Museum and Art Gallery, Leicester (Feb. 16). Inspectors under the Ministry of Agriculture and Fisheries, for the purposes of the Diseases of Animals Acts, 1894–1925—The Secretary, Ministry of Agriculture and Fisheries, 10 Whitehall Place, S.W.1 (Feb. 16). A temporary assistant mycologist under the Department of Agriculture for Scotland, for work in connexion with bracken disease—The Establishment Officer, Department of Agriculture for Scotland, Queen Street, Edinburgh (Feb. 16). A principal of

the Kingston upon-Thames Technical College—The Secretary, Education Department, County Hall, Kingston upon Thames (Feb 21) Inspectors under the Board of Education, for technical and evening schools—The Secretary, Board of Education, Whitehall, S W 1 (Feb 21) A senior lecturer in physics in the University of Cape Town—The Secretary, Office of the High Commissioner for the Union of South Africa, 73 Strand, W C 2 (Feb 24) A University reader in mathematics at Westfield College—The Academic Registrar, University of London, South Kensington, S W 7 (Feb 27) A lecturer in physics at Armstrong College — The Registrar, Armstrong College, Newcastle-upon-Tyne (Mar 5) Assistant examiners in the Patent Office — The Secretary, Civil Service Commission, Burlington Gardens, S W 1 (June 4) A temporary science master at Merchant Taylors' School, for chemistry (or possibly physics) during May, June, and July—The Headmaster, Merchant Taylors' School, Charterhouse Square, E C 1 A Grade "E" technical assistant in the Signals Experimental Establishment — The Superintendent, Signals Experimental Establishment, Woolwich Common, S E 18 An advisory veterinary officer at Reading University, for the Southern Province—The Registrar, The University, Reading.

Our Astronomical Column

Registration of Solar Prominences—In a recent issue (No 88) of the *Bulletin* of the Kodaikanal Observatory—a biannual publication containing current observations of solar prominences and disc phenomena recorded spectroscopically at Kodaikanal—the Director, Dr T Royds, directs attention to the publication of additional data of prominences photographed in hydrogen light (Hα) There are two spectroheliographs in daily use at this observatory, one of which is used for obtaining composite photographs showing the disc markings and the prominences at the sun's limbs in calcium light (K), whilst the other instrument is employed for registering the disc markings in hydrogen (Hα) light Owing to the increased speed of panchromatic plates, it has been found possible to include in the daily programme since Jan 1, 1929, the registration of the prominences in hydrogen light Dr Royds finds that the mean daily areas of Hα prominences in 1929 are considerably less, about 54 per cent, than those of the calcium prominences This, he points out, is not necessarily to be interpreted as evidence that the hydrogen prominences are less extensive or less high than calcium prominences, for there are numerous examples where individual prominences are identical in shape, height, and area in the Hα and the K photographs There is, however, considerable evidence that in the fainter and more scattered parts of K prominences the Hα counterpart is relatively much fainter when compared with the brighter parts of the prominence This is not a photographic effect caused by the under exposure of the Hα plate, for whilst the main part of a prominence may be stronger in the Hα photograph than in the calcium, the reverse is often true in the fainter parts of the same prominence The exact relations between the relative intensities in different parts of Hα and K prominences require further study, and it is very satisfactory that data for this purpose will be accumulated at Kodaikanal

Rotation Period of Uranus—The two most trustworthy determinations of this period were those made by Profs Lowell and Slipher at Flagstaff in 1911 and that of Mr L Campbell in 1917, the former was spectroscopic, the latter by light variation The results were practically identical, $10^h\ 50^m$ and $10^h\ 49^m$ respectively But there was considered to be room for a further investigation, since the indicated probable error of the spectroscopic method was 17 minutes, and the light variation was not confirmed by several other observers It may, however, have been produced by a temporary marking *Pub Ast Soc Pac* for December contains an account of a new spectroscopic determination made by Messrs Moore and Menzel They used a higher dispersion than Lowell and Slipher, also the equator of Uranus is more nearly central on the disc Their weighted mean is $10^h\ 50^m$ with a probable error of 10^m, but in spite of the close accord with the previous results, they do not consider that the period is certainly known within several minutes, Mr Moore's results, taken alone, give $11^h\ 18^m$ and those of Mr Menzel $10^h\ 26^m$ The uncertainty arises from the small size of the disc of Uranus It will be remembered that in their Neptune investigation they estimated the uncertainty as a full hour

The *Gaz Astron* for January announces that M V Tshernov has been making photometric observations of Uranus during the autumn of 1930 He finds for the period of rotation $10^h\ 47^m\ 34^s$ Before opposition the range of magnitude was from 5 97 to 6 16, after opposition, from 5 78 to 6 10

The Radial Velocities of the Spiral Nebulæ—Prof. C D Perrine notes in *Astr Nach*, No 5754, that radial velocities of recession approaching 10,000 km/sec have been deduced at Mount Wilson for some of the faint distant spirals He makes the suggestion that the annual aberration of these objects should be compared with that of neighbouring stars, according to former ideas, since these bodies are receding with a velocity one thirtieth of that of light, the velocity of their light-waves relatively to the observer would be less than that of the stars in the same proportion Hence the constant of aberration for them should be greater than for the stars by 0 7″, a quantity easily measurable on good photographs

According to Einstein's theory the apparent velocity of the light is constant for all objects But just as observations of the Einstein shift of stars near the sun are still made during total eclipses, it would seem to be worth while to make this experiment in order to test the theory further Photographs should be taken as nearly as possible at the times when the objects are at the two ends of the major axis of the aberration ellipse

Minor Planets—*Kleine Planeten* for 1931 (published by the Berlin Rechen Institut) indicates that there are now 1152 numbered planets, five of those discovered in 1930 having been already numbered. Many planets that were long missing have been picked up, and there are now only five planets in the first 400 that have been lost since the year of their discovery Many new names have been given, the seventh Trojan planet, discovered in 1929, has been named Odysseus The names Probitas, Perseverantia, and Hilaritas have been given to three planets discovered by the late Dr Palisa of Vienna, being regarded as expressing qualities of his character A group of planets are named after flowers Begonia, Camellia, Petunia, Primula Planet 1134 is named Kepler

Research Items.

A Hand-Axe from East Anglia.—Mr. J. Reid Moir, in *Man* for January, figures and describes a hand-axe found last November in the Upper Chalky Boulder Clay at Ipswich. It was dug out of solid clay at a depth of 2½ ft. It was in two pieces, which lay about 15 in. apart. The fracture was ancient and had been caused by thermal action along the line of a weakness in the flint, without doubt at the time of the deposition of the boulder clay. The specimen is typical of the implements found in the Upper Chalky Boulder Clay. In colour it is greyish-black, and shows no sign of patination or abrasion. There are a few ancient striations. The flaking is all of one period. Greatest length $4\frac{3}{16}$ in., greatest breadth $2\frac{13}{16}$ in., greatest thickness $1\frac{1}{16}$ in., and weight approximately 8½ oz. There is now a large body of evidence to show that the Upper Chalky Boulder Clay of East Anglia, representing the third glacial period of this part of the country, was laid down at the close of the Early Mousterian epoch. The flint implements found in the boulder clay have all been derived from other and older deposits torn up by the glacier in its advance. In certain parts of East Anglia sites have been discovered where these deposits have escaped destruction and they have been shown to contain artefacts such as occur in the boulder clay which overlies them. These pre-Upper Chalky Boulder Clay deposits are usually in the form of brick earth such as have been excavated and studied at Ipswich, Hoxne, and High Lodge. In each of these cases the Upper Chalky Boulder Clay overlies the brick earth and in the latter deposit at Hoxne and High Lodge have been found hand-axes of precisely the same type and workmanship as that now described. One found by Mr. Reid Moir at Hoxne in an Early Mousterian floor at the base of the brick earth under the glacial bed laid down by the Upper Chalky Boulder Clay glaciation is almost a duplicate of this specimen. It may now be said that the Early Mousterian period in East Anglia was succeeded by the third glaciation in that area and that *in situ* in the Upper Chalky Boulder Clay which was then laid down derived flint implements of the Early Mousterian epoch have been unearthed.

Treatment of Trypanosomiasis.—Dr. Louise Pearce has written a critical review entitled 'The Treatment of Human Trypanosomiasis with Tryparsamide' (Monograph No. 23 of the Rockefeller Institute for Medical Research). Tryparsamide is the name given to the sodium salt of *N*-phenylglycineamide-*p*-arsonic acid, a compound developed at the Rockefeller Institute for Medical Research during the course of chemotherapeutic investigations on certain protozoan infections. It has the advantage of being very soluble in water and may be administered intravenously, intramuscularly, or subcutaneously with satisfactory effects. The dose is usually 2 gm., and the amount required for the treatment varies from 15 gm. to 25 gm. for early cases up to perhaps 100 gm. for advanced cases. The only untoward effect noticed has been visual disturbances in some 5 per cent of the cases, which is more or less permanent in 1·8 per cent of the cases. The present analysis deals with the results obtained in 1197 cases of sleeping sickness with *Trypanosoma gambiense* infections, of which 96 were considered to be early cases and 1101 late ones. Of the early cases, some 96 per cent appear to have been cured by the drug. Of the 1101 advanced cases, 646 (58·7 per cent) appear to be cured, 272 (24·7 per cent) were improved, and 183 (16·6 per cent) were failures. The results obtained with tryparsamide appear to be vastly superior to those observed with any other drug. Several other papers which have appeared since this analysis was written are also reviewed, and a bibliography is appended.

Fresh-water Mussels Raised in the Laboratory.—The *Daily Science News Bulletin*, Science Service, Washington, D.C., of Nov. 21 announces that Dr. M. M. Ellis has discovered a method of speeding up the development of fresh-water mussels. In its natural environment the mussel spends the first four to six weeks of its life as a parasite on a fish. Dr. Ellis has found a nutrient medium to take the place of the fish in which the mussel is able to develop. After spending a certain time in the medium, the mussels important economically for the making of pearl buttons may be planted out in the rivers which have been depleted by pollution. The raising of these molluscs will be undertaken at the University of Missouri in the new laboratory space just provided by the University for the use of the U.S. Bureau of Fisheries.

Biology of the River Wharfe.—F. Percival and H. Whitehead have already done good work in connexion with Yorkshire streams and rivers. Their recent paper, "Biological Survey of the River Wharfe. Introduction and Report on the Invertebrate Fauna" (*Journal of Ecology*, vol. 18, No. 2, Aug. 1930), records investigations arising out of meetings of the research committee of the Yorkshire Naturalists' Union, in which the River Wharfe, being practically unpolluted, was decided on as a subject requiring detailed examination. Three stations representing the three main physiographic regions through which the river flows, were worked monthly over a period of one and a half years, and in addition subsidiary collections and observations were made at other stations. A net with a mesh of 0·5 mm. was chiefly used, allowing a number of small creatures to escape. Therefore some groups such as the Protozoa, Nematoda and Rotifera have been omitted. Insects are the most important and are dealt with fully. The station at Ulleskelf, where the river becomes affected by tides, is markedly different from the others. The great majority of the species from all the stations require water well charged with oxygen. The environmental conditions and dominant invertebrates are given for each station, and notes on the different groups show details of distribution, habitat, and breeding seasons. There seems to be little seasonal variation in the faunas except those related to breeding and life-cycles. Most of the insects produce eggs from March to October. General conclusions of a preliminary nature are that the various types of stream bed can be approximately classified according to their structure and fauna, and that the variation in number of organisms is due in part, at any rate, to the nature of the life-cycle, to the effect of temperature, and to the amount of rainfall both during the previous breeding season and at other times, and the amount of flooding, of erosion, and general disturbance of the river bed.

Genetics of Field Mice.—Dr. F. B. Sumner has contributed a further account of his well-known investigations on the geographical sub-species of the field mouse, *Peromyscus* (*Jour. Genetics*, vol. 23, No. 2). It is unfortunate that these important researches, which he has carried on at the present Oceanographical Laboratory in Southern California for more than fifteen years, are now to be discontinued, for they represent the most extensive study yet made of the natural sub-species in any mammal. We have

received from Dr. Summer a request to point out two errata which occur on p. 307 of the present paper. In line ten, "$(4/5)'$" should read "$(4/5)^3$", and in the nineteenth line, "$(5/6)^2$" should read "$(5/6^4)$". The present paper contains a mass of data, statistically treated, resulting from crosses between the three sub-species, *leucocephalus*, *albifrons*, and *polionotus*, and also from a fortunate cross between two species of *Peromyscus*. The results are too numerous to summarise here, but the paper is a searching inquiry into the conception of multiple genetic factors as applied to sub-specific crosses. Differences in depth and extent of pigmentation, the tail stripe, and other features are believed each to depend upon several multiple factors, but it is concluded that the formulæ of Castle and Wright for determining the number of such factors is not applicable. The tables of measurements of tail, foot, ear, etc., in the hybrids have also been analysed. Wide phenotypic variability and other conditions offer great difficulties, and it cannot be said that the multiple factor hypothesis as here applied is a great success, in spite of the great care and attention to detail which has entered into the analysis. The author is inclined to favour the view that the genetic changes between sub-species have resulted in some direct way from the action of the environment, the colour mutations being selectively controlled by their value in concealment.

Mitogenetic Rays.—A monograph upon this subject was reviewed in NATURE of July 13, 1929. It will be remembered that Gurvitsch and his school suggest that a special type of short wave length radiation promotes cell division; they thought to detect this radiation by pointing one growing root tip at another at close range, when the number of cell divisions in the second root was said to be greater, as the result of 'irradiation' from the tip of the first root, on the side 'exposed' to the pointing tip. Around this conception a lively controversy has raged, and so long as the only tests applicable to mitogenetic radiation are the number of cells in a tissue in a state of division, or the number of buds produced in a growing yeast culture, conclusive critical evidence in support of the new radiation remains difficult to produce. Of considerable importance therefore is a paper by Stempell (*Biol. Zentralblatt*, **49**, Heft 10; 1929) in which he attributes to the radiant energy from such growing organs the power of destroying the Liesegang rings which are formed with beautiful regularity when a drop of silver salt is placed on the centre of a thin layer of gelatin containing ammonium bichromate. These experiments of Stempell have been repeated and confirmed by B. P. Tokin (*Biol. Zentralblatt*, **50**, Heft 11; 1930), but at the same time this worker makes it clear that this interesting result is due to the volatile substances, probably ethereal oils, which are given off from the crushed tissue of the onion, which has been the source of the 'mitogenetic' radiation in these experiments. Tokin's work seems to make it quite clear that this new experimental field has failed to produce any evidence for the existence of 'mitogenetic rays'.

Mica-Peridotites of India.—In his memoir on "The Jharia Coal Field" (*Geol. Surv. India*, vol. 56; 1930) C. S. Fox gives a valuable account of the remarkable peridotite intrusions associated with the faults and coal seams of the region. The coalfields of the Damuda valley represent a series of areas of Gondwana sediments set in a pavement of Archæan gneisses on which they lie and into which they have been faulted. The synclinal structures of the so-called basins result from tectonic movements. The peridotites are generally much altered. Many are characterised by an abundance of mica, but the most remarkable feature is the richness in apatite, as first disclosed by Sir Thomas Holland in 1894. The high phosphorus content in the coals of many of the Gondwana fields can be traced with tolerable certainty to the peridotite intrusions. A number of new analyses are presented and attention is directed to these because of their petrological and geochemical significance and because they might easily be overlooked in a memoir dealing mainly with coal. The peridotite magma appears to have been squeezed up through fault planes in the gneissic floor, but once it entered sedimentary rocks the bedding planes offered numerous channels for escape, mainly above or below coal seams, where the bedding planes appear to have been more easily separable than elsewhere in the series.

Comparative Study of Soil Profiles.—An exceptionally thorough investigation of soil profiles in Holland and Java has been made by A. Te Wechel, L. Möser, and C. Van Aggelen (*Mitt. Geol. Inst. Landbouwhoogeschool in Wageningen, Holland*, No. 16, 1930). The profile on Senonian limestone in Holland is compared with the profiles on loess in Holland and on Tertiary limestone in Java. The end products of soil formation are closely similar from the two contrasted types of parent rock in Holland, whereas they are widely different from the two similar rocks studied in Holland and Java (see table). The importance of climatic control is thus clearly demonstrated. The microscopic (petrological), physical, and chemical character of the parent rocks and of four or five horizons in the profiles of each of the three examples investigated have been very fully determined. The memoir is well illustrated and constitutes one of the most illuminating studies of weathering and soil genesis yet issued.

Constituents	Holland		Java
	Loess Soil	Limestone Soils	
$CaCO_3$	2.21	1.75	2.02
SiO_2	73.55	73.38	37.87
Al_2O_3	8.04	7.59	24.08
Fe_2O_3	2.89	2.63	8.95
Clay	41.40	40.50	37.80
Humus	5.14	4.42	4.31

The Constant of Gravitation.—A redetermination of the constant of gravitation (G), by P. R. Heyl, is described in the December number of the *Bureau of Standards Journal of Research*. The apparatus used was much the same as in the dynamical method of Braun, with, however, a considerable increase in the magnitude of the large attracting masses, and with the incorporation of the refinements possible to any one working in a large institution. The attracting masses on the moving system were small spheres of gold, platinum, and optical glass, in each case of about 50 gm., but with the large stationary masses a radical change in shape was made, cylinders being substituted for the spherical form which had been previously almost universally employed; the mass of each was about 66 kgm. The reduction of the experimental data is thus enormously complicated, but it has been found that series which remained manageable could still be calculated fairly readily to express the forces due to the cylindrical masses; full details of these, which are probably of value in other connexions, are given. Other points in the experimental arrangements are the use of tungsten filament wires for the suspensions in place of quartz, with very satisfactory results, and the magnetic shielding

of the small paramagnetic and diamagnetic spheres which was found to be called for The value finally adopted for the constant is $6\ 670 \times 10^{-8}$ cm^{3} gm^{-1} sec^{-2}, with a precision of 0 005, as measured by the average departure from the mean This result is in very good agreement with Boys' and Braun's value of $6\ 66 \pm 0\ 01$, in the same units There is a curious outstanding discrepancy in the apparent dependence of the value on the material of the small masses, but it is considered that this is not due to the nature of the material

Properties of Molecular Hydrogen—In a paper in the January issue of the *Proceedings of the Royal Society*, on the chemical constant of hydrogen vapour and the entropy of crystalline hydrogen, T E Stern has extended some earlier calculations made by R H Fowler, essentially by introduction of the Einstein Bose statistics in place of classical statistics His results are important chiefly from the fact that they increase somewhat the accuracy of results predicted by Mr Fowler, excellent agreement being obtained with Eucken's empirical values for the chemical constant In addition, however, Mr Stern has made some interesting remarks upon the nature of molecular motion in crystals His analysis, like that of Mr Fowler, assumes that the molecules of hydrogen rotate in the crystalline solid much as they do in the gas, and, as he points out, the reasonable nature of the predicted results furnishes good evidence for the validity of the assumption It is not certain, all the same, that the moment of inertia remains unaffected by passage to the condensed phase, and an experiment is suggested by means of which any such change could be detected There is possibly already evidence for a small diminution of the moment of inertia in formation of the liquid when liquid hydrogen is formed from the vapour from Prof McLennan's investigation of the Raman effect Rotation of molecules in crystals would appear not to be a universal phenomenon, as Mr Stern refers to a theoretical investigation by Pauling as showing that in some crystals molecules cannot rotate at all, whilst in others they move in an irregular fashion which corresponds to wave functions intermediate between those for pure rotation and for pure oscillation

Constitution of Coal—Two of the methods for studying the constitution of coal are the use of solvents for fractional extraction and the examination of the products of oxidation At a meeting of the Royal Society of Arts on Nov 26, Prof W A Bone summarised the results of his experience with these two methods (*Jour Roy Soc Arts*, **79**, 77) By means of benzene under pressure, material can be extracted from coals which is divisible into four fractions Prof Bone has adduced from this evidence that the solid fraction is really the material which imparts to a coal the property of forming a coke By controlled oxidation of the extracted residue he has not only confirmed the view that the main product is a mixture of benzene carboxylic acids, but also accounted quantitatively for the material of the reaction The same sort of product was obtained from coal in all stages of formation and in the carbonisation products, indicating that the benzenoid structure is present throughout He advanced the view that coal is of the nature of a 'bakelite'

Energy Distribution in an Oil Circuit-Breaker—One of the most difficult problems which electrical engineers have to solve is to devise switches capable of breaking circuits in which large currents at high voltages are circulating If the switch is incorrectly designed, the limit of rupturing capacity is low, and if used for large currents a short circuit results and the switch is destroyed Automatic oil switches are now in general use, as they have been found both efficient and trustworthy An arc drawn out between the separating contacts underneath the oil is rapidly cooled and compressed by the surrounding oil The special feature of the switch seems to depend on the squeezing effect of the oil on the arc In a paper read to the Institution of Electrical Engineers on Jan 8 by C E R Bruce, an elaborate study is made of the distribution of energy in an oil circuit breaker The paper is the latest of the reports on the subject made by the British Electrical and Allied Industries Research Association It deals in considerable detail with the energy dissipated by large oil circuit breakers at a pressure of 5500 volts Rough but satisfactory measurements have been made of the various ways in which the energy liberated is dissipated The energy dissipated at the contact surfaces and radiated from the arc was measured experimentally That required to heat, vaporise, and break up the oil was calculated The rest of the energy used for raising the arc to the gas temperature and in dissociating the hydrogen present could then be found and the temperature of the arc calculated The temperature found in this way was about 3500° K (3227° C) This value is nearly double the value (1750° C) which has previously been used Tests were made with both open and closed tanks and with copper and aluminium electrodes Interesting theoretical calculations are also given

Electric Incubators—In his recent address to the Scottish Centre of the Institution of Electrical Engineers, E Seddon gave an example of how electrical power is enabling the struggling industry of poultry farming to compete with imported products It is a good illustration of the gradual mechanisation of farming The Buttercup Dairy Co has an electrical poultry farm near Edinburgh stocked with 200,000 laying hens There have been installed nine incubators, each capable of holding 16,000 eggs The eggs are placed end downwards in special trays and packed tightly to prevent movement The trays are then placed in the incubators at an angle of 45° The eggs require to be turned during the process of incubation, by an ingenious device the trays are turned about a horizontal axis until they are perpendicular to their former position The motion is reversed every six hours Each incubator has an electric heater taking 2400 watts, which maintains the temperature between the limits of 99 5° and 100 F The heat is controlled thermostatically and if the temperature varies by so much as 1° a bell rings On the eighteenth day the trays of eggs are tested by being placed over high candle power lamps The unfertile eggs are quickly removed and the trays placed in the hatching compartments The chicks hatch regularly on the twenty first day The average number of infertile eggs is 21 per cent, and 9 per cent contain dead germs The chicks pass from the incubator rooms in cardboard boxes to the brooding rooms The essential requirements are a constant supply of fresh air, protection from draughts, uniform temperature, and a moist atmosphere Air drawn in by electric fans is steam warmed and then drawn upwards through the cages containing the chicks to the exhaust fan in the roof A complete change of air is effected every five minutes All windows are of blue glass and the electric lamps are tinted blue It is found that the chickens thrive under these conditions Special lighting is arranged in the laying sheds to ensure egg laying in the winter months Electrically driven conveyors convey the food to the bins, the consumption being about 150 tons of meal per week

Cleveland Meeting of the American Association for the Advancement of Science.

THE American Association for the Advancement of Science and its affiliated societies held their annual meeting at Cleveland, Ohio, during the week of Monday, Dec 29, 1930, to Saturday, Jan 3, 1931 The attendance shown by the registration records was 2635 The sessions were held in the lecture rooms of Western Reserve University and the Case School of Applied Science, the large gymnasium of the University was used as a registration hall and for the exhibits

The meeting was held under the presidency of Dr Thomas Hunt Morgan, of the California Institute of Technology The retiring president, Dr Robert Andrews Millikan, of the same institution delivered the principal address on Monday evening, on atomic disintegration and synthesis, this address appears in NATURE of Jan 31, p 167

At its meeting on Thursday, the Council, the governing body of the Association elected as president for 1931 Prof Frans Boaz, of Columbia University, long a leading figure in American anthropology The resignation of Prof Burton E Livingston, of the Johns Hopkins University, who has been permanent secretary of the Association for the past ten years, was accepted and Prof Charles F Roos, of Cornell University, was elected to fill the vacancy Prof Roos had been secretary of Section K (Social and Economic Sciences) since 1928 Prof Livingston was elected general secretary in succession to Prof Frank R Lillie of the University of Chicago

Sectional vice presidents for 1931 were elected as follows A (Mathematics), Dr Earl R Hedrick, University of California at Los Angeles, B (Physics), Prof Bergen Davis Columbia University, C (Chemistry), Dr Charles A Browne, U S Bureau of Standards, D (Astronomy), Dr J H Moore Lick Observatory, E (Geology and Geography), Prof Douglas Johnson, Columbia University, F (Zoology), Prof R W Hegner, the Johns Hopkins University, G (Botany), Prof Elmer D Merrill, New York Botanical Garden H (Anthropology), Prof W K Gregory, American Museum of Natural History, I (Psychology) Prof H S Langfeld, Princeton University, K (Social and Economic Sciences), Prof G C Evans, Rice Institute, L (Historical and Philological Sciences), Prof W B Munro, California Institute of Technology, M (Engineering) Prof Dexter S Kimball Cornell University, N (Medical Sciences), Prof H T Karsner, Western Reserve University, O (Agriculture), Dr C W Williams, Ohio State Agricultural Experiment Station, Q (Education), Prof Ernest Horn, University of Iowa

Plans were made for future meetings of the Association The present year will see the inauguration of the new plan for holding a meeting during the summer months, in addition to the winter meeting The first of the summer meetings will be held in Pasadena, California, in June The 1931 winter meeting will be held in New Orleans, Louisiana The summer meeting for 1932 will be held in New Haven, Connecticut, and the winter meeting probably in Atlantic City, New Jersey The summer meeting for 1933 will be held in Chicago The 1932 winter meeting should have been planned for Chicago, according to the policy of holding quadrennial meetings of the Association in Chicago, Washington, and New York in rotation, but the plan was modified to permit the Association to meet in Chicago while the forthcoming World's Fair there is in progress

The Association's prize of one thousand dollars for an outstanding paper presented at its winter meeting, given each year by an anonymous benefactor, was awarded for a paper entitled "Experiments with High voltage Tubes", presented by Dr M A Tuve, Dr L R Hafstad, and Odd Dahl, of the Carnegie Institution of Washington, Department of Terrestrial Magnetism Using a Tesla coil with a tuned spark in the primary, they have built up voltages of five million and above They have also constructed vacuum tubes of pyrex upon which a voltage of two million can be impressed without rupturing them Operating these tubes at a working voltage of 1 4 millions, they have obtained beta particles with a velocity within 1 per cent of the speed of light, and gamma rays of a corresponding intensity Since it is possible to achieve theoretically unlimited voltages by building up a large enough series of Faraday cages, sufficiently well insulated, Dr Tuve and his associates intend to carry their researches with high velocity discharges just as far as the limits of available materials will let them

Another paper of outstanding interest and of great potential practical significance, though it was not entered for the consideration of the prize committee, was that of Dr W W Swingle, of Princeton University, and J J Pfiffner, of Coldspring Harbor, N Y, on "The Hormone of the Suprarenal Cortex" The authors have used a cortical extract successfully in reviving animals prostrate and apparently at the point of death from adrenalectomy It has also been employed successfully in the clinical treatment of Addison's disease, hitherto regarded as incurable A number of other papers were presented on endocrine physiology, especially on the effects of various hormones on the physiology of reproduction

Dr Harlow Shapley, director of the Harvard College Observatory, announced that the compilation of the latest results of the sky mapping campaign of his observatory indicates an irregular distribution of galaxies in space The Harvard College Observatory now has photographs of about one tenth of the sky, showing all objects within the limits of photographic visibility These show hitherto unknown galaxies to the number of about eighteen thousand This irregular distribution of galactic matter in space, Dr Shapley said, favours the concept of a non static universe put forth by Le Maitre, Tolman, and others, as against the Einsteinian idea of a static universe, which demands a uniform distribution of galaxies

The planet Pluto, the discovery of which in 1930 was the outstanding astronomical event of more than a generation, was sought and found but left unrecognised eleven years ago Dr Seth B Nicholson, of the Mt Wilson Observatory, California, made this known for the first time in a paper read before the Section of Astronomy In 1919 workers at this observatory conducted a search in the region where the trans Neptunian planet had been predicted by Lowell The image of the planet appears on a number of their plates, but at the time it went unnoticed among the host of low magnitude star images After the discovery of Pluto by Clyde Tombaugh at the Lowell Observatory, Arizona, the old plates were checked over and the planet images found

A suggestion as to the possible mode of formation of petroleum in the earth was offered by Dr S C Lind, director of the School of Chemistry of the University of Minnesota Dr Lind and his associates have succeeded in synthesising carbon compounds of a complexity approaching that of the constituents of petroleum by subjecting simple compounds like methane to pressure, high temperature, alpha particle bombardment, and electrical discharges He suggested that pressures and energy discharges developed in the process of crustal movements, acting

on simpler hydrocarbons, might readily have built up the larger molecules of petroleum He would not at the present time, however, undertake to say whence came the simpler hydrocarbons, the raw materials in this geokinetic manufactory

A lipoid extract from tuberculosis bacilli was reported to act as a true antigen against the organisms that produced it, by Prof R J Anderson, of Yale University Prof Anderson has also discovered a new fatty acid in the bacillus, which seems to be the active agent in the formation of the tubercles that are the name-symptom of the disease The new compound has been named phtiotic acid

A modification of the now classic Chamberlain Moulton hypothesis of planetary formation was put forward by Prof Kirtley Mather, of Harvard University Prof Mather accepts the idea that the nucleus of a planet is provided by the tidal extrusion of a ' bolt ' of stellar stuff, caused by the near approach of two stars He believes that this initial bolt contains the larger part of the mass of the new planet, possibly nine tenths of it, including nearly all of the heavy metals, especially iron and nickel Planetesimal accretions account for only the outer tenth of the total final spheroid

Of the numerous symposia, perhaps the most popularly attractive was that on the future of man, conducted by the American Society of Naturalists on the afternoon of New Year's Day This was participated in by Dr A V Kidder, of the Carnegie Institution of Washington, who presented the subject from the archæologist's point of view, Prof William F Ogburn, of the University of Chicago, who considered it from the sociological angle, and Prof E M East, of Harvard University, who spoke as a geneticist Prof Kidder opened the discussion in the rôle of a Cassandra, giving warning that if we are to build on the analogies furnished by past cultures, our own civilisation is in for a terrific crash unless by concerted action we head it off But beneath the shadow of this Spenglerian doom, the succeeding two speakers indulged in a fine bout of Wellsian prophecy They envisioned a world population of about three and one half hundreds of millions of people, speaking one general language, composed of blendings of all the races, though nationalisms, and probably wars, will continue Africa and the two Americas will be predominantly white, the native races will be largely extinguished, and their remnants absorbed into the dominating population The Malayan peoples will about hold their own, but will not increase their territorial holdings, the Mongolian race will expand greatly Birth control knowledge will be universal, parenthood, restricted by social pressure and indirect rather than direct legislation, will be honoured, and babies at a premium The stream of scientific discovery and invention will continue in ever increasing tempo, changing the social order faster than the social order can adjust itself to the changes, thereby keeping social sanctions and moral codes in a constant state of flux With oil all gone, coal supplies dwindling, and such natural sources as water and wind power insufficient, the world will be hard put to it for sources of power, for the ' cracking of the atom ' is a vain dream Many factories will go to the land for both raw stuffs and labour, instead of sending to the land for materials to be worked up in town Thus the entire population will be urbanised

Among the scientific exhibits, the one that attracted most attention was that of Dr George W Crile, a surgeon of Cleveland, who with his associates has re combined lipoid, protein, and mineral salt fractions of animal tissue, obtaining microscopic bits of colloid stuff which he calls ' autosynthetic cells ' Although they are not alive, they display many of the physicochemical phenomena of living cells, such as an electrical gradient from the centre outwards, absorption of food material (protein), increase in size, division into new units, absorption of oxygen and elimination of carbon dioxide, and deterioration and ' death ' in the presence of toxins

Of more immediate practical importance is the new X ray technique employed by Dr Thomas O Menees, of the Blodgett Memorial Hospital, Grand Rapids, Michigan, to learn the sex of a fœtus so much as three months before birth The method consists in the injection into the fœtal circulation of a small quantity of strontium iodide This is non toxic, and opaque to X rays, thus permitting the photography of fleshy parts as well as bone The effect fades after three hours and entirely disappears in a day It is expected that the new technique will be of value in doubtful cases where a Cæsarian section seems to be indicated

The United States Bureau of Standards exhibited specimens of rubber vulcanised by a new method, employing trinitrobenzene instead of sulphur This rubber has the virtue of being non corrosive to metals that cannot stand contact with sulphur vulcanised rubber, making possible such things as rubber plated steel and copper Another exhibit of the Bureau of Standards was a set of ' fourth dimensional ' models constructed by Dr Paul R Heyl These bear the same relation to figures in the fourth dimension that the two dimensional pictures in books and on blackboards bear to figures in three dimensions

Dr Dmitry Borodin, who is working at the Boyce Thompson Institute, Yonkers N Y, presented a demonstration of his method for measuring the effects of mitogenetic radiation He cultivates yeast in hanging drop colonies, and measures with the planimeter the comparative areas of colonies exposed to the radiations and of control colonies

Though not shown in the exhibits, a new type of phonograph was mentioned in one of the discussions of the physics section This uses, instead of records, motion picture film with twelve sound tracks on it The machine can use a five hundred foot film, and can play a two and one half hour grand opera at one ' loading ', The quality of the sound reproduction is said to compare favourably with high grade radio reception from a near by station Commercial production of the new film phonograph, however, is not planned for the near future FRANK THONE

Botany in South Africa

ON Nov 10, Dr Arthur W Hill, who has since had the honour of K C M G conferred upon him, landed in Cape Town, on the invitation of the Government of the Union of South Africa, for the purpose of making personal contact with botanical affairs in the country After spending some ten days in Cape Town, Sir Arthur Hill proceeded by the "Garden Route" to the forests of George and Knysna, proceeding from there to Port Elizabeth, Grahamstown, and East London, and then travelling to Bloemfontein and Fauresmith At the latter place Sir Arthur saw the work which is being carried out at the recently established Karroo Pasture Station He described this station as the most remarkable which he had seen in the course of his travels throughout the world. Here the semi-desert shrubs which form the vegetation covering the great Karroo areas were being investigated as regards their palatability, carrying capacity,

and food value From Fauresmith Sir Arthur Hill proceeded eastwards over the Drakensberg Range via Van Reenen's Pass and Ladysmith to Pietermaritzburg, from which place he travelled to Durban From Durban he went to Pretoria and, after spending ten days there, travelled north to the Woodbush Mountains and thus completed his tour in the Union

Before Sir Arthur left Pretoria, the Union Government gave a reception in his honour at the botanical laboratories attached to the Division of Plant Industry At this reception Col G N Williams, Secretary for Agriculture, welcomed him on behalf of the Union Government In doing so, he spoke of the long and close association which Kew had had with the South African Departments of Agriculture, and also mentioned the many botanical expeditions with which Sir Arthur had been connected in different parts of the world

Mr C E Legat Chief Conservator of Forests, welcomed Sir Arthur on behalf of the Forest Department He mentioned the assistance which the Department of Forests had received from Kew, and stressed the fact that South Africa had to depend upon the introduction of exotic trees because the native timbers took between 150 and 200 years to mature

Dr I B Pole Evans Chief of the Division of Plant Industry and Director of the Botanical Survey of South Africa, welcomed Sir Arthur on behalf of the botanists of South Africa He described the great benefits which Kew had rendered to South Africa, and referred to the publication of the "Flora Capensis" and the assistance which the South African Governments had given in the matter He referred to the close association between the Botanical Survey of South Africa and Kew, whereby the Survey had maintained at Kew for some years past a South African botanist to assist with critical determinations, etc Dr Pole Evans mentioned the botanical areas, institutions and problems which Sir Arthur had seen, and expressed the hope that he would realise that botanical science had made considerable strides in the country during the past twenty five years, and that South Africa must in the future endeavour to help herself much more than she had in the past

Sir Arthur in returning thanks to the Government for its invitation, referred to the great importance and educational value of botanic gardens He stated that he would like to see three great botanical gardens flourishing in the Union There were the Kirstenbosch Gardens, but in addition he would like to see one in Natal and one in Pretoria He spoke of the excellent work which was being done at Fauresmith and at Pretoria on the pasture plants of the country, and also stressed the importance of the work that was being done by the Botanical Survey Regarding forestry matters, Sir Arthur expressed high appreciation of the work for the preservation of native forests in the Knysna area In concluding, he hoped that means would be found for subsidising post graduate research work in botany, since he thought South Africa would derive considerable benefit from work of this nature

General Smuts moved a vote of thanks to Sir Arthur Hill, the British Government, and the Union Government, and pointed out that Sir Arthur was the first of Kew's great directors to undertake a tour of the Dominions—and in this connexion General Smuts paid a great tribute to the foresight of the Empire Marketing Board in making this possible He referred to the valuable gift which Sir Arthur had made, through Kew, to the National Herbarium at Pretoria by donating type specimens of many of the older collections, and pointed out that the National Herbarium at Pretoria would now be able to do a very large part of the work which Kew originally did He expressed the view that the time would probably come when South Africa might well become one of the great pasture countries of the world, and for this reason, every effort should be made to develop the country's natural resources This might in time become a question for the whole of Africa, and they would see not only one institution, not only one country such as the Union, but all the African Governments collaborating and trying to solve common problems Science would have to be applied more and more to the economic situation General Smuts referred to the great spaces in South Africa and the difficulties which isolated workers had to contend with, and he felt that Sir Arthur's visit would be a great inspiration to those people

After the speeches of welcome, Dr A C Leemann spoke on "Plant Immunity and the Aims of Modern Plant Pathology" He gave his audience the benefit of his researches in his own entirely new line of work in the realm of plant immunity, in which, by reinforcing soil conditions he has found it possible to effect a marked change in the immunity of plants to certain fungus diseases Dr Leemann supplemented his remarks by giving a demonstration of plants which had been inoculated under these conditions

Guests were then given the opportunity of inspecting a very interesting and instructive series of exhibits illustrating the work of the Division of Plant Industry These included amongst others —(1) Photographs of much of the vegetation of those parts of the country which Sir Arthur Hill had not been able to visit (2) A collection of old type specimens presented to the National Herbarium by Kew and Berlin (3) A collection of living pasture grasses recently collected on a tour from Pretoria to Lake Tanganyika (4) A trap specially designed by Mr H Harris, as a result of his work in Zululand, for catching tsetse flies The success already achieved by the use of this trap opens up considerable possibilities with regard to tsetse fly control (NATURE, Nov 22, p 817)

This visit of Sir Arthur Hill to the Union of South Africa is of outstanding significance, and much of botanical interest should accrue from it, for there is probably no part of the British Empire which has contributed more towards the pure and economic branches of botanical science, and it is scarcely possible to encounter a flora which could excel that of South Africa in beauty and scientific interest

Scotland's Testimony to the March of Evolution.

THIS subject formed the main part of Prof James Ritchie's inaugural address (reprinted in part in the *Scottish Naturalist*, Nov Dec 1930) on his induction to the Regius chair of natural history in the University of Aberdeen

Prof Ritchie reminded his audience that bears were once common in the Caledonian forest, and that he, with his collaborators, had found in caves near Inchnadamph, in Sutherland, bones of bears, remains of wolves, lynxes, Arctic foxes, and lemmings, and more than nine hundred antlers of reindeer All these animals, and more besides, have disappeared from Scotland, they have been swamped in the struggle for existence Red deer, once common throughout Scotland, are now restricted to the Highlands, wild cats, pine martens, and polecats are dying out, and the white tailed eagle, the kite, and the osprey have disappeared On the other hand, many species of wild ducks are now nesting where they never bred before, and the fulmar petrel, for centuries confined

to St Kilda and its islands, has in a generation colonised the north coast and the east coast to Flamborough Head. These and other changes in the balance of life illustrate the accommodation of living things to changing conditions and hence successful colonisation, and, on the other hand, the failure to accommodate and consequent elimination

In his second line of evidence, Prof Ritchie referred to examples of the plasticity of living forms "Put broadly, Creationism emphasises the immobility of living forms, Evolution emphasises their plasticity" He pointed out that in a relatively short time Scotland has impressed its mark upon domestic animals among horses it has bred the Clydesdale, among cattle Aberdeen Angus, Ayrshires, Galloways and Kyloes, among dogs Skye terriers and others, among sheep Cheviots and Highland blackfaces—surely sufficient evidence of the plasticity of living forms that evolution demands Granted that this plasticity can be made apparent by man's efforts, what evidence is there that it plays a part in natural processes? Prof Ritchie believes that Scotland demonstrates better than almost any other country the evolution of life in progress The former fauna was entirely obliterated in the ice age, and the new fauna flocked into the country from Europe But all the animals are not exactly as they were, changes have been taking place revealed by the intense examination of modern zoologists The red grouse of Scotland is clearly different from the willow grouse of the Continent, it is a different species Of the one hundred and fifty-nine different species of birds which breed in Scotland, thirty two show characters which distinguish them from their closest relatives on the Continent Others—and thirty one of these are named—are distinct geographical races which, although differing from their continental relatives, are not different enough to be regarded as distinct species Of the fifty six different species and races of mammals which breed in Scotland, thirty are different from the most closely related continental forms, and of these, specialists have regarded eight as distinct species and twenty two as geographical races

Prof Ritchie illustrated his argument by particular reference to the St Kilda house mouse and the St Kilda field mouse, both regarded as distinct species, and remarked that it is reasonable to suppose that these are the direct descendants, slightly modified, of the original migrants from the common fauna of Europe

"In the fauna of St Kilda and in the thirty two distinctive birds and thirty distinctive mammals of Scotland we are looking upon the modelling from old species of new species and of geographical races, which we regard as the incipient stages of new species

"In the changes taking place in the balance of life, in the plasticity of animal form, and in the formation of new races and species not in the distant past of geologists, but in recent times, we are looking in Scotland upon evolution in its course"

The Mechanics of Mountains *

THE earth's upper crust in the continents appears from seismology to consist of three layers, an upper one of granitic constitution, about 10 km thick, an intermediate one about 20 km thick, the properties of which fit tachylyte, and a lower one probably of dunite, extending half way to the centre of the earth Above the granitic layer is the sedimentary layer, with an average thickness of probably about 2 km, but considerably thicker in special regions The outflow or inflow involved in maintaining isostatic compensation is in the lower layer, but at a smaller depth than 50 km

The mechanical properties of the outer crust indicate that the crustal shortening in a major epoch of mountain formation should be of the order of 40 km The actual height and extent of the great ranges correspond to a shortening of about 60 km This estimate is arrived at by considering what elevation would be produced if the light upper layers were compressed by a given fraction of their original length and enough outflow in the dense lower layer took place to restore isostasy

This estimate is much less than the horizontal movement observed in the field, and the only possible explanation is that the horizontal movement is a surface phenomenon almost confined to the sedimentary layer and caused by the crustal shortening, but not equivalent to it

Prolonged deposition of sediments leads to an obstruction of the normal outflow of heat from the earth, and hence to an increase of temperature and a reduction of strength through a depth of the order of 100 km, thereby localising the yield when the stresses due to contraction of the interior become too great for the strength of the outer crust to withstand The immediate result of a local failure would be a local elevation so high that the heated sediments would proceed, as a secondary effect to flow out horizontally under gravity and give a series of flat folds closely resembling the observed nappes Explanations of 'back folding' and of the gneissic core of a great mountain system appear to follow naturally

Emphasis is laid on the importance of recognising the intermediate layer in discussions of the mechanics of geological processes Isostatic readjustment can take place by horizontal outflow in this layer as in the lower layer, though much more slowly, and this process may play an important part in the formation of geosynclines and the levelling of old mountain systems

* Substance of a lecture by Dr H Jeffreys, F R S on The Mechanics of Mountains, at the Geological Society of London, on Dec 31, 1930

Sinkage of Logs

THE sinkage of logs during the river journey to the pulp wood mills is a matter of considerable importance owing to the loss thereby incurred The question has formed the subject of research by Prof G W Scarth, Botanical Department, McGill University, and Mr E C Jahn, associate professor of chemistry, School of Forestry, University of Idaho, the work being assisted by funds contributed by the Canadian Pulp and Paper Association A paper on "Sinkage Studies—I" has now been published (*Can Jour Research*, vol 2, June 1930) Experiments were made with logs of jack pine, spruce, poplar, balsam, and birch

The distribution of water in floating logs (in a lake) was found to be similar to that in living trees It was noted that the sapwood of these species became wet all round whilst the heartwood was relatively dry, becoming wetter in the order of the species given above, the heartwood in birch became as wet as the sapwood The rate of radial penetration of water into logs of these species increased in the order, birch, jack pine, spruce, balsam, poplar, the penetration

taking place very slowly, even into the sapwood Narrow outer rays and density of the wood diminish the rate of penetration The advantage of a large proportion of relatively dry heartwood depends more on the initial buoyancy it confers than on the greater resistance to penetration it may possess In air dry logs penetration of free water is also very slow, saturation of the cell walls precedes it at a greater rate The gas in floating logs is surrounded by water and can only escape in solution There appears to be evidence that more gas may be liberated by fermentation of storage material in the parenchyma cells

The problem as to whether escape of gas or penetration of water is the leading factor in determining the rate of sinkage of cut logs has been studied by Mr R D Gibbs, of the Department of Botany, McGill University and published under the title "Sinkage Studies—II" (*Can Jour Research*, June 1930) The species investigated were balsam, jack pine, birch, and poplar In freshly cut softwoods, possibly excepting balsam, the water content is fairly uniform, very high in the sapwood but low in the heartwood In birch the water content was higher in the centre than near the outside whilst the reverse was the case in poplar In jack pine the heartwood contained about 12 per cent water, the sapwood 52 per cent Generally the heartwood contains more gas than the sapwood, and consequently the greater the proportion of heartwood in a log the better its floating properties In the jack pine the heartwood contains 60 per cent of gas and the outer layers of wood about 23 per cent Wood and density values vary considerably Consequently, even by allowing for the variation of density across a log the errors in measurement are scarcely reduced In order to reduce error, standardised lots of logs should be examined, and seasonal and other measurements should be restricted to these lots

The results of this investigation, when it has been carried further are likely to have a wider application than to Canada alone, and they must therefore be regarded as of high value

University and Educational Intelligence

Cambridge —It has been announced by the vice chancellor that the treasurer has received a cheque for 5000 dollars "as a grant toward Dr Eric K Rideal's new department of colloids" No condition is attached to this gift, except that the donors do not wish their names to be published

Mr G U Yule of St John's College, has been appointed reader in statistics Miss M M O'Reilly, of Girton College has been appointed assistant curator of the Museum of Archæology and Ethnology

The vice chancellor has given notice that the Montague Burton professorship of industrial relations has been established, and that a meeting of the electors will be held on Feb 27 Candidates are requested to communicate with the vice chancellor on or before Feb 14

Sir Walter Thomas Layton has been elected to an honorary fellowship at Gonville and Caius College

Edinburgh —The University Court at its meeting on Monday, Jan 26, received, with much regret, intimation from Prof A Robinson, professor of anatomy, of his intention to retire at the end of the current academical year Dr C H O'Donoghue was appointed director of studies to students taking combined degrees in medicine and science Leave of absence for the summer term of 1931 was granted to Prof G Barger, in order to enable him to deliver a course of lectures in the University of Heidelberg It was announced that the Right Hon Winston Churchill would deliver the Rectorial Address on Thursday, Mar 5 Mr M Davidson was appointed lecturer in the Department of Engineering, to give a course of lectures and laboratory work in the subject of heat engines for second-year students The Court received, with gratification, intimation of the gift to the University Department of Geology, by Mrs Currie, of the valuable collection of minerals formed by the late Dr J Currie

Oxford —On Jan 27 a decree was passed by Congregation authorising a grant towards the expenses of a projected Oxford University Expedition to Baffin Island in the summer of 1931 This expedition will have similar objects to those of the recent expedition to Spitsbergen Another decree authorised the Curators of the University Chest to receive sums not exceeding £500 per annum for the purposes of a scheme of research in economic ornithology, the scheme to be carried out by the Department of Zoology and Comparative Anatomy

Notice is given by the Royal Society that applications for the government grant for scientific investigations must be made on special forms, returnable to the Clerk to the Government Grant Committee, Royal Society, Burlington House, London, W 1, by, at the latest, Mar 31

In 1926 a Commission was set up which inquired into and advised on the system of technical education in relation to the requirements of trade and industry in the Irish Free State It stressed the necessity for a sound organisation of continuation schools and classes, the object of which was to link the work of the primary school at age fourteen years with that of the technical school at age sixteen years, when young people normally enter employment The Vocational Education Act imposes upon newly appointed vocational education committees the duty of establishing and maintaining such continuation schools and classes A memorandum has been issued by the Department of Education with the view of assisting the committees in their task ("Vocational Continuation Schools and Classes in the Irish Free State" Messrs Eason and Son, Booksellers, Lower O'Connell Street, Dublin) Since out of approximately 120,000 young persons between fourteen and sixteen in the Free State, 45 000 are in primary and secondary schools, the task of the committees is to provide suitable education for the remaining 75,000 Although the memorandum is confined to the subject of continuation schools and classes, it specifically stresses the fact that it conveys no suggestion of diminished activity in technical education On the contrary, the anticipation is that provision of organised continuation classes will lead to an increased demand for technical education The memorandum is divided into two parts, the first of which recapitulates the relevant sections of the Vocational Education Act with which the committees must deal It indicates that obligatory attendance will not become operative until the necessary order is made careful and complete organisation is, however, the necessary preliminary to the making of that order In developing their schemes the committees are to secure information on the occupations open to young people in their area, the conditions of entry into these occupations, the forms of skill and knowledge helpful to beginners, and the attitude of employers, employees, and parents to vocational education By this means definite and reliable advice will always be available. Suggestions for organisation of rural education, the use of existing technical schools, and the gradual provision of new buildings are given The second part of the memorandum deals with the details of organisation and curricula

Birthdays and Research Centres.

Feb 8, 1868 —Lord ROTHSCHILD, F R S , Trustee of the British Museum

I have studied the morphology and systematics of birds and butterflies and moths for forty five years, and have endeavoured to make a world wide collection of these, as complete as possible, to serve as material for higher studies in structure, evolution, and geographical variation, for which larger series of each species and race are necessary than the usual museums can find space for

I am, at the present moment, much occupied in the study of certain melanic mutants of birds and insects, and it would be of great interest in the investigation of evolution if a careful study could be made of these melanic forms, in order to ascertain why melanic forms are almost invariably dominant, while white or blue forms are recessive Miss Edna M Turner is at present at Cambridge studying the question whether *physiological* and *chemical* differences are inheritable, and as melanic forms are due to an excess of *melanin* in the organism suspected, her line of investigation will be the one to demonstrate incidentally the reason for dominance or the opposite

Feb 11, 1862 —Dr F S MACAULAY, F R S , formerly mathematical master at St Paul s School London

A solution is desired of the following problem — Let f represent any polynomial in n variables, x_1, x_2 x_n with coefficients belonging to a corpus K, and ϕ any polynomial in x_1, x_2, x_r only, with coefficients in K Let M be a module of polynomials with a given basis $(f_1, f_2, \quad f_k)$, that is, let M be the whole aggregate of polynomials $a_1f_1 + a_2f_2 + \quad + a_kf_k$ where $f_1, f_2, \quad, f_k$ are given, and $a_1, a_2, \quad, a_k$ are arbitrary, polynomials of the type f It is required to find (that is, to devise processes for finding) a basis $(f_1 \; f_2, \quad f_k)$ of the module M which is the aggregate of *all* polynomials f such that $\phi' f' - 0(M)$, where f is an f and ϕ' a ϕ (n, r, k are given, but not λ)

A step towards the solution is to find at least one particular ϕ such that $\phi f = 0(M)$ for every $f = 0(M)$ Then M can be more simply described as the aggregate of all polynomials f' such that $\phi f' = 0(M)$, where ϕ is known One value for ϕ is $\phi_1' \phi_2 \quad \phi_k$, where $\phi_i \; f_i - 0(M)$, but this only shows that a ϕ exists satisfying the conditions

Feb 14, 1896 —Prof E A MILNE, F R S , Rouse Ball professor of mathematics in the University of Oxford

My chief investigation now in progress is on the structure of the stars, their interiors and atmospheres

Observational astrophysics is rapidly increasing in scope, accuracy, and richness of method, but theoretical astrophysics scarcely as yet bears the same relation to observational astrophysics that theoretical physics bears to experimental physics Theoretical astrophysics is largely an array of disconnected investigations of special points It needs to acquire classical theorems and a recognised logical development The beginnings of this are indeed to be found in the solutions of the classical problems associated with the names of Schuster, Schwarzschild, and Emden But at present it is as if theoretical physicists were devoting themselves to working out the consequences of each separate experiment instead of synthesising a theory of general principles Rather than investigating the detailed stellar situations disclosed by special observations, the worker in theoretical astrophysics might well devote himself to the more abstract aspects of idealised problems A sharp distinction needs to be drawn between the manufacture of theories about the stars and the investigation of idealised models The former need the touch of inspired imagination The latter can be tackled by all, have a permanent value independent of current theories, and afford a sound background and corrective to speculation Astrophysics might then emerge as a science as exact as geometry

Societies and Academies

LONDON

Mineralogical Society, Jan 13 F C Phillips On a soda margarite from the Postmasburg district, South Africa A fuller description is given of material first described by A L Hall The mineral occurs in mica like crystals associated with the Postmasburg manganese ores The physical properties described resemble in general those of a mica, but analyses show 50 per cent of alumina and 10 per cent of alkalis, with little lime It is best described as soda margarite, in composition it resembles the 'ephesite' of J L Smith —**F A Bannister** On the distinction of analcime from leucite in rocks by X ray methods Powder photographs of phenocrysts in blairmorite from the Lupata Gorge, Zambezi River, Portuguese East Africa, are identical with those for analcime and not for leucite The icositetrahedral outlines of the analcime phenocrysts found in the rock strongly suggest their primary origin The X ray photographs indicate that the phenocrysts are not single crystals, but consist of aggregates of particles in sub parallel position **F A Bannister** On a chemical, optical, and X ray study of nepheline and kaliophilite (with chemical analyses by M H Hey) correlated data have enabled the author to prove the approximate constancy of the number of oxygen atoms in the unit cells of several nepheline and elæolite specimens Thence the numbers of atoms of each kind per unit cell have been counted The cell volumes and optical properties have also been related to the chemical composition An approximate structure is suggested which, together with the chemical work explains the variable composition of nepheline Kaliophilite is shown to possess a much larger cell than that of nepheline, and its Lauegram exhibits higher symmetry Pseudonepheline (rich in potassium) has a slightly greater cell volume than normal nepheline, but its Lauegram is almost identical and its axial ratio the same —**H V Warren** On an occurrence of grunerite at Pierrefitte, Hautes Pyrénées, France A grunerite schist consisting almost entirely of fibrous grunerite, occurs at the Pierrefitte mine where needles of the same mineral also occur in the galena and blende of the ore bodies The grunerite is associated with a carbonaceous schist and with magnetite, and encloses specks of carbon Analyses of grunerite from schist and ore by E G Radley are given

Geological Society, Jan 14 —**E S Cobbold** Additional fossils from the Cambrian rocks of Comley (Shropshire) Species referred with reserve to *Micmacca* Matthew in 1910 are now confidently placed under that genus, or under *Strenuella*, and the relationships between *Protolenus*, *Strenuella*, and *Micmacca* are noted The very plentiful *Ptychoparia attleborensis* Shaler and Foerste is placed under Walcott's genus of the Eodiscidæ, *Pagetia*, on the strength of an enrolled specimen of the complete dorsal shield Some six or eight specimens of *Weymouthia nobilis* Ford throw considerable light on this species A new genus is proposed for an undescribed Lower Cambrian

trilobite, which seems intermediate between *Dorypyge* and *Centropleura*

Linnean Society, Jan 22 —**C G Trapnell** Vegetation in Godthaab Fjord West Greenland The Oxford University Greenland Expedition, 1928, worked principally at Iserssintilik, in Godthaab Fjord, lat 64° 40 N The problem of the classification of this heath is considered with reference to the climatic series of vegetation types found and to competition —**B P Pal** Burmese Charophyta An investigation into the systematics, distribution, ecology, and economic importance of Burmese Charophytes Burma has a large number of species belonging to the genera *Chara* and *Nitella* The importance of Charophyta as destructive agents of Culicid larvæ was negatived by experiments on *C gymnopitys* and two species of *Nitella* An apparent larvicidal effect in one case was discovered to be due to the presence of larvæ eating insects

BRUSSELS

Royal Academy of Belgium, July 5 —**Th De Donder** The invariantive theory of the calculus of variations (9) —**H Buttgenbach** Mineralogical notes Crystals of gold of sphene, and of garnet —**Oct Dony** The reduction of zinc oxide by carbon monoxide in a gas cycle, and on the mechanism of this reduction Carbon monoxide, formed by circulating carbon dioxide over graphite at about 1000° C, rapidly reduces zinc oxide at about 1040° C to metallic zinc The admixture of solid carbon with the zinc oxide is unnecessary —**Victor Willem** The architecture of bees —**L Godeaux** An algebraic variety representing couples of inverse points of space and on surfaces of the fourth order having four uniplanar double points —**Jean Genard** A new resonance series of sulphur vapour —**R H J Germay** The rôle of an exponential in the development in series of solutions of generalised Lagrangian equations The application to the Gauss equation —**G Gilta** The crystalline form of some alkylarsinic acids and alkaline alkylarsinates —**A Heyting** Intuitionist logic —**R Deladrière** Generalisation of the fundamental identities of the Einstein gravific

Aug 2 —**Victor Willem** The respiratory operations in *Xenopus* —**Th De Donder** Invariantive theory of the calculus of variations (10) —**Lucien Godeaux** The groups of three *W* congruences having a common focal surface **E De Wildemann** Aerial roots —**J Melon** Two minerals from the Belgian Congo a non pyroelectric tourmaline with special facies and a colourless chrysoberyl without twinning —**Marcel Winants** New applications of the theory of integral equations **Miron Nicolesco** Functions conjugated on a surface as defined by Beltrami —**R Bouillenne** Contribution to the study of the phenomenon of osmosis in plant cells A new apparatus for the measurement of the velocities of penetration of saline solutions in plant protoplasm —**R Bouillenne** Studies on the permeability of cells of *Tradescantia virginica* and of *Allium Cepa* Applications of the apparatus described in the preceding communication —**R and M Bouillenne** Sexuality and cellular oxidations in *Mercurialis annua* —**M and R Bouillenne** Experimental researches on the toxic agent of the pollen of Ambrosia An investigation into the chemical constitution of pollen poisons A bibliography relating to hay fever is appended —**Constant Lurquin** The functional relations for the mean elements of probability

ROME

Royal National Academy of the Lincei Communications received during the vacation, 1930 —**G Andreoli** Pseudo integrals and pseudo derivatives —**Maria Pastori** Partial derivation of tensors in relation to their intrinsic and partially intrinsic representation —**Vladimiro Bernstein** Ultra-convergence (*Ueberkonvergenz*) of certain Dirichlet series —**Radu Badesco** Singularities of the solutions of a class of integral equations —**M Manarini** Asymptotic lines on a surface Application of Levi Civita's conception of parallelism leads to the establishment of a necessary and sufficient condition for a line traced on a surface to be asymptotic —**M Pierucci** The orbit of the ultra Neptunian planet (2) With the new data for Lowell s planet obtained by Crommelin in July last, the three values for $\sqrt{ab}$ as yet found are 40 40 and 39 12 (Crommelin) and 39 90 (Banachiewicz) The mean of these values, 39 81, differs from the value calculated according to the author's rule by 0 46 per cent, and the mean difference between the calculated and observed equivalent radii is reduced to 4 31 per cent —**L Caldo** Julian reform of the calendar —**G Boaga** Formulæ for the topographic corrections in Eötvössian remainders —**A Belluigi** Physical characteristics of the Modenese Apennine marginal plain —**M Lombardini** The motion of the mass of air in the atmosphere —**C Dei** Determination of the vapour pressure of ice at low temperatures The method of measurement employed is based on the values of the explosive potential in a discharge tube corresponding with different known values of the density of the water vapour filling the tube The results thus obtained for the vapour pressure of ice, in mm of mercury, are at −22 3° 0 58 ± 0 023, at −55°, 0 0166 ± 0 0008, and at −66° 0 0037 ± 0 0002 These values agree satisfactorily with those given by other authors —**B Del Nunzio** A thermal analogue of the Barkhausen effect —**D Graffi** The theory of the propagation of heat by natural convection —**G Bozza** The mode of action of certain gas blowers (2) —**A Nasini and G Natta** The crystalline structure of the inert gases, krypton (2) X ray examination of solid krypton by the powder method in a special chamber reveals a face centred cubic structure The unit cell, which contains four atoms has a side of 5 78 A and the volume 193 × 10 ⁻²⁴ c c the density is 2 83 —**G A Barbieri** Colour reactions of the molybdo octocyanides —**C Sandonnini and S Bezzi** Catalytic decomposition of cetyl alcohol At 340° 350° and in presence of oxides of aluminium zinc, chromium, or iron, cetyl alcohol behaves similarly to primary alcohols with fewer carbon atoms Dehydration of the alcohol by means of alumina furnishes a simple method of preparing hexadecylene in good yield —**G R Levi and D Ghiron** Oxidation and reduction cells of alkali chlorites (2) —**A Ostrogovich and V Galea** γ Triazines Synthesis of two aralkylaminothioltriazines Benzylaminothioltriazine prepared by the method used for obtaining the corresponding alkyl derivatives, melts and decomposes at 270° 271° while styrylaminothioltriazine, obtained by the method used for the aryl compounds, melts and decomposes at 284° 285° —**C Richard** A peculiar asymmetry of *Physeteridae* and its relation to cranial asymmetry —**G Mezzadroli and E Vareton** Action of ultra short electromagnetic waves, λ = 2 3 metres on silkworms The action of an exposure of thirty minutes daily to these waves manifests itself in an acceleration of the life cycle After 20 days of the treatment, commencing when the worms are 15 days old, the increases in weight and length are respectively 112 and 37 per cent The irradiated worms begin spinning some days earlier and give an appreciably greater yield than the untreated controls —**G Brunelli** Colonisation of artificial lakes —**Giulio Cotronei and Celso Guareschi** Zoological constitution and transplanting Experiments on *Anura* and

Urodeles (5).—Aldo Spirito. Experiments on the grafting of more extensive embryonic parts between *Anura* and *Urodeles*.—C Jucci Cocoon colour and blood-pigment migration to the silk in the F_1 of reciprocal crosses between the Chinese gold, native yellow, and Japanese white races of silkworms.—M Mitolo Reflex excitability as a function of pH

WASHINGTON, D C

National Academy of Sciences (*Proc*, Vol 16, No 10, Oct 15).—Paul S Epstein Reflection of waves in an inhomogeneous absorbing medium A mathematical discussion It is concluded that for an angle of incidence larger or slightly smaller than the angle of total reflection, a non-conducting medium gives total or considerable reflection, a slightly conducting medium behaves similarly With increase of conductivity, reflection decreases rapidly and the coefficient of reflection becomes very small with large conductivity Hence reflection is insignificant except when conductivity is small and the conditions approach total reflection, thus in radiotelegraphy, if rays are reflected, their paths can be computed neglecting conductivity, as if the medium were transparent—G E Coghill The structural basis of the integration of behaviour Observations of the developing salamander indicate that the law or pattern of development consists in the expansion of a total pattern of action within which partial patterns arise by individuation through restriction of the field of motor action and the field of adequate stimulation This has been demonstrated for unconditioned reflexes and seems to apply to the formation of conditioned reflexes and instincts The structural basis of the law appears in the growth of the nervous system.—C Judson Herrick Localisation of function in the nervous system The first neuromuscular reactions in the salamander are executed by localised chains of neurons discharging into the total body musculature Innervation of limbs, etc, is an outgrowth from this integrated system Local reflexes are established, but the neurons in the brain conveying them are linked up in a dense network of fine nerve fibres (the 'neuropil') This diffuse and relatively equipotential neuropil provides the basis for behaviour generally, it is nearly homogeneous, but not quite, since every part receives a preponderance of fibres from specific sensory fields.—Wilder D Bancroft and George Bancroft Glycogen metabolism A reversible equilibrium, maintained by enzymes, between glycogen or glucose and lactic acid, is postulated Apparent displacement of equilibrium is due to changes in adsorption of glycogen by protein—Paul S Epstein Note on the nature of cosmic rays Rossi has suggested that if the cosmic rays are fast electrons, they have an energy a little less than 10^9 volts It is shown mathematically that electrons of 10^9 volts energy coming from outside would be much deflected by the earth's magnetic field and can strike the earth only in two limited zones around its magnetic poles Practically all countries where cosmic rays have been observed are outside these zones.—H T Engstrom Periodicity in sequences defined by linear recurrence relations

Diary of Societies

FRIDAY, FEBRUARY 6.

ROYAL SOCIETY OF MEDICINE (Otology Section), at 10.30 A.M.—Sir St. Clair Thomson, F C Ormerod, and others Discussion on Tuberculosis of the Ear

ROYAL ASTRONOMICAL SOCIETY (Geophysical Discussion), at 4 30.—The Escape of Radiation from the Atmosphere. Chairman, Sir Gilbert Walker Opener, Dr G C Simpson, followed by Sir Napier Shaw, Dr F J W Whipple, and Prof E A Milne.

EMPIRE SOCIETY, at 4 30.—J A Richey The Indian Educational System.

ROYAL SOCIETY OF MEDICINE (Laryngology Section), at 4 30.—Discussion on Frontal Sinusitis and its Treatment.

PHYSICAL SOCIETY (at Imperial College of Science and Technology), at 5.—H E. Beckett The Radiation Reflecting Powers of Rough Surfaces.—E B Moss A Ballistic Recorder for Small Electric Currents.—F J Scrase The Instrumental Phase Difference of Seismograph Records.

INSTITUTION OF MECHANICAL ENGINEERS, at 6.—H N Gresley High pressure Locomotives

COKE OVEN MANAGERS ASSOCIATION (Midland Section) (at Grand Hotel, Sheffield), at 6 30.—A. Grounds Some Aspects of Coal Treatment.

INSTITUTE OF TRANSPORT (Manchester, Liverpool, and District Section) (at Midland Hotel, Manchester) at 6 30.—C J H Trutch The Diesel Engine and the Railways.

SOCIETY OF CHEMICAL INDUSTRY (Manchester Section) (jointly with Manchester Section of Institution of the Rubber Industry) (at Engineers Club, Manchester), at 7.—A Fraser Plant Used in the Manufacture of Synthetic Resins.—Dr E E. Walker and E A Bevan The Effect of Certain Factors upon the Electrical Properties of Moulding Powder and Synthetic Resins.

INSTITUTION OF ELECTRICAL ENGINEERS (Meter and Instrument Section), at 7.—R. Davis G W Bowdler and W G Standring The Measurement of High Voltages, with special reference to the Measurement of Peak Voltages.—Dr L E Ryall The Construction and Operation of a Simple Neon Tube High Tension Crest Voltmeter.—S Whitehead and A. P Castellain Sphere Gap Calibration

INSTITUTION OF ELECTRICAL ENGINEERS (North Eastern Centre) (at Literary and Philosophical Society Newcastle upon Tyne), at 7.—Prof W Cramp The Birth of Electrical Engineering (Faraday Lecture).

OIL AND COLOUR CHEMISTS' ASSOCIATION (Manchester Section) (at Milton Hall, Manchester), at 7.—Members Evening

ROYAL PHOTOGRAPHIC SOCIETY OF GREAT BRITAIN (Pictorial Group), at 7.—Informal Meeting

JUNIOR INSTITUTION OF ENGINEERS (Informal Meeting), at 7 30.—J W White Aerial Wire Ropeways

INSTITUTE OF FUEL (Bristol Centre) (at Bristol University) at 7 30.—M H Lewis Recent Developments in Economy of Fuel for Small Boilers

GEOLOGISTS ASSOCIATION (in Botany Theatre University College) (Annual General Meeting), at 7 30.—Prof W W Watts Bournes (Presidential Address).

ROYAL SOCIETY OF MEDICINE (Anæsthetics Section), at 8 30.—A D Wright Spinal Analgesia, with special reference to Operations above the Diaphragm

ROYAL INSTITUTION OF GREAT BRITAIN, at 9.—J M Keynes The Internal Mechanics of the Trade Slump.

INSTITUTE OF BREWING (North of England Section) (Annual General Meeting) (at Midland Hotel Manchester).

SATURDAY FEBRUARY 7

ROYAL INSTITUTION OF GREAT BRITAIN, at 3.—Dr E Cammaerts Flemish Art (3) Rubens

MONDAY, FEBRUARY 9

ROYAL COLLEGE OF PHYSICIANS OF EDINBURGH, at 5.—Dr D K Henderson Social Psychiatry (Morison Lectures) (1)

INSTITUTION OF ELECTRICAL ENGINEERS (Informal Meeting), at 7.—R W L Phillips and others Discussion on Maintenance Service to Consumers in Rural Areas

INSTITUTION OF ELECTRICAL ENGINEERS (North Eastern Centre) (at Armstrong College, Newcastle upon Tyne), at 7.—P J Ryle Two Transmission Line Problems Suspension Insulators for Industrial Areas in Great Britain Conductor Vibration

INSTITUTE OF METALS (Scottish Section) (at 39 Elmbank Crescent, Glasgow), at 7 30.—D R. Tullis Gas Refinement of Metals and Alloys

ROYAL GEOGRAPHICAL SOCIETY, at 8 30.—Mrs. Patrick Ness To Lake Chad and the Sahara.

TUESDAY, FEBRUARY 10

ROYAL INSTITUTION OF GREAT BRITAIN, at 5 15.—Sir William Bragg Recent Experimental Physics (1) The Raman Effect.

INSTITUTION OF PETROLEUM TECHNOLOGISTS (at Royal Society of Arts), at 5 30.—Symposium on Salt Domes.

INSTITUTION OF CIVIL ENGINEERS, at 6.

INSTITUTE OF MARINE ENGINEERS, at 6.—H E. Yarrow and S Hunter, Jr Water tube and/or Scotch Boilers

Royal Sanitary Institute (at 90 Buckingham Palace Road), at 6.—Lt.-Col. W Butler and others Discussion on Recent Methods of Sewage Treatment.

Institute of Metals (Swansea Section) (at Y M C A., Swansea), at 6 15 —J Frith Application of Copper to the Building Trade

Society of Chemical Industry (Birmingham and Midland Section) (at Chamber of Commerce, Birmingham), at 6 45 —J H S Dickenson The Manufacture of Heavy Steel Forgings for the Chemical Industry

Institution of Electrical Engineers (East Midland Sub-Centre) (at Loughborough College), at 6 45 —S G Brown Loud Speakers since their Conception with Gramophone Pick ups and Wireless Recording Apparatus

Institution of Electrical Engineers (North Midland Section) (at Hotel Metropole, Leeds), at 7 —Informal Discussion on Earthing and the Safety of the Public, with special reference to Domestic Apparatus

Institution of Electrical Engineers (North Western Centre) (at College of Technology, Manchester), at 7 —Prof W Cramp The Birth of Electrical Engineering (Faraday Lecture).

Institution of Electrical Engineers (Scottish Centre) (at North British Station Hotel, Edinburgh), at 7 —O Howarth The Metering of Three Phase Supplies

Institute of Fuel (at 17 Albert Square, Manchester), at 7 —Dr G V Slottman Fuel Control in the Iron and Steel Industries.

Institution of Heating and Ventilating Engineers (Associate Members and Graduates Section) (at Borough Polytechnic) at 7

Institution of Heating and Ventilating Engineers (Associate Members and Graduates Section) (Manchester and District Branch) (at Milton Hall Manchester), at 7 —C M Oates Panel Heating

Royal Photographic Society of Great Britain, at 7 —Colour Photography

Institution of Automobile Engineers (at King's Head Hotel, Coventry) at 7 30 —S W Nixon The Compression Ignition Automobile Engine

Institution of Engineers and Shipbuilders in Scotland (at 39 Elmbank Crescent Glasgow) at 7 30 —G Wahl Electric Welding in the Construction of Sea going Vessels

Institute of Metals (North East Coast Section) (at Armstrong College, *Newcastle upon Tyne) at 7 30 —A. Wragg Stress in Metals*

Quekett Microscopical Club (Annual General Meeting) (at Medical Society of London), at 7 30 —Presidential Address

Royal Anthropological Institute at 8 30 —H J Hogbin The Spirits of the Dead at Ongtong, Java

WEDNESDAY, February 11

Institution of Heating and Ventilating Engineers (at Hotel Russell Russell Square), at 2 30 —W G Case and W E Dennison Boilers and Metals

Royal College of Physicians of Edinburgh at 5 —Dr D K Henderson Social Psychiatry (Morison Lectures) (2).

Geological Society of London, at 5 30

Television Society (at University College) at 7 —E L Gardiner The Stenode Radiostat and its Application to Television

Halifax Textile Society (at White Swan Hotel Halifax), at 7 30 —N L Hudson The Use of Liquid Fuel in the Textile Trade

Royal Society of Arts, at 8 —F G Wood New Motives for Textile Designs

THURSDAY, February 12

Royal Society, at 4 30 —Prof L T Hogben and D Slome The Pigmentary Effector System, VI —H Muir Evans Brains of Cyprinoids and Habits of Feeding

Royal Institution of Great Britain at 5 15 —Prof H Dingle The Nature and Scope of Physical Science (4).

Royal Aeronautical Society (at Royal Society of Arts), at 6 30 —Capt N Macmillan Air Navigation

Institute of Marine Engineers (Junior Section) at 7 —J Doonan The Manufacture and Uses of Monel Metal (Film Lecture).

Royal Photographic Society of Great Britain (Colour Group), at 7 —Informal Meeting

Burnley Textile Society (at Mechanics Institute, Burnley), at 7 15—R. Eastman Efficient Lighting

Society of Chemical Industry (South Wales Section) (jointly with Institute of Chemistry) (at Cardiff Technical College), at 7 30 —F J Dippy The Geochemistry of Coal

Institution of Electrical Engineers (Dundee Sub-Centre) (at University College Dundee), at 7 30.—J M Paterson Commercial Aspects of Electrical Engineering

Optical Society (at Imperial College of Science), at 7 30

Institute of Metals (London Section, jointly with Electroplaters and Depositors Technical Society) (at 83 Pall Mall), at 7 30 —Dr H J T Ellingham Electrolytic Processes in Metallurgy

North East Coast Institution of Engineers and Shipbuilders (Tees side Branch) (at Cleveland Scientific and Technical Institution, Middlesbrough), at 7 30 —A Richardson The Modern Manufacture of Machine-cut Gears

Institution of Welding Engineers (at Institution of Mechanical Engineers), at 7 45.—Declaration of the name of the winner of the Operative Welders Prize and the awarding of the Prize and Gold Medal —The Prize Winner Welding Practices and Methods based on my own Experiences

British Psychological Society (at Royal Anthropological Institute), at 8.15 —Extraordinary General Meeting

Royal Society of Medicine (Neurology and Psychiatry Sections) at 8.30 —Special Discussion on Mental Symptoms associated with Brain Tumours.

FRIDAY, February 13

Royal Astronomical Society (Annual General Meeting), at 5 —Presidential Addresses by Dr A C D Crommelin on the award of the Gold Medal to Prof W de Sitter, and the Jackson Gwilt Medal and Gift to C W Tombaugh

Biochemical Society (at Lister Institute), at 5 —W T J Morgan: A Specific Precipitating Polysaccharide from *B. dysenteriæ* (Shiga).—L F Hewitt Oxidation Reduction Potentials of Pneumococcus Cultures.—B C. Guha Investigations on Vitamin B_2.—E. Boyland and O Meyerhof Glycogen Synthesis in Muscle Poisoned with Mono-iodoacetic Acid —Gladys Bird and P Haas The Cell Wall Constituents of Laminaria. Mannuronic Acid —M G Macfarlane The Influence of Potassium Mono-iodoacetate on Fermentation by Yeast Preparations —R. Robison and E. J King Hexosemonophosphoric Esters —W Robson and J Lamb The Erlenmeyer Synthesis of Amino-acids

Royal College of Physicians of Edinburgh, at 5.—Dr D K Henderson Social Psychiatry (Morison Lectures) (3).

British Psychological Society (Æsthetics Section) (at Bedford College) at 5 30 —R Ellis Roberts Reality in Life and Literature

Malacological Society of London (at Linnean Society), at 6.

North-East Coast Institution of Engineers and Shipbuilders (at Mining Institute, Newcastle upon Tyne), at 6 —W C S Wigley Ship Wave Resistance—an Examination and Comparison of the Speeds of Maximum and Minimum Resistance in Practice and in Theory

Society of Chemical Industry (Chemical Engineering Group) (at Institution of Civil Engineers), at 6 30 —D MacDonald Silver and its Application to Chemical Plant

Institution of Locomotive Engineers (London) (at 36 George Street Manchester), at 7 —D W Sanford The Development of the Piston Valve to improve Steam Distribution

Institution of Mechanical Engineers (Informal Meeting), at 7

Society of Chemical Industry (South Wales Section, jointly with Microscopical Society of Wales) (at Cardiff Technical College), at 7 30 —C A Seyler The Microstructure of Coal

Blackburn Textile Society (at Blackburn Technical College), at 7 30 —S N Duguid Smoke Abatement and Fuel Economy

Junior Institution of Engineers, at 7 30 —H C Reid Monolith Foundations.

Institute of Metals (Sheffield Section) (at Sheffield University), at 7 30 —N C Marples The Applications of High Nickel Nickel-Copper Alloys and Pure Nickel in Industry

Royal Institution of Great Britain, at 9 —Prof F Ll Hopwood Ultrasonics Some Properties of Inaudible Sound

Society of Chemical Industry (Glasgow Section, jointly with other Chemical Societies) (at Glasgow)

SATURDAY, February 14

Royal Institution of Great Britain, at 3 —J Stephens On the *Reading and Speaking of Verse (1) On Speaking Verse.*

PUBLIC LECTURES.

SATURDAY, February 7

Gilbert White Fellowship (at 6 Queen Square, W C 1), at 3 —Prof E J Salisbury Some Rarer British Plants and their Distribution

Horniman Museum (Forest Hill), at 3 30 —Dr F A. Bather The Cuttle Fish and its Ancestors

MONDAY, February 9

University of Cambridge (Cavendish Laboratory), at 4 45 —Dr Irving Langmuir Fundamental Phenomena in Electrical Discharges in Gases (Scott Lectures) (Succeeding Lectures on Feb 11, 13 16, and 18)

London School of Hygiene and Tropical Medicine (Public Health Division), at 5 —Col L W Harrison Venereal Disease Gonorrhoea

University of Leeds, at 5 15 —H B Butler Some International Aspects of the Economic Depression

TUESDAY, February 10

Imperial College—Royal School of Mines, at 5 30 —Dr F G Gregory Growth Problems in Plants. (Succeeding Lectures on Feb 17 and 24)

University College London, at 8 15 —Miss E Jeffries Davis Re plannings of London, c 1520–1920

WEDNESDAY, February 11

London School of Hygiene and Tropical Medicine (Public Health Division), at 5 —Col L W Harrison Venereal Disease Syphilis.

Royal Anthropological Institute (at Portland Hall, Great Portland Street W 1), at 5 30.—C O Blagden Peoples of British Malaya.

King's College, London, at 5 30 —Prof E Prestage The Great Age of Discovery (4) Vasco de Gama and the Way to the Indies

University College, London, at 5 30 —I C Grondahl Norwegian Life and Character (Succeeding Lectures on Feb 18 and 25)

Belfast Museum and Art Gallery, at 8 —Prof J K Charlesworth Big Animals of the Past.

THURSDAY, February 12.

Bedford College for Women, at 5 15.—*Mrs Brajlal Nehru* The Position of Women in India.

King's College, London, at 5 30 —S. P Turin Workers Family Budgets in Russia and Great Britain before and after the Great War

SATURDAY, February 14

Horniman Museum (Forest Hill), at 3.30.—Major G M Coombs Fiji and the Fijians.

CONFERENCE.

Wednesday, February 11

Conference on the Making of New Grassland Experiences of Practical Farmers (at the Rothamsted Experimental Station), at 11 30 a m —Chairman Earl de la Warr Speakers Prof F L Engledow, J Cruickshank, W M Findlay, J Keith, A. R. McDougal W S Mansfield, J Alston, C H Gardner, A. MacArthur

Science and Transport.

IN few if in any departments of civil or industrial life has applied science introduced more revolutionary changes in the last hundred years than in that of transport It would be difficult, however, to find any other aspect of civil life which has been allowed to develop along more haphazard lines or in which the utilisation of the results of scientific discoveries has been more divorced from scientific organisation and control One and a half million people, or nearly eight per cent of the employed population of Britain, are directly engaged in one or other of the branches of transport Regarded solely as an industry, it is, therefore, of the utmost importance that efficient management and wise administration should maintain the highest possible standard of efficiency and economic development of the transport industry From the wider view of transport as an integral and indispensable part of the national structure, it is impossible to exaggerate the importance of adequate, efficient, and cheap transport facilities, particularly in a country such as Great Britain, in which trade consists so largely in the importation of food and raw materials and the exportation of manufactured goods

The Royal Commission on Transport alludes in its recently published final report * to the casual and haphazard way in which earlier forms of transport, particularly road transport, have been allowed to develop, and while regarding air transport as outside the scope of its inquiry, expresses the hope that timely guidance will ensure the development of this infant form of transport along sound lines Many of the main difficulties in the present situation are indeed, as in the case of London, the result of lack of vision on the part of everyone concerned The continued unchecked or uncontrolled development of road transport in competition with rail transport will undoubtedly have very serious evil results, and, apart from affecting the financial stability of those who provided transport facilities, will also hamper the economic progress of the nation

The case of the railways provides a classic example of the burden which ignorance and prejudice can place on posterity, and the extremely high prices which in the nineteenth century our railways were compelled to pay for land to buy off influential opposition are an important factor in their present-day difficulties, and one from which other countries are relatively free It is to be hoped that the lesson has been sufficiently well learnt to ensure general support for the Commissioners' recommendations

* London H M Stationery Office Cmd 3751

regarding compensation in the case of privately owned bridges carrying public highways

The report by no means holds the railways free from responsibility for some of their present difficulties To some extent the 'grouping' under the Railway Act of 1921 is unscientific and not sufficiently geographical To scientific minds the criticism in regard to the speed of railway journeys, particularly long-distance runs, will appear not a little scathing, and the railways are reminded that facilities create traffic

On the broad issues as between road and rail transport, the report stresses the advantage of rail transport in the case of long distances and heavy loads, and few of the recommendations can be more unquestionable than that which asserts that it is not in the national interest to encourage the diversion of heavy goods traffic from the railways to the roads Such diversions add greatly to the expenditure on highways, and tend to make the railways unremunerative without conferring any commensurate advantage As regards long distance travel, the railways have not made full use of their immense advantage of speed, and there is little doubt that with a little more attention to the amenities of railway travel on the lines recommended, medium- and long distance passenger road transport would largely disappear as a result of diminished demand

The report considers that much of the competition between road and railway and other forms of transport is due to the fact that the wages and general conditions of service in the road haulage industry leave much to be desired, and Sir W G Lobjoit's reservation on the recommendation for licensing of road hauliers was due not to any doubt as to the unsatisfactory conditions of wages and of labour, but to doubts as to the possibility of imposing conditions upon small firms and owner drivers The labour aspect of road transport is, indeed, of fundamental importance, not only from the economic aspect in securing fair and satisfactory conditions of wages and hours of work, as well as in eliminating unfair competition and diversion of traffic into channels not to the public advantage, but also from the safety point of view Insufficient attention has been given to the health and general physical fitness of transport drivers In particular, the establishment of hostels or rest-houses for long-distance drivers, who form one of the occupational classes most highly infected with venereal disease, is a provision much needed if the efficiency of the driver is to be maintained and this serious factor in the causation of road accidents eliminated

On the policy adopted by the railways of meeting road competition by themselves developing road transport, the Commission, while welcoming it so far as better co ordination of rail and road transport is secured, makes the trenchant comment that the large capital sums expended in establishing such services would be better applied to the electrification of suburban lines It is to such electrification, the improvement of omnibus services, and possibly to tube railways, that the Commissioners obviously look for the handling of the passenger traffic in large cities like London, Glasgow, Liverpool, Manchester, etc, at certain 'rush' hours, in place of the tramway systems, which they condemn as obsolete

An important feature in transport development to which the report directs attention is that of research on road problems and the ceaseless endeavour to ensure that the highway is adequate not only for the traffic it has to bear at the present time, but also for that which it is likely to carry in the future Much valuable research is being carried out by the Ministry of Transport, with the collaboration of the National Physical Laboratory, on such matters as the effects of varying certain factors in the design and construction of concrete roads, the conditions which give rise to the skidding of vehicles, and the effect of variations in the wheel diameters in the damage caused to roads To enable experiments to be carried out under practical conditions without interference from general traffic, and to enable particular road surfaces to be studied under known traffic conditions, a special experimental road has been constructed near an experimental station

Experiments have been carried out on glare on roads and on other problems of illumination relating to transport under the Illumination Research Committee of the Department of Scientific and Industrial Research The Bridge Stress Committee, in co operation with the railway companies, has carried out an investigation on stresses in railway bridges, in which 52 bridges were tested and some forty different types of locomotives used, the work resulting in the withdrawal from service of certain classes of locomotives and in improved locomotive designs to reduce the unbalanced vertical forces responsible for the 'hammer-blow' and the resultant dangerous oscillations in bridges, as well as in the development of practical formulæ for bridge designers These and similar activities assist the development of modern methods of transport on scientific lines, and the condemnation of steel tyres and the recommendation that all mechanically propelled vehicles using the roads, other than light

and heavy locomotives and steam rollers, should be fitted with pneumatic tyres, are essentially based on scientific investigation and evidence

The main difficulty, however, is that of securing action along the lines indicated by scientific and impartial examination when a large number of authorities and interests, some of which may be seriously conflicting, are involved This is possibly illustrated by the failure of the Commission to make any real recommendation in regard to unification, the importance of which is clearly recognised Beyond the final recommendation for the appointment of a permanent Advisory Council on Transport, the discussion of co-ordination leads to no unanimous conclusion In this respect the report differs from the two earlier reports on "The Control of Traffic on Roads" and on "The Licensing and Regulation of Public Service Vehicles", the unanimous recommendations of which were practically all incorporated in the Road Traffic Bill which received Royal Assent on Aug 1, 1930 As the report makes clear, however, the question of co-ordination and unification is of fundamental importance It must ultimately be determined largely on scientific principles, and the modern traffic problem is essentially one of those problems set by scientific developments the solution and control of which rests with scientific workers themselves

The Theory of Geological Thermal Cycles

The Surface-History of the Earth By Dr John Joly Second edition Pp xxi + 211 + 13 plates (Oxford Clarendon Press, London Oxford University Press, 1930) 8*s* 6*d* net

A BOOK which has for its chief object the exposition of a group of geological hypotheses of a highly speculative character is likely soon to become out-of-date as geophysical evidence accumulates and as quantitative criticism is applied to processes envisaged in the light of incomplete knowledge This fate rapidly befell the first edition of Prof Joly's well known book It is therefore of special interest to consider how the author has dealt with recent advances bearing on his theory of thermal cycles and with the various criticisms, adverse or constructive, that represent the reactions towards it of other workers in the same field Judged in this way, the second edition can only be regarded as disappointing

Any discussion of the distribution of the radioactive elements in the earth must be based on the nature of the rock-types entering into the layers of the crust and of the underlying substratum The xenoliths brought up from the depths by the kimberlite magma of the diamond pipes of Africa suggest that the downward distribution is from granitic and gneissic rocks through amphibolite and granulite to eclogite and peridotite Seismic evidence is consistent with such a sequence, but it fails to support Joly's new suggestion that the granite layer may be underlain by an anorthosite layer (p 64) Moreover, the diamond pipes have provided no samples that would lend support to this assumption Joly's view that eclogite is an important constituent of the upper part of the substratum is less hypothetical, but it is far from safe to assume that the radioactivity of such a layer is necessarily the same as that of the eclogites tested in the laboratory, since these occur for the most part in mountain belts where they owe their origin to exceptionally high pressure If the plateau basalts have been derived from the complete fusion of an eclogite layer, then the radioactivity of the latter is more likely to be represented by that of the former, as assumed in the first edition By regarding the radioactivity of the substratum as thermally equivalent to about one-third that of the plateau basalts, Joly now considers the period of liquefaction to be about three times as long as his original estimate Unfortunately, even this admission fails to make the consequences of the hypothesis consistent with the duration of geological time as estimated from lead ratios

Much more serious, however, is the fact that Joly's mechanism of alternating accumulation and discharge of heat seems to be physically unacceptable Jeffreys has vigorously attacked the hypothesis of thermal cycles, on the grounds that on the postulated conditions the substratum would remain permanently fluid, and that tidal drift of the crust would not occur at the required rate But even though the proposed mechanism for bringing about the discharge of excess heat is unsatisfactory, Joly has nevertheless rendered a most important service to geology by facing the probability that there *is* an excess of heat to be discharged, and that some form of crustal drift is necessary to avoid the *impasse* of a thermally expanding globe Possibly the underlying flaw in Joly's preliminary assumptions is his belief that because the substratum is now solid in the sense of being rigid and highly viscous, it is therefore necessarily crystalline It may not be, at least below a certain level, quite as probably it is in a glassy state Granting the latter assumption, which is difficult to resist from the thermal point of view, there is no difficulty in discharging heat

by convective circulation in the substratum combined with continental drift in the crust, the currents themselves providing the motive force for 'engineering' the drift Such a process has been already suggested (*Geol Mag*, May 1928, p 236), and it has apparently been overlooked by Joly when he says on p 99, "no imaginable physical system which results in conditions of steady heat-flow to the surface can account for those periodical events which are at the basis of geological history and which have hitherto constituted its most elusive problem"

Lotze has assailed both Joly's hypothesis and the modifications proposed by the reviewer in 1925 by confronting them with the actual complexities of earth history It must be admitted that an alternation in time of world-wide compression with world-wide tension cannot be readily admitted Tensional phenomena in some regions seem, on the contrary, to be contemporaneous with compressional phenomena elsewhere On the convection hypothesis this would be inevitable, on the theory of thermal cycles it remains inexplicable

Of the first edition of Joly's book it was possible to write, "Prof Joly's inspired originality should henceforth lead geology into a new phase" (NATURE, Dec 19, 1925, p 891) This forecast has already been amply justified, and although the second edition lags behind the progress that has been made possible by the first, the book remains a record of one of the most highly stimulating and suggestive contributions ever made to theoretical geology ARTHUR HOLMES

The Yellow-skinned Races of South Africa.

The Khoisan Peoples of South Africa Bushmen and Hottentots By Dr I Schapera (*The Ethnology of Africa*, edited by J H Driberg and Dr I Schapera) Pp xi + 450 + 16 plates (London George Routledge and Sons, Ltd, 1930) 31*s* 6*d* net

WE have long needed an authoritative work on the Bushmen and Hottentots of South Africa The former are an extremely important people for the ethnologist, and from them the Hottentots cannot be dissociated physically or culturally, hence the composite name "Khoisan" adopted by the author—Khoi = Hottentot and San = Bushman. We are therefore grateful to Dr Schapera for taking the trouble to assemble all the available data concerning these peoples and therewith to make a trustworthy and interesting book which will be indispensable for students

The Bushmen are relatively late-comers into South Africa from East Africa; they were preceded by the 'Boskopoid' race and doubtless by other races yet to be identified The Rhodesian man of Broken Hill, who belonged to a much more primitive race, is not mentioned, evidently as he did not contribute anything to the Khoisan Still later than the Bushmen came the Hottentots, they appear to have sprung out of a mixture of the old Bushman population of East Africa with an early immigration there of Hamites, who gave them cattle and those peculiarities of language by which they are distinguished from the modern Bushmen The southern Bushmen represent the purest type, while the northern tribes show some degree of intermixture with other peoples, as their greater stature and darker colour suggest

The Hottentots as a whole are a fairly uniform people, their skulls, according to Shrubsall, seem to indicate that there was a Bantu Negro mixture which perhaps took place before their arrival in South Africa The Korana branch of the Hottentots are somewhat aberrant, they certainly have absorbed much Bantu blood, but there seem to be cranial indications of a Boskopoid element in their composition

The greater part of the book deals with the culture of the Bushmen and Hottentots, which complicated subject is attacked by Dr Schapera in a workmanlike manner, as is to be expected from a former student of Prof A R Radcliffe-Brown The Bushmen have never been systematically studied by a trained ethnologist and the information is fragmentary and occasionally contradictory This has made it impossible to come to definite conclusions on many points, and it is to be hoped that these debatable matters will be settled by work in the field before it is too late, if it be not so already A noticeable feature of the book is that the physical conditions under which the people live and their economic life are given due prominence, and the inter-relationship of these with the socio-religious life of the people is not overlooked

The mimetic animal dances of the Bushmen were probably of a ritual character, but of their function and relation to the social life generally, scarcely anything is known Purely decorative art is rare and very poorly developed, but their pictorial art, consisting of paintings and engravings executed on rock surfaces, is well known It has for a long time been recognised that the paintings are of different styles and that some are superimposed on others, thus giving a relative chronology, recently Mr M. C Burkitt has demonstrated an interesting sequence,

but there is much yet to be discovered in studying a wider area

The only Hottentot people whose social organisation is at all well known are the Naman of the south-west, of whom a special study from this point of view has been made by Mrs A W Hoernlé Her description has been supplemented in several respects by the observations of other writers, so that it is possible to arrive at a fairly clear conception of the social structure of this division, but the original organisation of the other Hottentot peoples has long since been totally obliterated

There is ground for supposing that the Hottentots formerly revered the moon Apart from invocations to the moon, their religious cult seems to have centred mainly in the worship of heroes, derived partly from animistic beliefs, partly from a personification of the natural forces producing rain In a country like South Africa, where water is in places exceedingly scarce, it is not surprising that the annual rain ceremony is the most important religious ceremony of the Hottentots The Hottentot religious conceptions show in many respects a striking resemblance to those of the Bushmen The southern Bushmen to some extent stand apart from the rest, they share with the others the cult of the moon and several beliefs concerning the dead and natural phenomena, but the beliefs centring in the Mantis among the Cape Bushmen have no parallel farther north Their mythology is far more elaborate than that of the Hottentots, which in its turn is more developed than that of the northern Bushmen

There is a chapter on the difficult subject of the Khoisan languages, an exhaustive bibliography, and numerous excellent photographs If the other volumes of this series prove to be as good as this one, we shall have a very valuable collection of monographs on African ethnography

A C HADDON

Modern Farming in Germany

Handbuch der Landwirtschaft Herausgegeben von Fr Aereboe, J Hansen und Th Roemer Fünf Bände Lieferungen 12 25 (Berlin Paul Parey, 1929) 5 80 gold marks each part

NOW that the publication of this handbook is complete, it is possible to form the comprehensive view of the whole work that was defeated earlier by its fragmentary method of production With all the parts in hand, the objection based on non-consecutiveness is reduced to a problem for the bookbinder

The complete handbook is admirable One could not, if one wished, withhold admiration from a work on agriculture on a scale commensurate with the size of the subject here the five volumes cover more than 3000 pages, and weigh, unbound, some ten kilograms In addition to quantity, quality is undoubtedly present The specialists who contribute know their subjects, the aim of the whole work is both to lay a foundation for the farming of the coming hundred years and to help the industry through its present crisis, and even if this may seem a little ambitious, the result has been good While the book does not go deeply into fundamentals, on the practical side it covers the best of existing farming methods (using 'farming' in an extremely wide sense), describes ways of improving them, and introduces new ones The reference, not unnaturally, is almost always to German conditions, for English readers the book will be useful chiefly as a fund of information about German farming, both in organisation and in details of its execution Whenever one wants to know how so and so is done in Germany, it will be natural to turn first to this handbook

The twenty eight separate contributions that are included in the fourteen parts here assembled can scarcely be reviewed individually All the volumes except that dealing with the principles of arable farming (vol 2), which was completed in the earlier instalments, are represented that is to say, much of the economics of farming (vol 1) and of general animal husbandry (vol 4), almost the whole of crop husbandry (vol 3), with a special section on agricultural machinery, and of special animal husbandry (vol 5) In the first and fourth volumes the individual contributions cover a certain aspect of the general subject, while in the third and fifth volumes a single type of crop or live stock is described in each contribution

Many of the contributions are so thorough and informative that they are worth purchasing on their own merits investigators who would not in any case buy the whole handbook might be recommended to get the sections bearing on their own work Since the handbook was published in parts, this should easily have been arranged—but actually the method of production makes it decidedly difficult The obstacle, which has been referred to in a review of the earlier instalments, is a lack of correlation between the parts as published and the actual sections of the handbook, it could have been obviated when publication was complete by a summary table indicating the numbers of the parts in which each contribution appears This has not

been done, however, the information cannot be found either in the publisher's announcement or in the general table of contents printed in the cover of each instalment In consequence, the advantage from the reader's point of view of publication in separate parts has been lost

The Physiology of Micro-organisms.

Physiology and Biochemistry of Bacteria By Prof R E Buchanan and Prof Ellis I Fulmer Vol 1 *Growth Phases, Composition and Biophysical Chemistry of Bacteria, their Environment and Energetics* Pp xi + 516 34s net Vol 2 *Effects of Environment upon Microörganisms* Pp xvii + 709 34s net Vol 3 *Effects of Microörganisms upon Environment, Fermentative and other Changes Produced* Pp xv + 575 34s net (London Baillière, Tindall and Cox, Vol 1, 1928, Vols 2 and 3, 1930)

THE treatment of the subject, as may be seen from the size of the work, is exhaustive, yet the authors do not consider that they have presented more than an introduction to, or an outline of, our knowledge of the physiology and biochemistry of the bacteria, yeasts, and moulds In their opinion, many of the topics discussed could profitably be submitted to monographic treatment, but limitations of space prevented them from carrying out such an elaboration Their purpose, therefore, was to compile and systematise the material relating to the physiology of micro organisms, they have well succeeded in their monumental task The biblio graphies of literature cited run to 30, 110, and 140 pages respectively in the three volumes the whole work brings under one cover abstracts of papers scattered in a variety of journals, arranged according to the divisions of the subject selected by the authors The treatise forms, therefore, a very useful work of reference

Many will find the work also of value from another point of view, each section is preceded by a general discussion of the physical or chemical principles involved, which alone would be useful as an intro duction to certain aspects of biochemistry Thus there are extensive discussions of such subjects as the physical and physico-chemical characteristics of systems of various degrees of dispersion, the different types of energy and chemical thermodynamics, the velocities of chemical reactions and the effects of temperature changes upon them, the characteristics of certain electromagnetic waves and the characteristics of enzyme action and a classification of enzymes Free use is made of chemical formulæ throughout Whether such exhaustive discussions should find a place in a work of this type is perhaps doubtful, but there is no question as to their value for many workers who may not wish to be referred to the larger text-books of biochemistry

The titles of the volumes give some idea of the scope of the work, but further details may be given to illustrate its comprehensiveness In the first volume, a chapter is devoted to growth phases and growth rates in cultures of micro-organisms, in which may be found details of different methods of counting the numbers present in a given volume the subject lends itself to a mathematical treatment The chemical composition of the cells of micro-organisms is next considered the account of bacterial pigments forms an interesting section Brief reference is also made to the recent work on the antigenic polysaccharides The section on the physico-chemical characteristics of systems of various degrees of dispersion is one of the most complete in the book and includes discussions on the properties of true solutions, surface tension, adsorption, viscosity and osmotic pressure, on the Donnan equilibrium, on conductivity and hydrogen ion concentration and the electrometric and colori metric methods of measurement of the latter, and on the properties of colloids

From that point the transition to the agglutination of bacteria by various agents is natural and easy Reference is made to agglutinins, antitoxins, opsonins, and antibodies, familiar to the human pathologist and bacteriologist The final chapter of this volume deals with the energy relationships of bacteria, especially the energy changes in oxidations and reductions carried out by them, and the utilisation of energy in synthesis, in the production of light and of movement, as for example in chemotropism

The chapters in the second volume will be of interest to a wide circle of readers The effects of temperature, of rays and emanations, and of various physical environments are described in detail apart from the general scientific interest of the descriptions, human pathologists will find them of value from the point of view of the destruction of micro-organisms by the various agents cited, as well as of the changes in pathogenicity which can be induced In succeeding chapters the effects of the chemical environment are considered the treatment is systematic, inorganic compounds and their ions, non nitrogenous and nitrogenous organic compounds being taken in order Here the action of germicides may be found described in detail The presentation of the structural formulæ of all the

compounds considered lends an added value to these chapters in fact, they may be of use as a source of reference to those who wish to know the structure of a number of complex organic substances, including the antiseptic dyes

The third volume deals with the changes produced in various compounds by micro-organisms and the agencies by which these are effected one chapter is devoted to symbiosis The arrangement of the subject matter is on the same lines as in the second volume An important section is that dealing with fermentation Structural formulæ are again freely used

It is impossible in a short review to give more than an outline of the scope of the treatise, but enough has been said to show the wide appeal of the work It is up-to-date, although in a science which is advancing so rapidly, revision with our increasing knowledge will in places be required, as the authors themselves acknowledge Their desire that the work should indicate not only what has been accomplished, but also what remains to be done, appears to have been fully realised It should be in the hands of all bacteriologists, as well as of those who have to deal with similar chemical processes carried out by the higher organisms The volumes are clearly printed, and each is provided with three indexes, to authors, to subjects, and to micro-organisms

Our Bookshelf.

Guide to the Study of Animal Parasites By Dr William A Riley and Reed O Christenson (McGraw-Hill Publications in the Zoölogical Sciences) Pp xv + 131 (New York McGraw Hill Book Co, Inc, London McGraw-Hill Publishing Co, Ltd, 1930) 7*s* 6*d* net

This work is the outgrowth of Prof Riley's fifteen years' experience in presenting the main facts of parasitology to students in the laboratory The authors suggest that the first two practical periods should be devoted to a general survey of the parasites of the frog—*Trypanosoma* and *Lankesterella* (wrongly spelt throughout the book) in the blood, Helminthes in the lungs, alimentary tract, and bladder, and Protozoa in the large intestine and kidney Attention is then directed to the Trematoda, represented by *Polystomum*, *Clonorchis*, and *Fasciola*, and a key to the chief groups of cercariæ is added The study of cestodes begins with that of *Tænia pisiformis*, after which the human tænias and representative species of *Hymenolepis*, *Dipylidium*, *Diphyllobothrium*, *Multiceps*, and *Echinococcus* are briefly considered *Ascaris*, the hookworms, *Trichinella*, and *Trichuris* are the Nematoda chosen for examination

Instructions are given for the examination of fæces for eggs (with a key to the eggs of helminthes in human fæces) and of small mammals for adult worms The section of the work on Protozoan parasites deals successively with *Entamœba histolytica* and *coli*, *Trypanosoma lewisi*, *Giardia* and other flagellates, *Monocystis*, *Eimeria*, human and avian malaria, *Babesia*, *Sarcocystis* and the ciliates of the frog's rectum Suggestions are added on the use of text books, journals, and indices relating to parasitology, on the collecting, preservation, and mounting of specimens, lists are given of the more important parasites of the cat, dog, pig, sheep, rabbit, rat, fowl, and frog, the organ infected being indicated, references to works on parasitology, chiefly in English, are appended, and there is an adequate index

The lists of parasites would have been shortened without impairing their value to the student by omitting species rarely recorded *Sarcocystis*, common in the muscles of the sheep and the rat, and perhaps the trypanosome not infrequently present in the blood of the rabbit, might have been included in the lists

The information and instructions set forth in the book, supplemented, as no doubt is the case, by additional details on anatomy and life-history given in the laboratory, form a sound practical guide to the beginner in parasitology

The Unknown Self a New Psychological Approach to the Problems of Life, with Special Reference to Disease By Dr Georg Groddeck Pp 207 (London The C W Daniel Co, 1929) 7*s* 6*d* net

This little volume has been translated with the object of introducing the point of view of Dr Groddeck to English readers It consists of a series of short papers written at different times and for different audiences, but all informed by the same spirit He has sought to understand *why* people get ill, in order to help them to get well Although in sympathy with, and an exponent of, the psycho analytic theory, yet he cannot be located to any one school of thought or therapeutic practice He is in line with the thinkers who, at various times, have arisen as rebels against an intellectualism that would interpret the whole human being on materialistic lines

The elusive prospect of being able to comprehend humanity on mechanical principles has always appealed to some thinkers Galen in the second century criticised the narrow mechanical school of the methodists, while the misdirected application of the brilliant development of the so-called mechanical sciences in the seventeenth century stimulated Stahl to his polemical defence of a unifying animating principle over and above the machinery of life Groddeck postulates an unknown and for ever unknowable force in man, which, for purposes of exposition, he calls the 'It' The It is not merely the unconscious of the psycho-analytic school, but "includes both conscious and unconscious processes and holds absolute sway over the activities which it has built up There is no opposition between the ego and the It, rather is the ego a function of the It" No adequate definition

of the It can be given, but the author maintains that the reality of its existence is demonstrated constantly in everyday life, which "is an uninterrupted revelation, a continuous self-exposure of the It"

The first part of the book is concerned with setting out the more theoretical aspects of the theory, while in the clinical communications the application of the theory to the diagnosis and treatment of various common complaints is given While there is much in the book that readers will find difficult to understand, they will not find it dull, while even the orthodox, if they are not too old in thought, will find it stimulating and challenging

Elements of Forestry By Franklin Moon and Prof Nelson Courtlandt Brown Second edition, revised and reset Third printing, corrected Pp xvii + 409 (New York John Wiley and Sons, Inc, London Chapman and Hall, Ltd, 1929) 17*s* 6*d* net

MOON and Brown's "Elements of Forestry" has had a wide popularity in the United States First published in 1914, a second edition was issued in 1924, and now a revised and corrected third printing In this latter, the entire text has been revised and corrected, particularly with reference to up to-date statistics, new facts made available or recently determined, and in other ways the text has been brought up-to-date The authors state that they "have purposely left out many statistics and figures, such as prices, which change from time to time" In a book presumably used as a text book this is a wise decision, which the authors' experience since the first publication of the book will have shown desirable

The scope of this book is far wider than any of its type we remember in Britain The range of sub jects dealt with in its 387 pages (omitting appendices) covers the whole business of forestry from the elements of sylviculture (after a preliminary chapter on forestry and its meaning and importance), forest protection, forest mensuration, lumbering, wood utilisation, wood technology and preservation, forest economics, and forest finance A description of the United States Forest Service and the State forest activities follows, the book concluding with some regional studies of forest regions in the United States For anyone possessed of some considerable knowledge and training in forestry and what it aims at, this book should prove of very great interest and merits its popularity Whether it is equally useful for the student is perhaps more doubtful—since the treatment of many of the branches dealt with has of necessity been brief, condensed, and rather perfunctory, owing to the limits of space placed upon the authors

A Text Book of Economic Zoology By Prof Z P Metcalf Pp x + 392 (Philadelphia Lea and Febiger, 1930) 4 dollars

THE chief interest in foreign text-books is to see how other peoples meet problems of education In a southern agricultural State such as North Carolina, which stretches from the Allegheny Mountains to Cape Hatteras, it is important that students should be taught about the pests and parasites of man and his crops But it is still more necessary in a higher educational college that the professor should make his students think for themselves The author's science is 'systematised knowledge', but facts are barren to the student unless he is helped to consider the laws and proximate causes relating to them Surely here the professor is attempting an impossibility in dealing with the phyla of the animal kingdom in rotation, defining their characters, etc, without his class having acquired any knowledge of the anatomy of any animal in relation to the functions common to all animals There is, too, a lack of balance, 37 pages of bird classification as compared with 3 pages for fish, while important diseases like bilharzia, sleeping sickness, hookworm, etc, surely deserve fuller treatment

The book has potentialities and its tables and illustrations are good, while the list of economic animals is very complete, especially the ticks and mites A central theme is necessary, but this we failed to find We suggest that a short discussion of the facts of evolution and heredity is essential to the intelligent reading of a text book of zoology

A Study of the Oceans By Prof James Johnstone Second edition Pp viii + 235 (London Edward Arnold and Co, 1930) 10*s* 6*d* net

PROF JOHNSTONE'S study of the oceans is brief but it touches many aspects of the subject After a chapter on the origin of the earth and the geological history of the oceans and continents, he goes on to discuss the classical geography of the oceans, tracing the development of knowledge, mainly of the superficial extent of the oceans, up to the present time The second half of the book contains chapters on the physical and human geography of the great ocean basins No one could complain of lack of interest in the volume, but it is possible to suggest that too much has been tried within the compass of some two hundred pages The present issue is the second edition, which differs from the first mainly by the addition of a number of short appendices on isostasy, the Wegener hypothesis, methods of navigation, and the tides There are numerous sketch maps

La photographie d'amateur Par Dr Rémi Ceillier (Bibliothèque pratique de l'amateur) Pp 96 (Paris J-B Baillière et fils, 1930) 6 francs

THIS little book contains a considerable amount of useful information on photographic apparatus and the use of it, and the photographic processes that amateurs are generally interested in It will help the photographer to understand his work We think it is a pity that the book has no index, and that the table of contents consists only of the short headings of the seven chapters of which it consists Some of the lesser-used printing methods, such as carbon, bromoil, etc, are passed over with a mere mention, presumably so that the space available may be devoted to the more important subjects of lenses, cameras, and negative-making

Letters to the Editor.

[The Editor does not hold himself responsible for opinions expressed by his correspondents Neither can he undertake to return, nor to correspond with the writers of, rejected manuscripts intended for this or any other part of NATURE *No notice is taken of anonymous communications*]

Constitution of Osmium and Ruthenium

THESE two elements yield volatile tetroxides and by means of these their mass-spectra have now been obtained Osmium tetroxide was first experimented with, its action on the discharge, even in the smallest amounts, is quite amazing The whole mechanism of current flow is violently disorganised and only slowly recovers In consequence the admission could only be by very small periodical doses during the exposure, and it was only with the greatest difficulty that spectra of adequate density were obtained These indicate four strong isotopes and two very weak ones, one of the latter being isobaric with tungsten, W^{186} Fortunately it was easy to photograph on the same plate several short exposures of the mercury group, which is sufficiently near in mass to provide a reasonably reliable density scale The mass numbers and provisional relative abundance are as follows

Mass number	186	187	188	189	190	192
Percentage abundance	1 0	0 6	13 5	17 3	25 1	42 6

Lines at 206, 208 due to OsO are close enough to Hg 202, 204 for a rough value of the packing fraction of osmium to be obtained This appears to be $-1\ 0 \pm 2\ 0$, about that expected These results combine to give a chemical atomic weight of $190\ 31 \pm 0\ 06$ and suggest that the present one of 190 9 is considerably too high

Operations which were difficult with the osmium compound were found to be nearly impossible with that of ruthenium Not only did the vapour rapidly attack the grease of the admission stopcock, but also the presence of mercury in the doubly charged form interfered seriously with the identification and measurement of the ruthenium lines Every device was tried to eliminate the mercury lines, but only on one spectrum were they so reduced that it was possible to draw conclusions that ruthenium had six isotopes with the possibility of an extremely faint seventh The following figures, which are only rough estimates from the photometry of the faint lines, are the best available

Mass number	96	(98)	99	100	101	102	104
Percentage abundance	5	?	12	14	22	30	17

Assuming the packing fraction to be about -6, these give an atomic weight of 101 1 The present chemical value is 101 7, but as the lines 99, 100, and 101 are certain to have been enhanced a little by mercury, although its lines at 99 5 and 100 5 could not be seen, the divergence can be partially accounted for Of the isobaric pairs 96, (98), 100 which ruthenium forms with molybdenum, the first is of unique interest, for should the doubtful isotope of zirconium (Zr^{96}) be confirmed, there would exist an isobaric triplet, an occurrence of great interest and so far unknown F W ASTON

Spectrum of Cosmic Rays

SINCE 1928 I have been carrying out experiments on the absorption of cosmic rays in Lake Constance, which is 250 m deep and lies 395 m above sea level I was able to follow the cosmic rays to a depth of 236 5 m Analysis of the absorption curve showed four components of different penetrating power

The results were obtained by means of a registering electrometer specially designed for this purpose, which combined a wide range with great sensitivity The declining throw of the filament was registered on a stationary photographic plate by means of a lamp that illuminated the filament for a few seconds once an hour from the side, thus giving a bright line on a dark background The electrometer was connected to an ionisation chamber consisting of a steel cylinder of 33 5 litres capacity and 1 cm thick filled with carbon dioxide at about 30 atm pressure The entire apparatus could be made water tight, and was anchored in the middle of the lake and suspended at various depths with the help of floats

The first experiments, in October and November 1928, showed that the cosmic rays could be traced and measured to a greater depth than R A Millikan and C H Cameron have stated (Cf *Phys Rev*, **31**, p 921, 1928) These authors found that between the depths of 57 m and 67 m below the surface of the atmosphere no further decrease in ionisation could be observed in their apparatus On the other hand, my observations of 1928 showed (cf *Naturw*, **17**, 183, 1929)

At a depth of	78 6 m	an ionisation of		1 65	volts per hour	
,,	105 2	,,	,,	1 31	,,	
,,	153 5	,,	,,	1 00	,,	
,,	173 6	,,	,,	0 93	,,	
,,	186 3	,,	,,	0 89	,,	
,,	230 8	,,	,,	0 83	,,	

Subsequent experiments in the winter of 1929–30 proved that the decrease in ionisation at greater depths had not been caused by a decrease in the radioactivity of the water towards the bottom of the lake In these experiments the ionisation chamber was enclosed in a protecting tank 2 5 m in diameter, which was filled with water from the surface of the lake When the apparatus was sunk to various depths a constant layer of water 1 m thick shielded the ionisation chamber from the radioactivity of the water outside The results

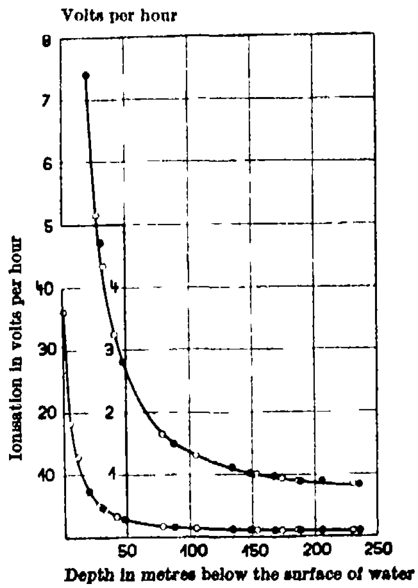

FIG 1

obtained in this way are in complete agreement with the curve plotted in 1928 without the protecting tank, a slight correction of 0 05 volt per hour being applied to account for the altered residual ionisation The former values are thus shown to be independent of the radioactivity of Lake Constance Fig 1 shows all the

points obtained, those without the tank being marked by circles the others by black dots The experiments below 20 m of water are reproduced on a tenfold scale Fig 2, showing the values below 75 m of water

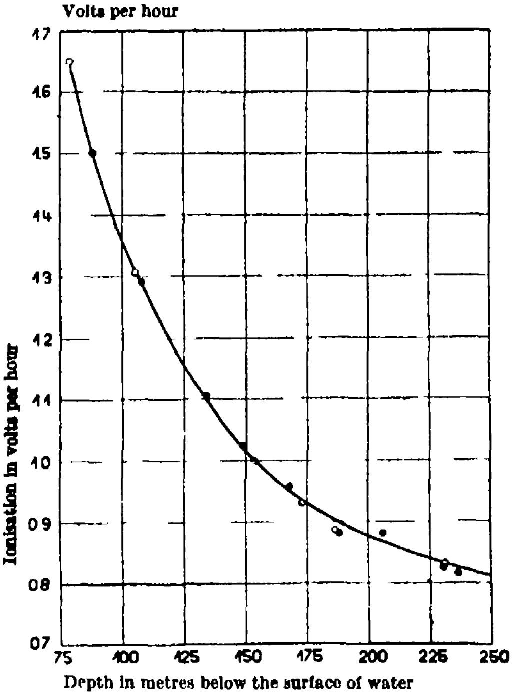

FIG 2

on a still larger scale may serve to illustrate the accuracy of measurement

In August and September 1930 the results were tested again with the help of a Geiger Muller electron counter tube which was sunk to various depths and acted on an electric clock the dials of which were photographed automatically at fixed intervals The results obtained are given in the following table

Depth in m below surface of water	Total period of the series of registrations	Average number of impulses per hour	
0	1 hour	7920	The residual impulses (about 500 per hour) due to the apparatus have been subtracted
(about 1)	[illegible]	5500	
(about 3)	[illegible]	4840	
7	[illegible]	3610	
9	1	3350	
18	[illegible]	2000	
34	3 hours	867	
93	4½	172 5	
133	4	88 5	
183	5½	52 5	
235	28	13	

From 7 m downwards the absorption curve of the cosmic rays obtained with the electron counter tube is in good agreement with that gained by the ionisation method Nearer the surface the readings of the electron counter tube are relatively too low This is probably due to the electrical and mechanical lag of the registering apparatus

The analysis of the absorption curve was made by my collaborator Herr W Kramer assuming incidence of the rays from all directions and taking the scattered radiation into account (cf H Kulenkampff, *Phys Zeits* **30**, 561 1929) Four components resulted The relative intensities of the hardest three components on entering the atmosphere are 0 81 6 4 16 35, the hardest radiation being the least intense. The true absorption coefficients are 0 020, 0 073, and 0 21 respectively per metre of water The fourth component, with the longest wave length, could not be determined numerically

According to Klein and Nishina's formula, the wave-length of the hardest component is $0\ 63 \times 10^{-13}$ cm, whereas the complete transformation of a proton and an electron into radiation would correspond to a wave length of $1\ 313 \times 10^{-13}$ cm

Excitation Probabilities of Singlet and Triplet States

IT has long been known from experimental evidence[1] that triplet states in the spectra of two electron systems differ from the corresponding singlet states in their behaviour to electron impact The probability of excitation of a triplet level has a sharp maximum for electron energies just above the excitation potential whereas in the case of singlets the maximum probability is not sharp, and occurs at energies considerably beyond the resonance potential, also, for high velocities the triplet excitation is negligible compared with the singlet excitation The difference must lie in the fact that the triplets can only be excited from the ground state by electron exchange, and Oppenheimer[2] has shown in general how this may be approximately calculated

Using this theory and wave functions given by variation methods[3] we have calculated the probability of excitation of the 2^3P and 2^1P states of helium as a function of the velocity of the exciting electrons The curves obtained are shown in the accompanying diagram (Fig 1) and exhibit the above

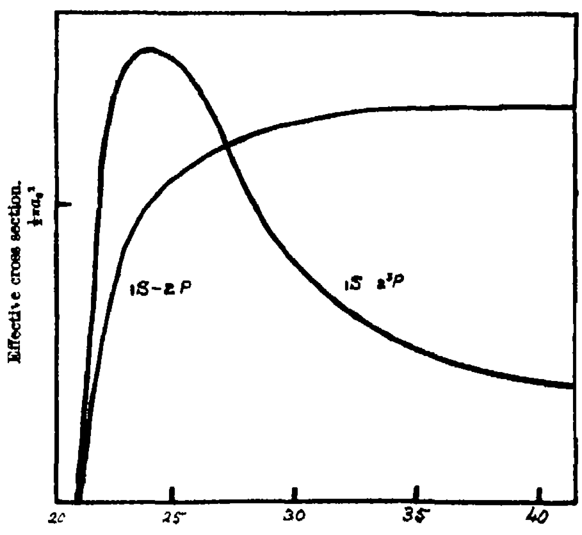

FIG 1 —Excitation probabilities of singlet and triplet P states of helium The ordinates for the singlet have been halved, to facilitate comparison

$a_0 = 0\ 53 \times 10^{-8}$ cm the radius of the first Bohr orbit of hydrogen

mentioned characteristics No high accuracy is claimed for the absolute values owing to the approximate nature of Oppenheimer's theory, but it seems clear that quantum mechanics adequately describes the phenomena

A detailed account of this work will be published

later, with calculations already in progress for other levels, including the effect of exchange on elastic scattering The probability of dissociation of hydrogen molecules by electron impact into two neutral atoms in the ground state, which is a similar process to the excitation of triplet states, is also being considered

The Crystal Structure and Polymorphism of Hydrogen Halides.

IN a previous letter to NATURE (July 19, 1930, p 97) I communicated some preliminary results upon the crystal structure of hydrogen iodide I have now repeated, with greater accuracy the X ray examination of this substance, in order to investigate the discrepancies previously observed in certain values of the lattice dimensions, and have also examined solid hydrogen chloride and bromide at different temperatures, using, for X ray examination, the same apparatus as previously described (NATURE, Mar 22, 1930, vol 125, p 457, *Rend Acc Lincei*, vol 11, p 679)

The results obtained for hydrogen chloride agree, in the main, with those of Simon and Simson (*Zeitschrift f Physik*, vol 21, p 168), with the exception that the a constant of the cubic modification, stable over 98° abs, has been found to be smaller than that obtained by them, namely, $a = 5\ 44 \pm 0\ 01$ A at the transition temperature (instead of 5 54 at 103° abs by Simon and Simson) The volume of the elementary cell is then 161×10^{-24} c c, the density, for a cell containing 4 molecules, is 1 49, which is in better agreement with the experimental density (1 47) than their calculated results

The modification of hydrogen chloride stable at lower temperature was examined by cooling the capillary of the spectrograph with liquid nitrogen The photogram taken at 85° abs shows numerous lines, of which only a certain number correspond to the tetragonal system for an axial ratio $c/a = 1\ 10$, and for one side of the base of the elementary prism $a = 5\ 27$ A Most likely this modification of hydrogen chloride possesses a lower symmetry, perhaps rhombic, with axial ratios near those belonging to the tetragonal system

Hydrogen bromide, like the chloride, is dimorphous The modification, stable at high temperature, shows at 100° abs a face centred cubic structure The side of the elementary cell is $a = 5\ 77$ A, the volume 192×10^{-24} c c, the density, for a cell of 4 molecules, 2 78

The low temperature stable modification shows tetragonal symmetry, with an axial ratio $c/a = 1\ 10$, and with a basic side $a = 5\ 55$ A, or perhaps a pseudo tetragonal structure with ratios very little different from those of a tetragonal one The volume of the cell is 188×10^{-24} c c at 90° abs

Various photograms of hydrogen iodide have been taken, cooling in succession the capillary of the spectrograph with liquid hydrogen chloride (188° abs), methane (112°), oxygen (90°), nitrogen (77°) Hydrogen iodide was prepared by the action of iodine upon red phosphorus I have succeeded in getting much better defined photograms than before They contain many lines which cannot be ascribed to iodine impurities originating from photochemical decomposition of hydrogen iodide, as I thought at first, and which cannot be arranged in a cubical structure On the other hand, following this hypothesis, some divergences could be observed between the calculated and the experimental lattice distances. I have thus come to the conclusion that hydrogen iodide does not show, as I had previously considered, a face centred cubic structure, but a face-centred tetragonal structure with an axial ratio not much differing from the cubic one As a matter of fact, all lines of the photogram can be assigned to a face-centred tetragonal structure, with an axial ratio $c/a = 1\ 08$ and a side of the elementary cell $a = 6\ 10$ A at 100° abs The volume of the cell is 245×10^{-24} c c, and the density, for a cell of 4 molecules, 3 45 (The present values do not differ much from those previously calculated for a cubic structure)

From the lattice constants of the cubic modifications of hydrogen chloride and bromide the ionic radii of chlorine and bromine can be calculated, assuming the ions to be tangential in the face centred cubic lattice the new values are somewhat higher than Goldschmidt's values calculated from the alkaline halogenides ("Geoch Verteilungsgesetze d Elem", *Norsk Vid Ak*, 7, 1926), but they are perfectly consistent, as previously pointed out by Nasini and myself (NATURE, Mar 22, p 457, June 14, p 889, 1930 *Rend Acc Lincei*, vol 11, p 1009, vol 12, p 141, 1930), with the atomic radii of the inert gases having the same number of external electrons, as the following table shows

Cl = 1 81 (Goldschmidt),	1 92 (Natta)	A = 1 92 (Simon Simson)
Br = 1 96 ,,	2 04 ,,	Kr = 2 04 (Nasini Natta)
I = 2 20 ,,	2 21 ,,	X = 2 18 (Natta Nasini)

The 2 21 value of the iodine ion is obtained from the ratio of the volumes of the elementary cells of the isomorphous modifications of hydrogen iodide and hydrogen bromide, assuming as the bromine ionic radius that calculated from the cubic modification of hydrogen bromide We might also assume for the iodine ion a non-spherical form, as has already been suspected from the structure of other iodides

I cannot agree with Simon and Simson's hypothesis as to hydrogen chloride, and I assume that hydrogen halides show ionic structure and not molecular lattices as supposed by them This is proved by the agreement observed between the ionic radii of the free hydrogen halides and those of the alkaline halides The contraction suffered by the anion in the lattice of the latter must be ascribed to polarisation forces due to the alkali cation

Bands in the Spectrum of Boron Hydride

WITH the object of obtaining band spectra due to compounds of boron, we have investigated the radiation emitted by a condensed discharge in a tube through which a stream of BCl_3 was passed Besides the atomic lines of boron, chlorine, aluminium (from the electrodes), and hydrogen (perhaps due to HCl present in the BCl_3), we found a number of widely spaced bands in the neighbourhood of 4000 A, which we ascribe to the molecule BH Photographs taken in the first order of a 21 ft concave grating showed that these bands consist of single P, Q, and R-branches, the Q branch containing a considerable number of lines, and the lines $P(0)$, $P(1)$ being missing The bands must hence be considered as a $^1\Pi \longrightarrow {}^1\Sigma$ transition, probably corresponding to the $^1\Pi \longrightarrow {}^1\Sigma$ transition observed for AlH by Eriksson and Hulthén [1] The P- and R-lines of the strongest band are accompanied for higher rotational quantum

numbers by weak satellites due to the isotopic molecule $B^{10}H$ The frequencies of the principal lines, emitted by the molecule $B^{11}H$, may be represented with good approximation by writing for the rotational terms of the $^1\Pi$ state

$$T' = \nu_0 + B'(J+\tfrac{1}{2})^2 + D'(J+\tfrac{1}{2})^4,$$

for the rotational terms of the $^1\Sigma$ state

$$T'' = B''(J+\tfrac{1}{2})^2 + D''(J+\tfrac{1}{2})^4,$$

with

$$\nu_0 = 23073\ 60, \quad B' = \begin{cases} 11\ 938, \\ 11\ 908, \end{cases} \quad D' = -0\ 00147,$$

$$B'' = 11\ 798, \quad D'' = -0\ 00114$$

The two values of B' in the upper state arise from the fact that its rotational levels consist of two components each on account of Λ doubling Their difference increases proportional to $(J+\frac{1}{2})^2$ or practically proportional to $J(J+1)$ as required by the theory for $^1\Pi$ states [2] The lines of the Q branch start from the lower, the lines of the P and R branch from the higher ones of these components From the above values of B one finds for the moments of inertia $I' = 2\ 32 \times 10^{-40}$ gm cm^2, $I'' = 2\ 35 \times 10^{-40}$ gm cm^2, for the internuclear distances $r_0' = r_0'' = 1\ 23 \times 10^{-8}$ cm Although the moment of inertia is slightly smaller in the upper state, so that one expects at first that the bands would be shaded toward the violet and that the P branch would form the head, the fourth power terms in the formulæ for the term values reverse this behaviour and cause the R branch to form a head in the neighbourhood of $J = 24$ Since the moments of inertia differ so slightly in the two states, the lines of the Q branch lie at first extremely close together and only become resolvable for $J = 18$ on our photographs The band just discussed very likely is the $0 \longrightarrow 0$ band of the system Two weaker bands of the same general appearance with origins at 4367 A and 3696 A we believe to be the $1 \longrightarrow 1$ and the $1 \longrightarrow 0$ bands Full particulars, also as regards the analysis of these weak bands, will be published elsewhere

We wish to express our thanks to Dr Kronig for many valuable suggestions during the course of this investigation

Spectra of Te IV and Te VI

FOLLOWING the identification of the doublet system of Se IV (reported in NATURE of Oct 11, 1930, p 568, and recently communicated to the Royal Society), the corresponding spectrum of tellurium, of the same chemical group, has been examined Vacuum spark spectra of the element, taken at Uppsala, in the region λ1400-λ400, have indicated the existence, among the lines of Te IV, of several pairs with separation 9222 cm^{-1}, which could be easily assigned to the configurations $5s^25p$, $5s^25d$, and $5s5p^2$ of trebly ionised tellurium

Three pairs with $\Delta\nu = 11{,}814$ cm^{-1} have also been identified as being $5^1S\ 5^3P$, 5^3P-6^3S, and 5^3P-5^3D of Te VI

Further details will be published shortly

Change of the Electric Polarisation of Ethyl Ether with Temperature.

ONE of us has recently determined the changes of the dielectric constant E and density D with temperature T (J Mazur, NATURE, **126**, 649, 1930)

Starting from these data, we have computed, with the aid of the Clausius Mossotti formula

$$P = \frac{1}{D}\frac{E-1}{E+2},$$

the values of the dielectric polarisation of ethyl ether for the interval of temperatures between $-118°$ C and $+35°$ C The results of the computation are represented on the accompanying graph (Fig 1)

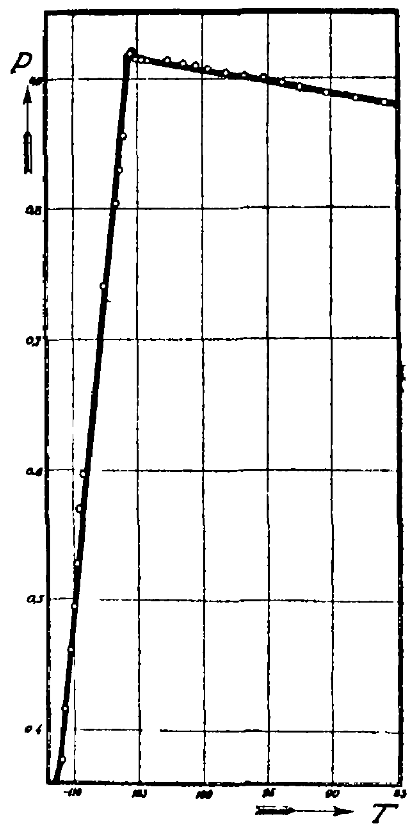

FIG 1

The value of the dielectric polarisation increases slowly with the lowering of temperature from 0 5858 at 35° C up to the maximum value 0 9209 at -105 4° C At this temperature there is a sharp decrease of the value of the polarisation

This very marked change suggests that at the transition point -105 4° C previously found by us (M Wolfke and J Mazur, NATURE, **126**, 684, 1930), the structure of the molecule of ethyl ether undergoes some modification The behaviour of ethyl ether at the point of change -105 4° C would thus differ from that of the helium (M Wolfke and W H Keesom *Comm*, Leyden, No 1, 92a) A further study of this phenomenon is being made

Species-Pairs among Insects.

ATTENTION has recently been directed to the water beetles *Deronectes depressus* F and *D elegans* Panz by F Balfour Browne in an interesting contribution to the *Scottish Naturalist* (Nov Dec 1930, pp 172 188) In a previous study (*Ann Mag Nat Hist*, Ser 9, vol 3, pp 293 308, 1919) he showed that these two species could be separated by a number of characters—size, shape, colour, tarsal claws, width of ædeagus—but that intermediates could be found which formed an unbroken series connecting the two by insensible gradations His recent paper discusses the distribution, which is of great interest In southern England, *D elegans* only occurs, in northern England and southern Scotland, both species are found, with all grades of intermediates, in northern Scotland and throughout Ireland, only *D depressus* and intermediates approximating to the *D depressus* type occur

In 1927 Georg Ochs (*Koleopt Rundschau*, Bd 13, pp 34 36) directed attention to the whirligig beetles known as *Gyrinus natator* L, and showed that two forms, separable by size, colour, shape, punctuation, and slight differences in the ædeagus, were confused under this name The true *G natator* L is found in the north eastern palæarctic region, while the other form, *G substriatus* Stephens, occurs in south west Europe At the extremes of their range both forms occur without admixture, while in northern Europe both can be found side by side The common British form is *G substriatus*, and D Sharp, who examined very large numbers, appears to have met with no other I have recently found a dark form occurring in Cambridgeshire and Scotland, which I described as *G natator* var *fowleri* (*Ent Mon Mag*, vol 66, p 74 1930) Since then, through the kindness of F H Day and H Britten, I have examined specimens of the true *G natator* L from Cumberland My specimens of *G natator* var *fowleri* form an almost perfect series connecting *G natator* L and *G substriatus* Steph

It therefore appears that we possess in *G natator substriatus* a species pair almost exactly paralleling the *D depressus elegans* pair so beautifully worked out by Balfour Browne This seems unlikely to be mere coincidence, particularly as both the northern species are characterised by melanism and pure races of the southern species occur in southern England It may be that other similar pairs exist in other groups No doubt a proper study of such species will go far towards a solution of some aspects of that difficult matter the 'species problem', and throw new light on the process of evolution, here apparently in actual progress I would therefore be glad to have further information and also material of *Gyrinus*, preferably in alcohol, from different localities, particularly Scottish, Irish, and Continental JOSEPH OMER COOPER

Curling

I HAVE read with considerable interest the letter on curling by W H Macaulay and Brig General G E Smith in NATURE of Jan 10, in which they attribute the final twist of the curling stone to regelation But surely the time has come when regelation in this connexion should be relegated to the place of a laboratory myth, and might almost disappear from elementary text books In 1921 the late Sir George Beilby produced his famous book on "Aggregation and Flow of Solids" (Macmillan and Co, Ltd) and showed that these familiar ice problems can only be explained on the theory of surface and mass flow

It is doubtful whether a really heavy man, even if he were standing on one skate only, could exert sufficient pressure to raise the temperature of the ice to anything like the amount required by the theory of regelation, while a curling stone weighs only a few pounds and presents, relative to a man on one skate, a very large surface to the ice

In curling, one is dealing with a large number of factors, but it is more or less possible to single out three which are of primary importance

The first consists of the direction of mass flow of the ice On a really cold morning, and in the absence of sun and on a carefully flooded rink, this should be more or less constant Anything like a rise in temperature caused by bright sunlight will upset the conditions considerably, and hence the interesting but somewhat disconcerting variability of the ice as the sun rises over the hills and throws its welcome rays on those who are curling, about eleven o'clock in the morning during the winter sports season in Switzerland

In the actual curling there are two main forces acting on the stone in addition to gravity These are, of course, the initial forward motion of the stone and the twist or *handle* Both of these are inducing surface flow on the ice, and the actual direction of the stone is the resultant of these two forces, one or both of which may be opposed or reinforced by the direction of mass flow of the ice and hence the very intricate nature of the problem It is easy to see that if the direction of mass flow of the ice is the opposite to that of the initial direction of the stone, as the stone slows down a considerable amount of rotation may occur, and the stone may even remain stationary but rotating

Beilby showed that the normal surface of the ice, or that due to mass flow, is entirely different from the *vitreous* surface due to surface flow, the ice composing the surface of the one being stable in the absence of friction, while the ice composing the vitreous film is only stable at temperatures far below the normal melting point of ice The conditions on the typical curling rink in Switzerland are such that the transitions of surface flow to mass flow are very rapid and, in some cases almost instantaneous

That the problem is essentially one of the resultant of mass flow and surface flow is strongly borne out by the effect of sweeping Anyone who has been on the curling rink must have noticed the almost astounding effect that can be produced by good sweeping The real effect of an expert sweeper is to induce a strong surface flow and hence a vitreous film immediately in front of the stone hence the velocity of the stone is maintained and it does not curl

Biology in Education and Human Life

IN my Henry Sidgwick Memorial Lecture (NATURE, Jan 3, 1931) I protested that 'those should be regarded as lacking education who are altogether ignorant of the nature of living things' (p 21) Mr A D Ritchie has directed my attention to a sentence of Robert Boyle's, who about two and a half centuries ago, in much more beautiful words than mine, urged similarly that it is "highly dishonourable for a reasonable soul to live in so divinely built a mansion as the body she resides in altogether unacquainted with the exquisite structure of it" A V HILL

The Monds and Chemical Industry a Study in Heredity.

"I propose to present his character and story with this object to cite him as the great example of those who do mightily yet cannot see what they are doing and who stand on the edge of doom with no vision of its approach"
—*Wolsey* HILAIRE BELLOC

"IN this world, one is too frequently approved or disapproved without being understood" This remark is passed by the Japanese professor of art, Yukio Yashiro, in the preface to the new edition of his opulent work on "Sandro Boticelli", in discussing criticisms aimed at his book Is it possible to understand any complex personality to the point of being able to "approve" his actions, by analysing them to their origin? Prove, German *prüfen*, is a very difficult verb to apply, at least in English, in German, it is without ambiguity

Some day, perhaps, biography will be written almost in terms of structural chemistry and the doctrine of descent stated in terms of the permutations and combinations effected between genes then, types, structural units, will be dissected out It is fast becoming clear that even the most complex of natural molecular units are but repetitionals that they are built up of simple parts frequently repeated The candle is a fit emblem of its substance as it may be made of any length, burnt to any shortness, to the mind's eye, it is the like of the Roman *Fasces*, in contexture When, at last, we see ourselves as chemists shall see us, the most wonderful imprint of pattern will be displayed upon our skins Maybe the analysis will not be possible before 'Jeansery' is at its last gasp and we are about to dissolve into radiation Still, suspicions of structure are already held by some of us

I merely wish to claim, in all modesty, that biography should be the recognised province of the structural chemist he alone can appreciate the complete interdependence of character and structure The supreme interest of chemistry comes from the fact, that it is the study of character as affected by structure Our senses seem to be but distortions of structure and electrical ripples—purely physical 'emotions' Witness the Poulsen phonograph, in which a steel tape is drawn across the magnetic field of the telephone returning the tape against the way it came, we have speech reproduced The tape hears and remembers what it hears, can tell what it has heard it all but lives! It is so human that it also forgets We cannot doubt that the molecules of the metal are displaced when magnetically spoken at, that they remember by retaining the new positions imparted to them, that speech is the molecular click as they revert to their original positions Seeing that 'wireless' can hit us as it does, there is no difficulty in understanding that we cannot but respond to every impression from outside

We need to be far more observant of hereditary character The Mond family seems to me to be specially deserving of study in this connexion Seldom has the biographer had the opportunity I have had of observing both father and son throughout their whole career of public activity I first met Ludwig Mond when his son Alfred was only three or four years old, in the early 'seventies. The parents were cousins, their two sons, Robert and Alfred, have always seemed to me to be near hybrids but with a clear bias from the mother The father was a man of very strong and determined character, almost rough originally, the mother, a woman of peculiar sweetness and sanity of outlook

Alfred Mond was born when a touch of sulphur was still lingering in the air, under a just ascending star, a true nova of the first magnitude in industrial progress Growing up in an environment of strongly alkaline pH he was to develop throughout the p gamut, ever progressing, first as politician of changing hue, from a radical bright red to a mild conservative blue, then as 'company combiner', until at last he became not merely leader as an industrial magnate but an industrial statesman—the first of his kind No more interesting man has trodden the stage of public life during his period In heredity and environment, he was subject to exceptional influences probably he had no peer, at least in his later days, when again the p's come in He was a peculiar being, maybe the forerunner of a new type the politician with intelligence, fully alive to the value and use of knowledge, even in the affairs of government as far from the demagogue as he possibly could be hence possibly the antagonism between him and Mr Lloyd George let us hope the last representative of an expiring crude and unscientific civilisation

Ludwig Mond, his father, came to England fully prepared, both by German education and Dutch experience of the alkali trade, for the work he undertook—aflame with the pioneering spirit and full of masterful energy He brought with him a process for the recovery of sulphur from alkali waste, then a nuisance as well as a by product This did not carry him far Hearing of Ernest Solvay's invention of an improved and novel process of making soda from salt, without sulphuric acid, he went over to Belgium and was just in advance of another claimant, Walter Weldon, in securing the English rights to work the invention As Mrs Mond told me more than once, he was ambitious, even in those early days, to play the part of the constructive pioneer, to be original, not merely to make money Originality, we have been told, consists in thinking for yourself, not merely in being different from others Ludwig Mond, in this respect, was most original He also knew his own limitations—that 'business' was not his forte so he sought out the ablest business man within his reach and found him in (Sir) John Brunner They were a perfect pair—one looked after the pounds in the works, the other after the pence in the office Mond secured a mere sketch from Solvay a vast amount of detailed work was necessary to bring the process to perfection it was full of difficult engineering minutiæ Taking off his coat, spanner in hand, he himself tightened up each bolt until the last leak of ammonia was overcome The ammonia-soda process was thus

quickly established, almost in its full perfection Mond was soon seen to be a destroying angel on Tyneside as the firm rapidly came to the fore The old Le Blanc process was mainly kept alive for its by-products

Ludwig Mond left Germany years before the time when the laboratory became a fashionable and necessary adjunct to the works—the source of advance, not merely a control station He also never followed the German system of giving members of the staff an interest in improvements or discoveries they might make Perhaps on this account the works remained an ammonia-soda works Still, his own mind was at work, seeking fresh fields to conquer Thinking in terms of ammonia, he was led, in the middle 'eighties, to take up the gasification of coal, largely with the object of recovering its nitrogen as ammonia He established large works at Dudley Port, from which producer-gas was supplied to the surrounding district The enterprise has not been the economic success that was expected, the more as conditions have changed to its disfavour—especially, of late, owing to the rise in the price of coal and the introduction of synthetic ammonia, which has much lowered the value of scrubbed ammonia It is strange how little success has attended all tampering with coal—except at the hands of the gas companies, who have known how to roast it hard all low temperature attempts have been economic failures and probably will remain so, at least until effective means of cleaning coal from dirt be devised Still, Mond's experiment has been of remarkable interest in many ways, as it has involved producing and carrying vast quantities of gas long distances at controlled rates, without use of holders The control secured is altogether surprising, on account of the scale of working Also, a hive of 'small industries' has been established

Had not Mond made what to me always seemed to be a blunder by burning coal to a *weak* gas, thinking its nitrogen to be of sufficient economic value to be worth recovery, although this involved the sacrifice of the tar, I believe he would have taken up the low temperature distillation of coal himself I had brought the subject before the Iron and Steel Institute in 1885 and had almost persuaded him to undertake an intensive study of coal, when suddenly he became over-excited by thoughts of ammonia Had he done so, he would have carried out the inquiry scientifically and thoroughly thirty years ago, probably, we should have known where we were, and the public would never have been gulled into believing in the commercial possibility of oil from our coal Undoubtedly, a vein of idealism now began to be apparent in him He had little real feeling for coal as a substance, not being an organic chemist, nor had he specially directed his attention to fuel problems, although ever mindful of the need of preventing waste of energy Probably, he went out of his depth

At this time Mond's ever active mind embarked on a fresh quest Mindful of the great loss of energy involved in the use of solid fuel, he sought to develop the Grove hydrogen-oxygen, sulphuric acid, platinum, gas cell again perhaps a stroke of idealism For this purpose, he needed hydrogen in large quantity The only economic source was 'water-gas', the mixture of hydrogen and carbonic oxide produced by passing steam over heated carbon (anthracite) It was necessary to remove the carbonic oxide, a virulent poison to platinum He used a known method, which involved passing the mixture of gases over heated nickel In experiments carried out in his laboratory, in St John's Wood, his assistant, Dr Quincke, to prevent the passage of the poisonous carbonic oxide into the air, put the end of the escape tube from the apparatus into the air hole at the base of a Bunsen burner He noticed that the gas burnt with a smoky flame—evidently there was some volatile product Mond not only at once followed up this indication to the quick discovery of nickel carbonyl, $Ni(CO)_4$ finding this was easily resolved into nickel and carbonic oxide by heat, he forthwith developed a continuous reversible process for the manufacture of nickel on the large scale He was greatly assisted by Dr Langer, one of Victor Meyer's most able pupils The achievement is without precedent in the history of scientific manufacturing enterprise, in virtue of its originality, the rapidity with which it was conceived and the intrepidity with which it was executed

Ludwig Mond, therefore, was the founder of at least three industrial enterprises—two of them are great and highly successful and likely to be permanent He knew his subject he had practical chemistry in his bones, if ever man had Ever a thinker and worker, a man of action, never a man of words—he wrote no letters apart from business —he was highly cultured a good linguist, an art patron, himself a good judge From boyhood up, Mrs Mond had led him in literature and art She was an idealist of the first water, saturated with Goethe Their daily life was perfect

The son's career was very different He had not the advantage of a serious German education At school and university, he will not have been overtaught he was never spurred to special effort, as his father was, in order to make his way From an early age, brought up in a specially cultured society, using his own great innate ability, he himself became a man of considerable culture He read law but never entered into practice So far as I know, he had merely gathered impressions of natural science and had no affinities to it, differing in this respect from his elder brother, who has considerable knowledge of physical science and experimental proclivities

The son of parents situated as his were had no cause to exert himself He gradually became the politician, perhaps, too strong a radical to please his father Here probably he was greatly influenced by the late Sir John Brunner, an ardent politician In the House of Commons, a speaker of weight, he was so clear-headed, so well informed, so obviously a thinker of unusual breadth and sanity, that he soon acquired distinction In political office, he showed real administrative ability That he had a scientific mind was shown by his gradual

change in political outlook and his change of party. Of course, for party purposes, a man must resist the influence of intelligence and stick to his party; but it is only from this point of view that change of party is to be deprecated; actually, it is proof of strength and individuality—in no way discreditable.

In a measure, his translation to the Upper House, in 1928, probably in no way satisfied his ambition and was a disappointment, marking as it did the close of his political career. He had aspired to the highest office, beyond doubt, but pronounced idiosyncrasies of manner were against him: he was outwardly 'too foreign' to be acceptable. To satisfy his aspiration, in his later years, he devoted himself to industrial rather than to political statesmanship. The spirit of idealism, which I have spoken of as actuating the father, became greatly operative in the son. He showed himself to be gifted with a co-ordinating mind, whilst his father had been constructive. He entered into a discussion of the problems of labour and in the interests of 'rationalisation'—to use the fashionable word of the day—effected two great industrial combines. Whatever assistance he may have had, there is no doubt that his was the guiding spirit, his the driving force. To come back to chemistry, while the father was a true chemist, a highly original worker, who really made things, the son was like the modern physical chemist, who is more or less a visionary and a speculator in other people's works, not a worker himself. Apparently, the one cannot be the other. Some of us contend that the physical chemist does not know enough chemistry to justify the certainty of his opinions. It is a question whether Alfred Mond knew enough to deal with issues and problems of the complexity and magnitude of those he undertook. Although scientific in his outlook, a systematic user of knowledge, he knew nothing of experimental and physical science and cannot have had any real feeling for the industries with which he was connected.

In effigy to-day he commands an Imperial position in Chemical Industries—his father on his right hand. By a strange turn in the wheel of fortune, he was led to develop, on a colossal scale, the manufacture of ammonia from atmospheric nitrogen by the Haber Bosch process, so taking a step commercially antagonistic to his father's perhaps most favoured enterprise: ruinous also to the Chile nitrate industry. It may be that one good turn deserves another: industrial progress, so-called, too often seems to involve the supercession of earlier workers. The grave economic, political issue of the present universal industrial rush to our atmosphere, however, has yet to be apparent. To make the inert active is always dangerous, if not an impiety; it may well be a jump from frying-pan into a burning fiery furnace of soil destruction.

Father and son probably could never have exchanged places: they were different natures. Ludwig Mond kept pretty well within the limits of his abilities and sought competent assistance when going outside them: to decide to what extent the son was Napoleonic and overstepped his, will not be easy. One thing is certain, that like his father before him, he gave his full strength to whatever service he undertook. Opinions greatly differ as to the wisdom of his action—as to the competency of a system such as he sought to develop. On account of the growing gravity of the industrial situation, the absolute need of completely scientific management—in other words, of complete understanding—a full inquiry into the problem of control should be undertaken with all possible care and without delay. The matter is already engaging attention abroad and such discussion is therefore of immediate national importance to us. It cannot be undertaken by men of affairs alone—they have not the necessary breadth of knowledge.

Much is said of academic research as the mainstay of industry and industry is being called upon to give support to the work. At the moment, there is great waste of energy and of funds, both national and private, on account of lack of co-ordination and clear cut views as to the purpose of the work—particularly because of the lack of competent supervision. The great need in industry of full inquiry into the efficiency of the methods followed in its own management and conduct has yet to be recognised: in such direction, industrial research is imperative.

HENRY E. ARMSTRONG.

Southern Whales and Whaling.

THE Discovery Committee appointed in 1923 as a result of the findings of the Interdepartmental Committee on Research and Development in the Dependencies of the Falkland Islands is now issuing, under the general heading of "Discovery Reports",* a series of reports by the Committee's scientific staff and others on the investigations being carried out in the southern hemisphere—mainly regarding the scientific aspect of whales and the whaling industry. As in other recent expeditions, the reports are not published in any definite sequence of subject, but as the different stages of the work are completed. The advantages of this procedure are obvious.

The principal industry of the Falkland Islands is whaling, and, since the inception of commercial operations in 1904, there has been a rapid rise in the success of the industry. The history of whaling operations in other parts of the world has acted as a powerful stimulant, both to the administrative controllers of the Dependencies and to scientific experts, to gauge the effects of excessive slaughtering of

whales and, if necessary, to devise a system of regulation to maintain the stock It is not feared that the whales will be actually exterminated—because the industry must fail long before the whales are reduced to the point of extinction—but that the industry will collapse and the valuable supply of oil will be lost Any restrictive legislation, whether national or international, must be based on the findings of scientific research The prevention of waste at shore stations under the jurisdiction of the Government is a matter of routine, but the protection of the stock of whales calls for more knowledge than the scanty data at command can supply It is, therefore, the object of these investigations to achieve more definite and increased knowledge of whales on which to base methods of conservation, and to Mr Darnley and Sir Sidney Harmer credit is largely due for laying the foundations of this whaling research

Vol 1, which was published during the early part of the past year, contains the results of part of the work undertaken by the staff during the years 1925–1927, and consists of six parts, with a foreword by Mr E R Darnley, chairman of the Committee The Station List which occupies the first part is more or less stereotyped, but the tabulation, opposite each station, of the hydrological observations, including hydrogen ion concentration, oxygen and phosphate contents of the sea water at different strata, is a distinct advantage

In the second part, the Director of Research, Dr Stanley Kemp, gives a brief outline of the aims and objects of the investigations, stating that " the main object of the work is to obtain further information on whales and on the factors which influence them " This entails studies of the whales themselves and of their environment Work at a shore station was considered essential and a marine laboratory was established at South Georgia, where the whales landed in the course of commercial operations were examined by the resident staff with the view of determining their specific identity and their relationship with similar types captured in other areas Concurrently with the collection of statistics for racial studies, investigations were undertaken on the anatomy of the whale to elucidate the fundamental points in the life history of the species As commercial whaling more or less ceases during the antarctic winter, the observations at the laboratory at South Georgia do not cover the full reproductive cycle, so that a transference of the staff during the southern winter was made to South African waters, where similar work was continued on the whales landed at Saldanha Bay The study of the environment of whales could only be attacked by observations at sea, and it was considered necessary to have two ships to cover the enormous area in which observations would have to be made to cope with profitable lines of research The *Discovery*, Capt Scott's famous ship, purchased and specially refitted, was commissioned in October 1925, as the larger ship, for the major part of the oceanographical work, while the smaller *William Scoresby*, built on the lines of a whale catcher, was designed for the pursuit of whales, with the primary object of shooting numbered discs into them in an attempt to get actual data as to their migrations. The general programme of investigation follows very closely on the lines adopted for the study of commercial food fishes by the International Council for the Exploration of Northern Seas

In the same report, the equipment of the ships is discussed by Dr Kemp and Mr (now Prof) A C Hardy The structural alterations in the *Discovery* and the fittings for the working of the most modern scientific apparatus are described in detail (see also NATURE, June 20, 1925, p 950) There are numerous diagrams and photographs illustrating the various points The *William Scoresby* was built to the specifications of the Committee on the lines of a whale-catcher and was further adapted for commercial trawling Apparently she has turned out to be very efficient as a sea going ship and trawler but only moderately successful, so far as the experiments have gone, for shooting numbered discs into live whales—probably because of the ship's larger size, slower handling, and increased noise in comparison with the usual whale catcher The type of mark, however, its size, and the method of shooting, from a rifle which is effective only at a very short range, seem to affect the success of the operations Several methods of marking have been and are being tried, mostly by Norwegians, but there appears to have been a lack of success in all of them The problem is most difficult and its solution is absolutely essential for the success of the investigations, but no doubt every effort is being made to obtain successful results In the same report the construction and fittings of the shore laboratory at Grytviken, South Georgia, are described by N A Mackintosh, who was in charge of this station Here the methods employed for counteracting intense cold and high winds form an interesting adjunct

A further part is devoted to the seals of South Georgia and is by L H Matthews Attention is directed chiefly to a study of the natural history of the elephant seal, which has been the object of pursuit for about two centuries on account of its valuable commercial properties, and has undergone considerable fluctuations in abundance of the stock The elephant seal is polygamous, as shown conclusively, if such proof were needed, by the photograph of a harem taken purposely during the *Endurance* Expedition in November 1914 and reproduced in this publication Apart from this factor, which supports scientific selection in slaughtering, the sealing industry has been under efficient Government legislation since 1910, when special sanctuaries were set aside for the preservation of the species Since the beginning of the century the southern fur seal has been observed on rare occasions in the Dependencies of the Falkland Islands, and the problem of re establishing the species in these subantarctic islands, with the view of scientific farming on the lines of the successful experiments by the United States Government at the Pribylof Islands, has been receiving attention

The section by Messrs Mackintosh and Wheeler, on southern blue and fin whales, with appendices by Mr Clowes, is a compendious report which

occupies about half the volume and is the result of the work on the whales landed from 1925 to 1927 at the shore stations—Grytviken, in South Georgia, and Saldanha Bay, South Africa A considerable part of it is taken up with descriptions of the external characters of these two species and with tables of measurements of body proportions, with the view of establishing the specific characters of southern whales and to define the limits of variation This is an essential part of the investigations, as information on the specific, sub specific, or racial relationships with similar whales in other areas is of fundamental and far-reaching importance From the treatment of their data, the authors are convinced that there are close resemblances between the whales of South Georgia and South Africa, and that there are no definite grounds for sub specific or racial distinctions Comparison between the whales of the northern and southern hemispheres has not so far been attempted, at least on a large scale, but the data which are still being collected will, no doubt, be utilised for fuller statistical treatment in the near future

Examination of the stomach contents formed a routine part of the programme The results were interesting, in so much as all the whales (excluding the sperm) were found to be feeding on Crustacea—and chiefly, if not exclusively, on Euphausiæ, *E superba* at South Georgia and *E recurva* at South Africa This is an interesting and important point, which no doubt will be supplemented by observations from other southern areas So far as the fin whale is concerned, this species in the northern hemisphere is known to be a mixed feeder and to subsist largely on fish, but it is considered to be solely a plankton feeder in the south

Routine measurements of the thickness of blubber were also made with the view of establishing any seasonal increase or decrease and specifying its relation to the food supply Thickness of blubber has a definite bearing on oil production, but, apart from seasonal variations, information is desired on other points, such as thickness in proportion to length of whale, involving a study of physical maturity, and in females, the conditions during pregnancy and lactation In pregnant females the blubber is abnormally thick, but in whales generally there is a relative increase in thickness of the blubber with increasing whale length Whales as a rule were found to be fatter at the end of the South Georgia season, while the thickness decreased in South African waters

The anatomy and physiology of the reproductive organs have formed an integral part of the researches, and much good fundamental work has been done on the ovaries, mammary glands, and testes The evidence available from these observations has been used in the interpretation of the breeding habits and growth of whales, but information from other sources, such as the occurrence of fœtuses, the seasonal movements and habits of whales, has been utilised in piecing together the life history and reproductive cycle. The conclusions drawn from the investigations rest ultimately on breeding and feeding migrations, which in the present state of our knowledge are more or less assumed from circumstantial evidence to be north and south, but these deductions would be enormously enhanced in value if supported by direct evidence through the capture of even a few marked whales

Apart from this apparent weakness, which is largely due to the nature of the work on whales caught commercially, the authors have made good use of the data at their command and have given an acceptable estimate of several fundamental points on which accurate diagnoses are essential Thus, they have defined the mean length of sexual maturity for—

Blue Whales,	Female,	at 23 7	metres	(77 ft 9 in)	
,,	Male,	,, 22 6	,,	(74 ,, 2 ,,)	
Fin ,,	Female,	,, 20 0	,,	(65 ,, 7 ,,)	
,, ,,	Male,	,, 19 5	,,	(63 ,, 8 ,,)	

The pairing season takes place principally from May to August, with a maximum in June to July for both these species, but, as stated, the results indicate, at least for the fin whale, a protracted period over seven or eight months The authors are convinced that whales are polyœstrous, and that if impregnation be missed during any period of ripening of an ovum, there are traces of this occurrence in the ovaries as corpora lutea of ‘ ovulation ’ The frequency of this feature is unknown, but it does not strengthen claims to a breeding concentration and complicates the estimation of age by reading of the number of old ovarian scars The length of the period of gestation has been estimated at a little more than ten months for blue whales and eleven and a half months for fin whales, with possible variations according to the time of impregnation This conclusion has been drawn largely from an examination of the fœtuses obtained during the investigations and from the records of the smallest calves, which latter were extremely few From the same evidence the season of parturition was defined and the period of birth of the calves was stated as mostly April and May for blue whales and June and July for fin whales The accuracy of the determinations, however, depends largely on the question of the representative nature of the material examined

The length at birth has also been estimated in a general way and probable estimates have been given as 7 0 metres (23 ft) for blue whales and 6 5 m (21 ft 3 in) for fin whales The average length at which weaning takes place has been more difficult to determine, as the data on which the estimate has been made are rather scanty, but the rate of growth of the calf during the nursing period has been approximated with the help of data supplied to the British Museum by the whaling companies at South Georgia and at South Africa The duration of the nursing period has been put at about seven months for blue whales, and for the fin whales, on slightly less representative material, at six months During this period the astonishing result has emerged that the blue whale calf more than doubles its length, while the rate of growth of the fin whale calf is also rapid but not quite so considerable The subsequent growth of the adolescent whale to sexual maturity again rests a good deal on conjecture, but

there seems sufficient justification for the authors' interpretation of the available statistics that sexual maturity is reached at the end of the second year, at lengths already stated for each species No definite method for determining the age of whales, beyond the early stages, has emerged, though various studies have been made in this direction, but these have not advanced beyond the stage of fixing that the whale is either an old or a young one, for example, by the number of old scars on the skin, the condition of the vertebral epiphyses, and the number of old corpora lutea

The application of the results obtained to economic conditions is discussed at some length, but as this necessitates a thorough understanding of the whole stock of whales, the question will have to be considered from all points of view The arguments put forward by the authors refer to the particular areas in which the investigations were made, and rest largely on the assumption that there is little discrimination in the killing of the whales in any particular area, and that the nature and composition of the catches are likely to be fairly representative of the whale population The problem of fluctuations in the number and condition of whales requires a lengthy series of observations, but several interesting points are touched upon in the present report which, with a fuller knowledge, may prove to be of great importance Much is made of the concentration of whales in the area of the Falkland Islands, and some of the causes for this concentration are given considerable prominence, but there are a few million square miles of sea round the antarctic barrier still unexplored, and it may well be that other features will emerge which will call for intensive study In the history of whaling operations in the northern hemisphere, it has been impressed on us that the *locus operandi* has shifted from one locality to another, and that in each case the killing off of the whales almost to extinction in any particular region has not been followed by a return to the region of the same type of whales in numbers sufficient to resuscitate the industry This is, meantime, an unexplainable point, but one that requires attention

The fifth part is a purely scientific report by Dr H A Baylis and deals with the first consignment of material belonging to the parasitic Nematoda and Acanthocephala collected from whales, seals, and fishes Five species of Nematoda and three of Acanthocephala are described as new to science These are interesting from the point of view of the distribution of their hosts

Another section by Mr L H Matthews is on the birds of South Georgia Thirty one species are listed as having been observed at the island both by himself and by previous observers The text is in the form of brief notes on the species, except in a few cases, for example, the Albatrosses, where the breeding habits are described from the writer's original observations In most cases a popular name is given to the species, but one misses familiar terms like Night Hawk for the Cape Hen, Paddy for the Sheathbill, Nellie for the Giant Petrel, and Johnny for the Gentoo Penguin Nineteen species were observed nesting, while other six are quoted from previous observers as breeding on the island Fregetta is recorded as being observed only by the Transit of Venus Expedition at Royal Bay, but the scientific members of the *Endurance* Expedition observed a pair of these birds at close range at Larsen Harbour in November 1914 The report opens with a curious mistake as to Shackleton's itinerary on the famous boat journey in April and May 1916 from Elephant Island, South Shetlands, erroneously stated here as South Orkneys, which, by the way, has also been overlooked in the list of corrigenda There are twelve plates (three in colour) attached to the report, and many of the figures are exceedingly good and most useful

The New Zealand Earthquake of Feb 3

By Dr C Davison

OUR knowledge of New Zealand earthquakes extends over little more than a hundred years Since 1814, when missionaries first landed in the islands, there have been four great earthquakes—in 1826, 1848, 1855, and 1929—but none of these, unless it be the earthquake of 1855, can be compared with the shock that on Feb 3 brought ruin to Napier and other towns in the North Island Certainly none has been so destructive of life On June 17, 1929, 17 persons were killed during the Murchison earthquake, in all previous earthquakes since 1848, not more than seven During the shock of last week, at least 140 lives were lost, and the number may be increased when the ruins of the larger buildings have been searched

The earthquake occurred at 10 48 A M and lasted for about two minutes The principal towns damaged are Napier and Hastings Napier lies on the shore of Hawke Bay, and the houses that suffered most are those in the business quarter, built for the most part on land reclaimed from the sea Hastings is an inland town about 12 miles south south-west of Napier The other places at which buildings are damaged or lives have been lost lie within or near a band about 45 miles long and 12 or 15 miles wide running south south west from Napier or parallel to the coast line to Waipukurau It is in the neighbourhood of Napier, however, that the material damage is greatest Railway lines there are buckled, roads are fissured, and many landslips have occurred, especially to the north of the town

The earthquake was recorded at Kew Observatory at 11 h 6 m 52 s, P M (G M T) on Feb 2, the amplitudes of the movements were about twice those caused by the earthquake of June 17, 1929, and the total duration of the disturbance was about four hours

One of the most interesting features of the earthquake is the rise of the land about Napier

The pool in the harbour known as the Iron Pot, where fishing boats and small steamers hitherto lay, is now dry land According to the report of the Governor-General, the bed of the harbour has been raised in places by 18 feet It seems clear that the rise of the land was not abrupt, for steamers left the harbour and proceeded to sea "on account of the anchorage shallowing rapidly"

For many years, slight earthquakes have been frequent in the Napier district In the list of New Zealand earthquakes from 1848 to 1890 drawn up by the late Mr G Hogben, at least 27 earthquakes had their origins in this zone

Though the stronger earthquakes of New Zealand can scarcely be ranked with the greatest of some other lands, they have all been accompanied by notable displacements of the earth's crust In 1826, a cove in the South Island about 80 miles north of Dusky Bay was converted from a safe anchorage for sealing vessels into dry land The earthquakes of 1848 visited the northern part of the South Island A great rent was then formed in the mountain chain running south south west from Cloudy Bay, and was traced for a distance of 60 miles During the Wellington earthquake of 1855, a tract of land at the southern end of the North Island measuring 4600 square miles was uplifted from one to nine feet The fault along which the greatest movement occurred runs along the eastern flank of the Remutaka range, and the nearly vertical scarp was traced for a distance of about 90 miles Lastly, with the earthquake of 1929, which occurred in the north west portion of the South Island, the ground on the east side of the White Creek fault was shown, by the renewed levelling of the district, to have risen at one point by 16 ft 1 in

The investigation of the recent earthquake by the competent seismologists of New Zealand and the re levelling of its central area can scarcely fail to add greatly to our knowledge One of the most interesting points to be determined is the connexion of the earthquake with the fault or system of faults that was in action in 1855, for though 30 miles or more to the north north east of the end of the fault scarp of that year, the meizoseismal area seems to lie along, or not far from, its line of continuation

Obituary

Mr A B Basset, F R S

Alfred Barnard Basset was born on July 25, 1854 He was educated at Trinity College, Cambridge, and graduated in 1877 as 13th wrangler, a position which could scarcely have represented his real mathematical attainments He was called to the Bar at Lincoln's Inn in 1879, but not being under the necessity of adopting a profession, he soon abandoned the law, and, apart from the duties of his private station, devoted himself mainly to mathematical research

From 1883 onwards Basset produced a succession of papers on applied mathematics, mainly on subjects suggested by current discussions The 'classical' hydrodynamics had at that time a great fascination for a number of rising mathematicians, and Basset's own contributions in this kind to the *Proceedings* of the Cambridge Philosophical Society, the London Mathematical Society, and the *Philosophical Transactions* were of distinct merit Among the numerous subjects which he treated we may mention the equilibrium of revolving fluids, and the theorems of Dirichlet and Dedekind, the interest in which had been revived by Bryan, Greenhill, and Love At a later stage he attacked the theory of elastic plates and shells, which was then a matter of controversy, and was led to recognise independently the true explanation of a rather serious difficulty Mention should also be made of his work on viscosity, and in particular on Boussinesq's problem of the variable slow motion of a sphere in a viscous fluid These are only a few items out of the long list which appears in the Royal Society's catalogue

Basset's work was distinguished throughout by a remarkable command of analytical methods As an example, it may be noted that he was an expert in the use of Bessel functions, and discovered new results in this connexion, at a time when the theory was only beginning to be familiar to English applied mathematicians He was elected a fellow of the Royal Society in 1889, and was vice president of the Mathematical Society in 1892-93

Basset was also the author of several able treatises A work on hydrodynamics, in which he incorporated much of his original work, was published in 1888, and did much to promote the interest in the subject This was followed in 1892 by a treatise on physical optics, another of his favourite subjects, to which he devoted immense pains, but which scarcely met with the recognition which it undoubtedly deserved

At a later period, Basset turned his attention to pure mathematics, and produced two text-books, on cubic and quartic curves, and on solid geometry But his interest in scientific matters, and his relations with mathematical contemporaries, seem gradually to have faded, partly no doubt owing to failing health, and he lived in great retirement at his seat in Berkshire He died on Dec 5, at the age of seventy six years H L

Dr F M Turner

Dr F M Turner died unexpectedly on Jan 17 at the age of sixty-four years, after a surgical operation Educated at Cambridge and Guy's Hospital, he was for thirty-four years the loved and respected superintendent of the South-Eastern Fever Hospital at New Cross He was an acute student of infectious diseases, and published notable work on return cases of scarlet fever in 1906 and on the relation between vaccination and smallpox in *Biometrika* in 1906 and 1907

Dr Turner was a man of insatiable curiosity and had wide interests outside his immediate professional concerns, especially in fresh water biology and the keeping of aquaria, in which he had a happy

knack He read widely and always maintained a keen interest in fresh developments of biology He took a large part in the investigation of the inheritance of sinistrality in *Limnæa peregra* with Boycott, Diver, and Garstang, recently published in the *Phil Trans*, and incidentally made a number of valuable measurements of the factors which influence the rate of growth of water snails 'Semper's law' particularly attracted him, and he succeeded in showing fairly conclusively that the larger size of individuals reared in larger volumes of water is due to the greater supply of food He also made a number of original observations on the kinds of algæ actually eaten by snails, and of their preferences and dislikes for different species Some of his results are published in the *Naturalist* (p 231, 1926) and the *Essex Naturalist* (p 48, 1927), but many of his problems were waiting for the further experiments which he had planned to make when he retired this next summer

WE regret to announce the following deaths

Mr J D H Dickson, senior fellow of Peterhouse and author of numerous papers on thermodynamics and thermoelectricity, on Feb 6, aged eighty one years

Mr D T Jones, C B E, chairman of the Fishery Board for Scotland, on Feb 4, aged sixty five years

Dr C Krumwiede, professor of hygiene and bacteriology at New York University, assistant director of the research laboratory of the Health Department of New York and past president of the Society of American Bacteriologists, on Dec 28, aged fifty one years

Dr Albert Schammelhout, secretary of the International Pharmaceutical Federation and an honorary member of the Pharmaceutical Society of Great Britain, on Jan 20, aged sixty years

News and Views.

EARLY this year we had the pleasure of offering congratulations on behalf of scientific workers generally to Sir Ernest Rutherford on the barony conferred on him by H M the King, announced in the New Year's Honours List (NATURE, Jan 10, p 65) A further proof of the world wide recognition of his brilliant achievements is the award, which we are glad to announce, of the Echegaray Medal of the Royal Academy of Sciences of Madrid This medal was founded by the Academy in honour of Señor D José Echegaray, its president from 1901 until 1916, and is awarded triennially to any person, Spaniard or foreigner, who shall, in the opinion of the Academy, have distinguished himself to an eminent degree in one or other of the branches of science for the promotion of which the Academy exists Previous recipients of the medal are Señor José Echegaray (1907), Señor Eduardo Saavedra (1910), Prince Albert I of Monaco (1913), Señor Leonardo Torres Quevedo (1916), Prof Svante Arrhenius (1919), Prof Santiago Ramón y Cajal (1922)

ON Feb 15 occurs the centenary of the death of the famous mechanician and engineer, Henry Maudslay, who was not only the founder of one of the most historic engineering firms of London but also was the originator of important advances in machine tools and engine construction He was the first to construct screw cutting lathes in which the slide rest is moved along the bed by means of a leading screw driven by change wheels, and it was from his interchangeable system of screw threads that Whitworth afterwards developed the well known Whitworth system Born in Woolwich in 1771, the son of a soldier who had become a carpenter in Woolwich Arsenal, Maudslay began work in the Arsenal at twelve years of age and by eighteen had acquired such extraordinary mechanical skill that Bramah employed him on the construction of his locks Later on, at the age of twenty six, Maudslay set up in business for himself in Wells Street, and in 1810 founded the works in the Westminster Bridge Road where, for nearly a century, marine engines were constructed for the Navy He was the maker of the famous block making machinery devised by Brunel for Portsmouth Dockyard And among his workmen were Clements, who afterwards constructed Babbage's calculating machine, Nasmyth, the inventor of the steam hammer, and Whitworth Into all his work, Maudslay introduced mathematical accuracy, while his constructions were all known for their beauty of proportion The business he founded was carried on until 1905 On his death, Maudslay, at his own desire, was buried in Woolwich churchyard, where a monument recalls his merits as an engineer and a man

THE Royal Commission on Transport, in its final report on the co ordination and development of transport in Great Britain (see also p 225), considers that of the two main causes of the present difficulties of railways, the long continued depression in trade, especially in the 'heavy' industries, is the more important, though road competition will be a more permanent adverse factor To meet such competition, a thorough overhauling of railway schedules, with speeding up of services and improved conveniences, including the removal of irritating conditions, revision of fares, and increased seating accommodation on main line trains, are recommended In regard to grouping under the Railways Act, the report recommends that each company should confine its attention to the needs of its particular area, that joint lines should be merged and the traffic pooled at points served by two or more railways Electrification of all suburban services where there is intensive passenger traffic, the closing of little used and unremunerative branch lines, and progress in the use of larger waggons and of containers are other recommendations In regard to road transport, expenditure on by pass roads but not on new arterial roads is recommended, and the activities of the Ministry of Transport should be concentrated on the complete reconstruction of many existing roads, the widening of roads, improvement of road junctions and lines of sight, strengthening of weak bridges, freeing of toll roads and bridges, and the progressive reconstruction of built up areas

THE members of the Royal Commission on Transport are satisfied that users of motor vehicles are in general fairly taxed, but that the ratepayers' burden in respect of roads is too great, they recommend that no proceeds of taxation from motor vehicles should be diverted from the Road Fund, but that the present proportion between ratepayers and motorist should be reversed The diversion of heavy goods traffic from the railways to the roads should be discouraged, steel tyres abolished, and pneumatic tyres used on all motor vehicles The report recommends that no additional tramways should be constructed, and, without laying down a definite time limit, that they should gradually be replaced by other forms of transport Certain canals are considered as still possessing real value as a means of transport, but they require rationalisation and development, although there is no territory where the construction of a new canal would be regarded as a serious proposition A number of the smaller ports have been allowed to fall into a state of decay, and the first step to be taken towards assisting coastwise shipping is the improvement of the ports used by coasting vessels In future road construction programmes, the requirements of harbour areas should receive a prominent place The Commissioners are of the opinion that, in principle, it is undesirable that one form of transport should own docks and harbours to which access by other means of transport is required A public trust is considered the best kind of authority to own docks and harbours, although transfer of the majority of railway owned docks and harbours is not recommended In regard to co ordination, the appointment of a small permanent advisory council on transport, to study transport problems both generally and in particular areas, and to advise the Ministry on action which might be usefully taken to promote the co ordination, improvement, and development of transport generally, is the only recommendation made, although the future of co ordination is discussed

THE debate on the second reading in the House of Commons of the Representation of the People (No 2) Bill took place on Feb 3 Several points in connexion with university representation in parliament were discussed during the debate Statistics were quoted by Sir J Withers, who stated that of the 12,000 university voters (NATURE, Jan 31, p 183), 10 per cent are living abroad, not, as has been suggested, as pleasure seekers, but as tea planters, consuls, Civil servants, and men of business He considered their votes of great value, especially where foreign policy is concerned He protested strongly against the proposed abolition of the university vote, on the grounds that the proposal was the result of a cynical bargain for party advantages, to get rid of Conservative members of the House, rather than a consideration of the public interest Miss Rathbone pointed out the value of such representation, in that special channels were thus supplied through which mental training could express its views Sir Graham Little stated that the reason for the removal of the twelve members had been quite frankly shown by Mr Clynes, when he said that those members were mainly Conservatives

IN defence of the Bill, especially the question of the abolition of university votes, Mr Ramsay Macdonald said that, at the present time, university representation is simply plural voting If any institution in the country requires special representation, it certainly is not the universities The universities pervade the whole atmosphere of the House, they are represented in every party and on every bench, because of the culture and enlightenment which the universities have spread among all classes of society On Feb 2, during the motion for the second reading, Mr Clynes said that whatever else university members may have exhibited, they have shown in the quality of their work in the House of Commons a lack of knowledge of public needs Mr Shaw, during the debate, expressed the view that university graduates should be content with the influence which their university training can give them in the community, without asking for a separate parliamentary vote At the division, 295 voted for the second reading and 230 against, giving a Government majority of 65

THE general secretary, Prof C Marie, of the committee for the publication of the "Annual Tables of Constants and Numerical Data (Chemical, Physical, Biological and Technological)", informs us that Dr M Volmer, professor of physical chemistry and electrochemistry at the Technische Hochschule in Berlin, has been elected a member of the permanent committee, and Prof M Bodenstein as honorary member of this same committee Prof W A Roth, editor of "Landolt Börnstein Tables", has agreed to participate in the editing of the thermo chemistry sections of the forthcoming volumes These nominations of German representatives are greeted with particular satisfaction, as they put an end to a situation for which events alone were responsible, but which were no less regrettable from a scientific point of view

ACCORDING to the tenth annual report of the British Electrical and Allied Industries' Association (E R A), being presented at the annual general meeting on Feb 13, the Association's income seems to be assured, and will, it is hoped, soon reach £50,000 a year. The work has recently been reorganised so as to secure that research is undertaken for the benefit of the industry as a whole and not merely for particular sections of it Provision has now been made to wind up all 'confidential researches' at the end of the year, the rights of interested sections in certain confidential work being safeguarded Some of the work done is mainly of technical interest, but some of the reports disclose phenomena which are of a more general interest At first sight a report of the effect of storage in a warm atmosphere on the properties of adhesive electrical insulating tapes seems purely technical; but it may well give rise to research of interest to physicists The research on the heating of cables buried deeply in the earth has led to important conclusions The experiments show that the thermal resistivity of the soil diminishes with the depth, and

hence cables carrying heavy currents can get rid of more of their heat than had been anticipated This tends to compensate for the greater distance from the earth's surface, and so the carrying power of deeply buried cables is not necessarily worse—and is indeed sometimes better—than that of cables buried only two or three feet below the surface This is generally due to the fact that the soil is more compressed at the greater depths The experiments show the necessity of studying closely the difficult problem of the movements of the moisture in the soil, under the influence of the thermal gradients due to the heating of the cables Methods have also been devised of improving the thermal conductivity in the neighbourhood of the buried cables

THE Hurter Memorial Lecture delivered by Prof G T Morgan before the Liverpool Section of the Society of Chemical Industry, on Jan 16, gave a survey of recent developments in organic syntheses through the use of pressure The original impetus in this field came in the production of intermediates for dyestuffs, and the experience thus gained by the great German firms was of fundamental importance in the development of the ammonia synthesis, and afterwards, following the study of the reactions between carbon monoxide and hydrogen at high temperatures and pressures in presence of catalysts in the manufacture of methyl alcohol Prof Morgan is still hopeful that the synthesis of ethyl alcohol and higher alcohols is possible, without a simultaneous loss of carbon monoxide, by complete reduction to methane Dealing with oxidation under pressure, the production of $\alpha\alpha'$ dipyrryl, with a bispyrrypyridine, which gives a remarkably stable ferrous co ordination compound with iron, from pyridine and anhydrous ferric chloride at 350° and about 50 atmospheres, was cited Reference was also made to studies on the Kolbe Schmidt reaction and on the action of carbon dioxide on phenols and on amines in the presence of anhydrous metallic chlorides, which are still yielding results of importance in the dyestuffs field Prof Morgan believes that a systematic study of high pressure reactions will lead to discoveries whereby the use of pressure may be partly or entirely avoided, and points out that, as the discovery of more effective catalysts lowers reaction temperature, high pressure synthesis should approximate more closely to the elaboration of complex carbon compounds, associated in Nature with the vital activities of plants and animals

AN interesting legislative experiment is apparently to be made in the United States Science Service reports that Congress has unanimously passed a law which gives to the man who produces new plants "the same encouragement and protection that the inventor of new mechanical or electrical apparatus has received for more than a century" New plants can be patented, and for seventeen years the breeder of a new plant will have a monopoly on its production It is added that, as yet, full procedure for handling plant patents has not been worked out When this has been done, possibly the authorities may discover some difficulties in the way of this new legislative project Plants propagated from seeds and from tubers are apparently excluded from its operation, but fruit trees, ornamental shrubs, etc, which can be vegetatively propagated come under its operation: it is not clear on what principle the tuber, a vegetative mode of propagation, should be excluded when other vegetatively propagated plants are included, but its exclusion may considerably reduce legal actions contesting patents under the new act It will be interesting to see how the breeder establishes his claim to a new plant under the law If he states that his new plant is the result of hybridisation between two named parents, how will this affect the operation of other breeders who desire to make the same cross? Will the same effect be ruled to follow, in law, if the same parents are used in the same manner upon another occasion?

AT Daytona Beach, on Feb 5, Capt Malcolm Campbell beat the world's land speed record, which was set up by the late Sir Henry Segrave at the same place on Mar 11, 1929 Major Segrave's average speed over the measured mile was worked out as 231 36226 miles per hour, and the new record achieved by Capt Campbell works out as 246 154 miles per hour Exceptional credit is due to Capt Campbell for his feat, since conditions were far from good Visibility left much to be desired and the course was found to be uneven in places, especially at the northern end These drawbacks did not deter him, however, and he set out, taking a flying start of 5 5 miles, which is 1 5 more than usual His car, the Napier Campbell *Blue Bird*, was fitted with a supercharged Napier aero engine, similar to those of the Supermarine seaplanes used in the Schneider Trophy contest in 1929 The engine develops more than 1400 horse power The speeds returned for Capt Campbell were southward run, 246 575 miles per hour, northward run, 245 733 miles per hour—or an average of 246 154 miles per hour

COTTON that has been grown entirely in England will be displayed in the Empire Marketing Board's stand at the British Cotton Textiles Exhibition which opens at the White City, London, on Feb 16 Less than 30 miles from London there are 'cotton fields' complete with plants which have flowered, fruited, and flourished for three generations Specimens of various types of cotton grown in glass houses at the Rothamsted Experimental Station will be shown alongside cotton from seven Empire countries The plants have been grown for the purpose of scientific study of 'black arm' disease, which attacks cotton in the Sudan, Nigeria, and Uganda It is due to a bacterium which causes the young plants to wilt and die, and in another form, 'angular leaf spot', attacks the leaves and prevents the plant from producing lint A grant has been made by the Empire Marketing Board for a study of the causes and spread of infection, and how 'black arm' may be checked Six tanks have been erected in which the temperature of the soil and the atmosphere, the humidity, and the amount of light can be controlled by those in charge The workings of these tanks—the only apparatus of its

kind in the country—are to be shown by means of an exhibit of photographs, and cultures of the disease will also be exhibited

In continuation of the series of special exhibitions to illustrate the resources of raw materials of the British Empire which have been given at the Imperial Institute, a special exhibition of the mineral resources of the Empire will be opened by Mr Amery on Feb 17 This exhibition, besides bringing out some facts which are little realised by the general public—for example, the vast wealth of minerals produced within the Empire as compared with the rest of the world—will also show the utilisation of some of the lesser known minerals, which are nevertheless of great importance Again it is not generally realised that 90 per cent of the world's nickel output, 90 per cent of the asbestos, and 72 5 per cent of the world's gold output were produced within the Empire in 1928 Sir Robert Horne will give an address on the mineral resources of the Empire in the cinema at the Imperial Institute at 5 30 P M on Thursday, Feb 19 The seating accommodation is limited, and those desirous of attending should communicate early with the Secretary Imperial Institute, London, S W 7 There will also be a special series of mining films shown in the cinema throughout the exhibition Entrance will be free In connexion with the exhibition, the Institute is publishing a handbook on the mineral resources of the British Empire

It is announced that a course of lectures on "The Application of Anthropology to Practical Affairs in Africa" will be given by the Rev Edwin Smith at the London School of Economics on Mar 9, 10 and 11 at 5 P M The manner in which the lecturer will deal with his subject, as outlined in the announcement, suggests a thoroughly practical handling of the question both in the interests of the future administrator and others concerned with native affairs and from the point of view of the scientific investigator Rapidly changing conditions among backward peoples must, sooner or later, bring the anthropologist face to face with the question of the best way to deal with his problems in the field Is his aim to be directed towards the elucidation of native institutions, in so far as it is possible to ascertain their original form, or is he to record them as they now are and register their function in changing conditions? If anthropology is to serve as an applied science, it may not appear that the matter is open to question This is, no doubt, one of the points which Mr Smith will discuss, and upon which his knowledge of African conditions entitles him to respectful hearing In his first lecture, he will consider if we are on the right lines, in view of the Government's declaration with reference to the value of anthropology In his second lecture, African family life and the regulation of the sex impulse will be considered as a type problem calling for sound knowledge as a basis of any action, and in the third, he will deal with the changing African, and consider whether what the African is becoming, rather than what the African was, is a necessary study if anthropology is to help in the solution of African problems

In an age when iron is produced in enormous quantities and when scrap iron is scarcely worth picking up, it is difficult to realise the conditions in the fourteenth century, when, as stated by Rogers, on a farm "the most formidable item of expenditure on the supply of necessary dead stock was the annual cost of iron" The value of iron then was probably well over £100 a ton in our money, and even in the latter half of the seventeenth century wrought iron was twice as dear as rolled lead Such are some of the statements given in the authoritative paper by Mr J W Hall on "The Making and Rolling of Iron" contained in the recently published vol 8 of the *Transactions* of the Newcomen Society Originally produced direct from ore in quantities of 7 lb at a time, 'manufactured iron' even 250 years ago was made in a finery not much bigger than a smith's fire One great difficulty was the limited supply of charcoal, and between 1720 and 1750 the make of bar iron in the whole of Great Britain was only 250 to 350 tons a week The principal steps in the history of iron making include the use of coke in the blast furnace, Cort's invention in 1784 of 'dry' puddling on a sand bottom in a reverberatory furnace, and Joseph Hall's improvement in 1839 when he lined his puddling furnace with a partially fusible oxide of iron, an improvement which completely established the reputation of South Staffordshire bar Brown's first chain cables for the Navy, costing 6d a lb, were made of this bar, and it is the chain cable trade which to-day provides the chief outlet for the same material In the working up of the iron, the trip hammer was used with great skill, and such hammers were used for iron long after rolling had been adopted for other metals Slitting mills were in use in England in 1590 Rolls for iron were first used merely for finishing to size, but Cort's patent of 1783 laid the foundation of the existing methods of rolling sections

A third international conference on bituminous coal will be held at the Carnegie Institute of Technology in Pittsburgh, Pa, in November next, again organised by Dr Thomas S Baker, president of the Institute of Technology Prominent fuel technologists from all parts of the world will be invited to attend the conference In connexion with the organisation of the meeting, Dr Baker has visited Europe to invite prominent scientific workers to speak at the congress The purpose of the conference will again be to present for discussion the results of recent studies in coal, and particularly the economics of the new methods and processes that are being evolved The programme will include papers on carbonisation, liquefaction, and gasification of coal; by-products of coal; the mechanism of combustion; cleaning of coal and its preparation for the market; pulverised fuels; power plants, and domestic heating The advisory board supporting Dr Baker includes J A Farrell, president of the United States Steel Corporation; J H Hammond, mining engineer; F B Jewett, president of the Bell Telephone Laboratories; A W Mellon, Secretary of the United States Treasury; F A Merrick, president of the

Westinghouse Electric and Manufacturing Company, A G Pratt, president of the Babcock and Wilcox Company, H B Rust, president of the Koppers Company, M S Sloan, president of the New York Edison Company, G Swope, president of the General Electric Company, and W C Teagle, president of the Standard Oil Company of New Jersey It is hoped that the conference will assist in discovering new processes and help the recovery of the coal industry

THE council of the Institution of Electrical Engineers has made the tenth award of the Faraday Medal to Mr Charles H Merz, a well known electric power and traction engineer The Faraday Medal is awarded by the council of the Institution, not more frequently than once a year, either for notable scientific or industrial achievement in electrical engineering or for conspicuous service rendered to the advancement of electrical science, without restriction as regards nationality, country of residence, or membership of the Institution

THE following appointments to the Colonial Agricultural Service have recently been made by the Secretary of State for the Colonies Mr H Wolfe, deputy director of agriculture, Tanganyika Territory, to be deputy director of agriculture (plant industry), Kenya, Mr N D Simpson, to be systematic botanist, Ceylon

THE Empire Marketing Board has approved a grant, for two years, for an investigation into the technique of milk examination by the London School of Hygiene and Tropical Medicine The present standards for the bacteriological grading of milk were established in 1923 It has since become clear that they are not sufficiently complete, and, in view of their great importance in securing a thoroughly reliable 'clean milk' supply, it has been decided to work out a new technique to be accepted as the official standard in all cases of litigation

WE regret that an error was made in our reference to the new catalogue of lantern slides issued by Messrs Flatters and Garnett (NATURE, Feb 7, p 211) Chief credit for this production was given to Mr Flatters We understand that Mr Flatters has not been in the business for many years, and that the compilation of the catalogue (especially the botanical section) was due mainly to Mr Henry Garnett

THE Wellcome Foundation, Ltd, is to erect a new medical and chemical research building at the corner of Gordon Street and Euston Road, London, W C 1, on the site, 225 feet by 135 feet, now partly occupied by its Bureau of Scientific Research For many years the Foundation has maintained medical and chemical research laboratories, but recent developments have made it necessary to co ordinate and extend these activities The new building will furnish the additional accommodation required, and be provided with the most modern research equipment The architect is Mr Septimus Warwick

THE 1932 meeting of the Iron and Steel Institute will be held in the United States of America, under the presidency of Colonel Sir Charles Wright, Bart. Joint arrangements, with reference to ocean and inland travel, are being made with the Institute of Metals, which is also holding a meeting in the United States in 1932 The inclusive dates for the meetings and excursions are Sept 12–Sept 29 The cost of the trip will be approximately £125 for the round journey, the major portion of this may be paid in advance, on an instalment plan, which began this month Plans are under consideration for participation in some form by the Canadian Institute of Mining and Metallurgy, either at Toronto or Montreal, or both

THE thirty sixth general meeting of the Deutsche Bunsen Gesellschaft fur angewandte physikalische Chemie, the leading association of research workers, scientific workers, and technologists in Germany in the field of applied physical chemistry, will be held on May 25-27 in Vienna The subject of the symposium will be "Recent Progress in the Science of Metallurgy with particular reference to Light Metals" The arrangements have been undertaken by Prof Speckéter, director of the I G Farbenindustrie A G, managing director of the Griesheim Elektron works

THE Faraday Society has arranged a general discussion on "Photochemical Processes" to be held in the chemistry department of the University of Liverpool on April 17 and 18 Several distinguished chemists and physicists from the United States and the Continent have been invited to attend the conference and to send contributions There will be four sessions, each with an introductory paper, which, like all the contributions, will be distributed previously, and taken as read The four subjects are "Molecular Spectra in Relation to Photochemical Change", "Photochemical Kinetics in Gaseous Systems", "Photochemical Change in Liquid and Solid Solutions", and "Photosynthesis" The introductory papers respectively are by Prof R Mecke, Prof M Bodenstein, Prof Berthoud, and Prof E C C Baly

FROM a recent article in *De Visscherij Courant* it appears that the slipper limpet is multiplying in the waters of Zealand in Holland Frequent warnings by the coastal fishery authorities at Amsterdam have been issued, pointing out the necessity of exterminating these parasites in their early stages As the food of the slipper limpet is the same as that of the oyster, it is feared that a great multiplication of the pest would have a serious effect upon the quality of the Zealand oyster The Ministry of Agriculture and Fisheries desires to impress upon all persons who import Dutch or other foreign oysters, for the purpose of relaying, the importance of taking every precaution to avoid laying down oysters with slipper limpets attached to them Every oyster should be examined for slipper limpet spat before it is laid down, for once the slipper limpet has become established on an oyster ground, it is practically impossible to eradicate it

AMONG the many hazards of mining, one of the most difficult to avoid is the production of sparks by impact of rock, or of steel pick and rock It has been

shown that the picks of mechanical coal-cutters can strike sparks which will ignite firedamp In a recent report (No 62) issued by the Safety in Mines Research Board, M J Burgess and R V Wheeler report experiments which show that sometimes the impact of a hand pick on suitable hard stone will ignite firedamp It was not easy and the work suggests that the production of suitable conditions is a rare occurrence in practice

Messrs Francis Edwards, Ltd, 83 High Street, Marylebone, W 1, have just issued a useful little list of some 350 second hand works dealing with the arctic and antarctic regions

Applications are invited for the following appointments, on or before the dates mentioned —An assistant aeronautical engineer in the Army Air Corps of the Irish Free State—The Secretary, Civil Service Commission, 45 Upper O'Connell Street, Dublin C 8 (Feb 24) An adviser in greenkeeping at the St Ives Greenkeeping Research Station—R B Dawson, St Ives Research Station, Bingley, Yorks (Feb 28) An assistant woman demonstrator in physics at Royal Holloway College—The Principal, Royal Holloway College, Englefield Green, Surrey (Mar 4) A professor of mechanical engineering in the University of Birmingham—The Registrar, The University, Edgbaston, Birmingham (Mar 9) A director of the Institute of Plant Industry, Indore, and agricultural adviser to States in Central India and Rajputana—The High Commissioner for India, India House, Aldwych, W C 2 (Mar 14) A head of Biological Department of Epsom College—The Headmaster, Epsom College, Surrey (Mar 31) A professor of philosophy at King's College, London—The Academic Registrar, University of London, South Kensington, S W 7 (May 7) A part-time assistant master, qualified to teach biology, at the Technical Institute, Gillingham—C Colles, Medway Technical College, Gillingham, Kent A resident engineer at the Rotherhithe Works of the South Metropolitan Gas Company—The Secretary, South Metropolitan Gas Company, 709 Old Kent Road, S E 15 A science master for physics at the Newport, Isle of Wight, Secondary School—The Director of Education, County Hall, Newport, Isle of Wight

Our Astronomical Column

Jupiter without its Satellites —Mr W F Denning writes "The planet Jupiter will be observed apparently without visible satellites on Feb 14 On that evening at 8 51 P M the first satellite will commence its transit across the disc of its primary The fourth satellite will have previously begun its transit, while the second satellite will be hidden behind the planet, and the third will be suffering eclipse The temporary obscuration of the satellites will continue for more than 2 hours and 15 minutes, for at 9 6 P M the first satellite will complete its transit Jupiter has nine satellites, all but five are so faint that small telescopes cannot reveal them To view the planet devoid of all visible satellites is a somewhat rare spectacle The writer was privileged to witness it on Aug 21, 1867, with a 4¼ in refractor, and a delineation of the appearance presented was afterwards given in the *Astronomical Register* Repetitions of the phenomenon will occur in 1932, and one of these which occurs in November may possibly be seen at Greenwich"

Pluto —A recent *Daily Science News Bulletin* issued by Science Service, Washington, D C, reports that Dr S B Nicholson and N U Mayall, of Mount Wilson, have been studying the mass and orbit of Pluto They first obtained corrections to Pluto's orbit by applying perturbations by the large planets, the period appears to be very close to 248 years With the orbit thus obtained they investigated the mass that was indicated by the observations of Neptune The two planets were in conjunction in longitude in 1891, and at their least distance apart, 19 units, in 1895 They made use of the data given by Dr J Jackson in his paper on Neptune's orbit (*Mon Not Roy Ast Soc*, June 1930) Two different methods of treatment, one including, the other excluding, Lalande's observations of 1795, gave for Pluto's mass 1 08 and 0 72 in terms of the earth's mass

Even the smaller of these masses would require the diameter of Pluto to be at least 7000 miles, assuming that the density is unlikely to exceed that of the earth Such a diameter is not impossible. With an albedo the same as that of the planet Mercury, it would make the visual magnitude in opposition about 14 The visual magnitude was stated to be brighter than the photographic one, and some of the estimates made it as bright as 14 M Baldet, using the 33-inch Meudon refractor, estimated the diameter as 0 2", or about 4000 miles But the limbs would be so feebly illuminated that the real diameter may be greater than his estimate

Solar Physics Observatory, Cambridge —The eighteenth annual report of the director of the Solar Physics Observatory, Cambridge, covering the period Aug 1, 1929–July 31, 1930, shows satisfactory progress, although much of the routine work has been hampered by somewhat extensive instrumental alterations, which, however, should greatly assist the work in future In particular may be mentioned the installation of an electric Gerrish drive for the 36 inch Common reflector in place of the old clock drive, and the re designing of the spectroheliograph The loss which the observatory has sustained through the sudden death of the first senior observer, Mr F E Baxandall, in October last, is referred to in appropriate terms Mr Baxandall's chief unfinished investigation, on the spectrum of β Lyræ, has been edited by the director, with the collaboration of Dr F Hogg, director of the Amherst Observatory, and published as vol 2, part 1, of the *Annals of the Solar Physics Observatory* An important addition to the instrumental equipment is a registering microphotometer, specially designed by the Cambridge Scientific Instrument Co, in close collaboration with the assistant director, Dr Carroll, the purchase of which was facilitated by a generous donation from Mr J H Reynolds, honorary treasurer of the Royal Astronomical Society A full description of the instrument has recently appeared in the *Monthly Notices of the Royal Astronomical Society* On the meteorological side, the results of a study, during the last five years, of the discharge of electricity from an elevated metal point during periods of disturbed weather conditions have been discussed in a paper presented to the Royal Society An extension of this work is now in progress.

Research Items.

A Benin Ivory.—In *Man* for January, Capt T A Joyce figures and describes a carved ivory ewer from Benin recently presented to the British Museum by the Christy Trustees The ewer is made of a section of elephant tusk covering an iron lining which is prolonged into a lip everted over the ivory jacket An iron foot also everted has been added at the base A wooden handle is fitted at the side, obviously a later addition, as it cuts into the carved design at the lower point of junction with the vessel The entire exterior of the ivory is covered with carving in rounded relief The ornament is arranged in two horizontal bands separated by a band carved in interlaced pattern At the base of the ewer is a second band of interlaced carving In the upper register is represented a catfish, a centipede, a frog, a two headed bird, and a fish, in the lower an elephant's head, a crocodile seizing a fish, and a grazing antelope The designs are excellent examples of the tendency towards symmetry characteristic of artists of all ages The elephant's head is seen from above, the tusks and ears have been curtailed to fit the space, and the trunk is divided into two diverging sections, each terminating in a human hand holding a branch The specimen is believed to be unique It was probably carved soon after Portuguese power began to spread on the west coast of Africa in the sixteenth century The shape of the ewer suggests European influence, but the artist has preserved his native style in all its purity The ewer is 9 2 in in height

Ancient Coastal Cultures of Northern Peru.—The results of a second Marshall Field Expedition to Northern Peru in 1926 are described by A L Kroeber in vol 2, No 2, of the *Memoirs*, Anthropology, of the Field Museum, Chicago The objective of the expedition was the coastal area between Lima and Nazca, and the aim to determine the cultural relations of the northern and southern Chimu areas and the cultural sequence within each The cultural history of the northern Peruvian coastal area may be summarised as follows (1) *Early Chimu* (formerly Proto-Chimu) This affords the first archæological evidence for a well developed culture of specialised type No origin or formative period is known, and no attempt to connect it with Ecuador, Central America, or Mexico has proved valid The people built terraced, small topped pyramids, higher than any erected el[illegible]ere in Peru The dead were buried in rectangular c[illegible]umbers, in a variety of positions Gold, copper, and their alloys, and perhaps silver, were melted and cast Tin and bronze were unknown The pottery was the highest achievement of any South American culture or people (2) *Middle* or *Tiahuanaco* appears to be an overrunning of an intrusive culture, possibly people, from the highlands It is represented at relatively few sites, and chiefly from its pottery, which is in fragments (3) *Late Chimu* Fundamentally an emergence of Early Chimu with [illegible]rements Now Chimu culture was no longer [illegible]ial, but extended far to the north of the [illegible]u domain Here it may have been ancient and [illegible] spread south At the moment of transition from prehistoric to historic, when the Incas conquered the Chimu area, the whole of the northern coast was under the influence of a ruler who lived at Chanchan Pyramids were no longer as high as under Early Chimu, and had broad tops, which were used for interments The custom prevailed of placing a small piece of copper in the mouth of the dead Metal was abundant; but bronze articles were in a minority. In textiles, mountain wool gave way to a preference for all-cotton fabrics Pottery had settled into a syncretised style of little originality but facile elegance The conquest of the Incas appears to have had little effect on Chimu culture, which indeed was externally prosperous and perhaps spreading up to the time of the Spanish Conquest

Rice as Food.—Among the populations of various countries the value of rice as a foodstuff is receiving increasing recognition, with the result that the consumption is gradually gaining ground Thus, in France, following an appeal by Prof Achard on behalf of rice grown in the French colonies, the importation has recently risen by more than 30 per cent In Italy, however, the cultivation of rice, far from expanding, is losing way, in spite of the fact that the soil and climate of certain districts are admirably suited to the production of rice of the highest quality Moreover, although Italy could produce twice or thrice its actual consumption, very little rice is being exported In an article published in the *Rendiconti* of the Royal Lombardy Institute of Science and Letters (Parts 11-15), Prof Luigi Devoto points out that the experience of the past few years has fully confirmed the view that, when properly prepared, rice is of great value, not only to healthy persons, but also to patients suffering from infectious diseases, affections of the digestive organs, certain skin diseases, obstinate lack of appetite, hyponutrition, and a number of other complaints In view, also, of the large amount of labour employed in the cultivation and marketing of rice, the question is one of considerable national importance at the present time, and Prof Devoto emphasises the advantages that would accrue from more extended production and consumption of this commodity throughout Italy

West Indian Fishes.—H W Fowler, in his paper, "The Fishes obtained by Mr James Bond at Grenada, British West India, in 1929" (*Proceedings* of the Academy of Natural Sciences of Philadelphia, vol 82, 1930), records eighty species, two of which are new, and several others are of special interest, since the fishes from this rich region are very little known Figures and detailed descriptions are given of the two new species, *Ariomma bondi*, the first of this genus from the Atlantic, closely related to the Hawaiian *Ariomma lurida*, and *Malacoctenus bondi*, which is recognisable by its colour markings

Polish Cladocera.—M Ramuet has described the cladoceran fauna of the lakes in the coastal region of the Polish Baltic, "Untersuchungen uber die Cladoceran fauna des polnischen Ostseekustenlandes" (*Bulletin International de l'Académie Polonaise des Sciences et des Lettres* Classe des Sciences Mathématiques et Naturelles, série 3 Sciences Naturelles (II), N 5 6, B II, 1930) There are ten large lakes, from 3700 metres to 380 metres in length and 900 metres to 270 metres in breadth, and several smaller lakes of various kinds, some of which are in the neighbourhood of peat moors The larger lakes have a moderately developed coast line, and are without islands and deeply indented bays A short description of each lake with notes on the flora is given, and in some cases the more important animals Fishes abound in most of the large lakes and usually the bivalve *Dreissensia polymorpha* is found in large quantities In the systematic portion a record is made of the species of *Cladocera* in each lake, which show a certain similarity and belong to a type characterised by the presence of *Diaphanosoma brachyura*, *Daphnia cucullata*, and

Bosmina longirostris Seventy species in all are now known from the coastal regions of West Prussia, including those from the Polish coast land and the Danzig Free Territory The paper is well illustrated by photographs of the lakes themselves and their surroundings, and by line drawings of the *Cladocera*

Musculature of the Larval Shrimp —The report for 1929 on the Lancashire Sea-Fisheries Laboratory at the University of Liverpool, edited by Prof James Johnstone and Dr R J Daniel, contains papers on the hydrographic observations made during 1926–29 by Dr Daniel, on the surface drift bottle experiments in the Irish Sea, July 1925–June 1927, by Dr Daniel and Miss Mabel Lewis, and on the abdominal muscular system of the zoea and mysis stages of the shrimp (*Crangon vulgaris*) and their bearing on phylogeny, by Dr Daniel The hydrographical investigations have been carried out with the assistance of grants from the Ministry of Agriculture and Fisheries Sea water samples were collected from the Irish Sea between Holyhead and Dublin, and at the same time drift bottles were liberated from the places where the water samples were taken Dr Daniel's work on the musculature of the larval shrimp is of much interest Following his former papers dealing with the adult shrimp (*Crangon vulgaris*) and the mysid *Praunus flexuosus*, in which work distinct differences were found in the muscles of the two species, the present paper investigates the larvæ of *Crangon* Even in the first stage, the so called zoea, the muscles are very like those of the adult, which fact might be regarded as direct evidence against its schizopod ancestry A more probable interpretation is, however, that as the metamorphosis is much abbreviated compared with some of the more primitive Crustacea, such as most of the euphausiids, the development is compressed by the early addition of adult characters, and that during the larval period adult organs or characters as well as complete larval stages may be anticipated The author is of the opinion that "it may be taken that the occurrence of adult muscular structure in the zoea and mysis of *Crangon vulgaris* is a further indication of this gradual suppression of complicated larval series in the higher Crustacea "

Root and Shoot in the Angiosperm - Mrs Arber has recently published in a more extended form (*New Phytologist*, **29**, Dec 1930) the discussion of this subject that she presented at the International Botanical Congress at Cambridge From the point of view of formal morphology she concludes that stem and leaf should not be treated as discrete morphological entities, but that root and shoot belong to primary and equivalent morphological categories She points out, in this latter connexion, that root and shoot alike normally give rise to other like units, the shoot producing lateral shoots, the root lateral roots This conception of the morphological equivalence of shoot and root seems to meet with little difficulty in the dicotyledon, but the fibrous root system of the monocotyledon, often forming anew at each node and with no very permanent main system as a prolongation of the main axis, may raise a doubt as to whether this view is fully in accordance with all the facts There are obvious difficulties in the way of extending this view to include the relations of shoot and root system in the Filicales The paper contains an interesting review of various morphological facts, gathered mainly from the author's investigations of the Gramineæ, which bear upon the relation of leaf and stem Thus, leaves terminal upon the axis are described from three genera of grasses Axes with dorsi ventral symmetry are cited, as well as leaves with characteristically radial organisation

Bathymetrical Work in the Baltic —Various charts of the northern part of the Gulf of Bothnia show notable divergences, especially in deeper water. These are due no doubt to different interpretations of the soundings With the view of obtaining a detailed bathymetrical chart of that part of the Baltic, it was surveyed with an echo sounder in the summers of 1927–29 The methods and results are described by H Renqvist in *Havsforsknings Institutets Skrift*, No 68 (Bathymetric chart of the Bothnian Bay and the North Kvark) Several thousand soundings were taken and allowed the construction of a detailed map showing an extraordinarily uneven floor, a state of affairs that was overlooked in the deeper water when few data were available Dr Renqvist insists that many of the former discrepancies were due to soundings having been wrongly placed on the chart On an irregular floor a slight error in position might well have a wide result He claims that errors arise when a ship has to stop for sounding, for it is then difficult, without cross bearings to land, to fix the true position, since the slowing down and restarting of the ship vitiate calculation of average speed and so of position. In echo sounding there is a uniform speed on the definite course throughout, and the shorter time occupied in taking such a line of soundings reduces the period during which one is unable to take bearings to the land This also obviates sources of error

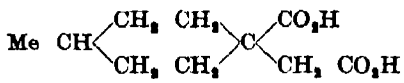
The Gas Equation —In the issue of the *Physikalische Zeitschrift* for Dec 1, 1930, Dr E Neusser, of the Vienna Technical High School, examines the experimental material available for hydrogen and carbonic acid gas in order to determine the variations with pressure and temperature of the two quantities a and b of van der Waals' gas equation Observations of volumes at two pressures near together and at the same temperature are used to calculate a and b over as wide a range as possible The units used are the litre, atmosphere, and gram molecule of the gas In both gases a and b are found at constant temperature to decrease with the pressure, the curves for a and b being very similar At constant pressure above the critical point both a and b increase with increase of temperature, while below the critical point there is a rapid fall of both a and b from their values for the gas to their values for the liquid For the lowest temperatures for which the values have been calculated the decrease is of the order of 50 per cent The curves given in the paper show why the attempts to modify the van der Waals equation to bring it into closer agreement with observation[illegible] met with so little success

Aero-navigation by Wireless —The difficulties which have to be overcome in navigating an aeroplane in a fog, which the light from a beacon cannot penetrate, seem at first sight to be almost insuperable As it cannot remain at rest like a ship on the sea, it is sometimes forced to make a dangerous landing In the *Proceedings* of the United States National Academy of Sciences for Nov 15, Messrs H Diamond and F W Dunmore, of the Bureau of Standards, describe a method of landi[illegible]n with the [illegible]se fog When flying overland two [illegible]chase of [illegible]erving sets are used One is the usua[illegible] which receives the radio beacon signals when flying between cities, and also spoken orders For landing at the proper angle, a short wave receiver is used, the signals having a wave length of 3 metres The aeroplane flies midway between waves coming from two beam antennæ When the aeroplane is steering in the correct direction, the amplitudes of the vibrations of two reeds on the pilot's board are equal When it moves to the right or the left of the true course, this is shown

at once by one of them having a larger vibration than the other. A somewhat similar arrangement, using lower power and a smaller loop antenna, is used to give the pilot the direction of the runway on which he is to land. The pilot knows when he is approaching the boundary of the field on which he intends landing, as he hears a special signal in the headphones which gets louder as he approaches the field but disappears completely when he is directly over the antenna, which is placed on the edge of the field. To tell the proper angle at which he is to glide, high frequency signals are directed along a narrow beam. The line of greatest signal strength is along the axis of the radio beam, and at a short distance away it drops considerably. The pilot should hit the axis of the beam and then start to drop, keeping the signal strength constant, the approach to the transmitter compensating for the greater distance from the axis. This gives very approximately the proper landing curve; the instrument indicates whether he is flying too high or too low. A vertical pole antenna and a horizontal doublet antenna fixed on the aeroplane are used to receive the landing system signals.

Determination of Reducing Sugars.—Schuette and Terrill, in the December number of the *Journal of the American Chemical Society*, describe experiments on the use of cupropotassium carbonate solution, first proposed by Soldaini in 1876, in the determination of reducing sugars. They investigated four types of solution and show that it is doubtful whether Beyersdorfer's form of the solution can be used as a selective reagent for levulose, as has been asserted. The effects of varying the experimental conditions were fully studied and mathematical expressions described.

Strainless Ring Structure in Cyclohexane.—In a communication to the Editor, Dr. Muhammad Qudrati-Khuda, of Presidency College, Calcutta, states that he has found evidence of a 'strainless ring' structure in cyclohexane. He has discovered that 4-methyl-cyclohexane-1-carboxy-1-acetic acid,



is capable of existing in four stereoisomeric modifications. The stabilising of these forms is attributed, as in decalin, to a restraint of the internal rotatory movement of the carbon atoms, brought about in this case by substituting heavier groups for some of the hydrogen atoms of cyclohexane. A fuller account is to be published shortly.

Molecular Iodine.—The separation of two forms of molecular hydrogen (both being represented by the formula H_2) has naturally raised the question of whether other diatomic gases can be similarly treated. From its band spectrum it would be anticipated that this should also be possible with iodine, and an attempt on this substance, which appears to have been partly successful, is described by R. M. Badger and J. W. Urmston in the December number of the *Proceedings of the National Academy of Sciences*. The method adopted was photochemical; only one form is excited by exposure to the green line of mercury (λ5461), and this can then be removed by a reaction with hexene. After a prolonged treatment, evidence was obtained that the residual iodine molecules had different fluorescent properties from the original mixture of the two forms, but the amount of separation which had been effected was evidently not large. The reasons for this are not clear, but the authors consider the method sufficiently promising to be followed still further.

Specific Heats and Entropies of Metals.—The specific heats of thallium, calcium, and magnesium from 10° to 200° abs. have been determined by Clusius and Vaughan, whose results are given in the December number of the *Journal of the American Chemical Society*. The extrapolation to absolute zero could be made with some certainty, and thus the absolute entropies calculated. The results for the atomic heats were higher in the case of thallium and lower in the case of magnesium and calcium than those of previous workers. Whilst in the case of calcium (which was found difficult to free from hydrogen), the atomic heat curve could be very approximately represented with a single Debye function, this was not possible with thallium, the θ value of which decreased below 17° abs., nor with magnesium, the θ value of which increased appreciably below 30° abs. A more rapid decrease of atomic heat than is to be expected from the T^3 law has previously been observed only with copper and tungsten. The vapour pressure constants are calculated from the results. Although the error is of the order of 25 per cent, it is claimed that it agrees very well with that given by the usual statistical formula (0·443 and 0·493); the entropy of magnesium vapour at 1 atm. and 25° being 35·29 units determined empirically and 35·51 from theory.

Entropy of Hydrogen.—Recent progress in the development of statistical mechanics and the discovery of the two forms of hydrogen molecule foreseen by the wave theory have made it necessary to revise carefully the calculation of the entropy (or free energy) of hydrogen from spectroscopic and other data. This question is dealt with in two papers by Giauque in the December number of the *Journal of the American Chemical Society*. In the first of these a considerable simplification is introduced into the method of calculating the free energy from spectroscopic data. Every state is assumed to possess the same statistical weight; the statement that a certain state has an *a priori* weight of three means that the state is really three states which have been grouped together for simplicity of calculation, having so nearly the same energies that they are affected in nearly the same way by temperature but really individual states in a statistical sense. Previous calculations are shown in some cases to be in error. A simple new derivation of Reiche's well-known equation

$$S^\circ = R[\ln Q_r + T\, d \ln Q/dT]$$

is given and it is believed that this equation will hold for all states, including multiplicities due to nuclear effects such as spin. When the necessary atomic or molecular levels are known Q may be calculated. In the second paper the author considers the case of hydrogen, on the basis of recent data (NATURE, Mar. 22, 1930, pp. 462-463), and "the numerous misunderstandings which have arisen concerning the effect of nuclear spin on the entropy of hydrogen" are cleared up. A new calculation of the heat capacity of hydrogen, without assuming rigidity of the molecule, is given. The absolute entropy of hydrogen at 25° C. is found to be 33·98 cal. per 1° per mol. This, however, is not the value to be used in combination with $\int C_p \ln T$ for other substances, since an entropy of mixing must be subtracted on account of the existence of ten kinds (one para- and nine ortho-) in the solid. A detailed discussion of this point is given, and it is concluded that, whilst some uncertainty may remain as to the effect of nuclear spin on other substances, no reasonable doubt exists as to the value of the entropy of hydrogen.

Light Intensity of a Quartz Mercury Lamp

DR TSUNESABURO ASADA, of the Shiomi Institute of Physical and Chemical Research, Osaka, Japan, has sent us an interesting communication describing measurements he has made on the intensity of the light emitted by a quartz mercury lamp The instantaneous values of the light intensity at several points of the luminous part of an alternating current quartz mercury lamp, the terminal voltage, and the current were all measured by the help of an

FIG 1 FIG 2

oscillograph In carrying out the test, the image of the lamp was projected by means of a lens on to a screen

The intensity of the light on each part of the image was found by a vacuum cæsium photoelectric tube The photoelectric current was first amplified by a triode, which was found to give no deformation of the shape of the current wave

In Fig 1 an oscillogram is shown of the current I_c flowing in one of the anodes C and the terminal voltage V_{ac} across it This oscillogram shows clearly that so long as there is an appreciable current through the electrode, its terminal voltage is practically constant

Fig 2 is an oscillogram of the current I_c and the intensity of the light G_c in the neighbourhood of the anode C From these two oscillograms it is concluded that so long as the terminal voltage is constant the intensity of the light emitted is directly porportional to the current

A special direct current mercury lamp was made of transparent fused quartz which could be used at various current densities The light intensity of the lamp was measured by a monochrometer and a vacuum photoelectric tube It was found that the relation between the intensity of the light G, the current I, and the potential difference V between the anode and the cathode could be expressed by a formula of the form

$$G = kI(V - V_0)^n$$

where k and V_0 are constants

V_0 is the least potential difference between both the electrodes required to maintain the arc, and is a constant for a given lamp For a given wave length, the number n is constant

It was found by plotting curves having log (G/I) as ordinates and log $(V - V_0)$ as abscissæ that, provided the potential difference was not very small, the resulting curve was a straight line The formula is an experimental one It shows that when the temperature of the mercury vapour is raised by increasing the terminal voltage, the radiations of longer wave-length increase much more rapidly than those of shorter wave length This radiation, therefore, follows quite a different law from black body radiation

Experiments with the alternating current mercury lamp show that the formula given above still holds, provided we take the mean value of the light intensity, the effective potential difference between one of the anodes and the cathode, and the effective value of the input current The value of n, however, is different from that for the direct current mercury lamp

Marine Biology in Madras and Ceylon

THE Administrative Report for the year 1928–29 of the Madras Fisheries Department, by Dr B Sundara Raj, Director of Fisheries Madras (Report No 1 of 1930, *Madras Fisheries Bulletin* vol 24, 1930), embraces a large variety of subjects Part 1 describes the activities of the Department, including marine and estuarine fisheries, inland food fishes, pearl and chank fisheries, biological specimen supply, anti malarial and socio economic work, and fish industries Part 2 deals with finance, Part 3 with staff and equipment, with various appendices The importance of investigation relating to food fish is emphasised as being the primary object of a scientific department of fisheries It is evident that here great difficulties are encountered from lack of proper accommodation and staff, nevertheless, it is shown that progress is being made Research on marine fisheries was undertaken by the trawler *Lady Goschen*, and on three shore stations at West Hill (Calicut), Krusadai Island, and Vizagapatam, the first two stations being provided with small laboratories, and at the Madras Aquarium laboratory work is being done on the early stages of the edible oyster Survey of fishing banks and experimental trawling was carried on, including extensive cruises from Mangalore to Cape Comorin, fishes and certain invertebrates were identified and plankton collections made So far only the otter trawl is used for fishing The Danish seine could not be employed, as the motor boat originally intended for the purpose was condemned as too old for the open sea Proposals have been made to the Government for the purchase of a small motor boat, and a drift net and long lines for surface fishing are ordered

Investigations in the Collair Lake on the prawn *Peneopsis monoceros*, the "Chakku Royya", were continued, but still little is known about the breeding grounds of this commercially important crustacean. Again the absence of staff for this work is to be regretted Deep water tank fishing in the Mopad Reservoir was satisfactory, a backwater net from Ennore, drift nets, and long lines being used with good results Fish breeding and stocking experiments appear to have been unsuccessful for various reasons Pearl oysters still continue to make sudden appearances and disappearances It is proposed to undertake extensive research connected with this subject when the Krusadai Biological Station is instituted, meanwhile regular inspection of the pearl banks goes on, and any spat falls will be noted

The Fisheries Training Institute, Calicut, provides courses of study in the elements of navigation and handling of sailing boats, with classes in fish-curing, and pupils are on the increase

The Administration Report of the Marine Biologist of Ceylon for 1929 (Part 4—Education, Science, and Art (G) July 1930), by Dr Joseph Pearson, contains information on the pearl fishery, Gulf of Manaar, the window pane oyster fishery and chank fisheries, with fishery statistics, report of the second assistant marine biologist and of the marine superintendent

The year 1929 was unfortunate for several reasons, and the absence of Dr Pearson made it necessary to abandon the inspection of the new paar which was discovered in the region of Twynam's Paar, and which in the previous February and March was densely covered with oyster spat for a considerable part of its area of some 30 square miles The usual survey of the Pedro and Wadge Banks was also abandoned.

In November, however, a portion of the area off Chilaw was examined by a running survey by dredge for the purpose of charting the paar area, and a chart is given with the present report In this charting no idea can be given of the number of oysters present, but a picture is provided of the general limitations of the paar ground and the general slope of the area It also shows the nature of the paar and will indicate the presence of oysters, although small patches of oysters may be missed Current observations on the main Pearl Banks were continued. There is a westerly trend in all currents which would tend to take all pelagic oyster larvæ present when the observations were made out into the deep water, where they would be lost

Dr Pearson has obtained all particulars for a new boat to take the place of M L *Lion*, which has been condemned The new boat is to be of the modern Scotch type of fishing boat, with a length of 45 feet, beam 13 feet 6 inches, draught 5 feet 6 inches

Afforestation in New Zealand.

THAT private companies have been formed in New Zealand to promote afforestation work is well known Many of these companies have now been federated into the New Zealand Timber Growers' Association, which publishes an official quarterly known as the *Timber Growers' Quarterly Review*, the second number (for September last) of which has recently appeared This number deals primarily with reports, etc , of the 1930 Conference of the member companies of the Association

The attitude of the companies towards this new national industry and the aims and objects of the latter are well portrayed and merit a close study in Great Britain The member companies in the Association now represent a combined capital of £5,000,000 " Afforestation in a minor way ", it is truly said, " is practically useless and would really mean nothing whatever either to New Zealand or the Empire , and although the companies represented in the Association to day have joint afforestation schemes in hand comprising over 250,000 acres, the desired objective is a million acres of exotics " The magnitude of the task can be readily appreciated, as also the value of combining

The delegates to the Conference had the opportunity of meeting the Prime Minister, Hon G W Forbes, who has recently been at the Imperial Conference in London, and the Minister responsible for the N Z Forest Department, the chief matter under discussion being the important one of future co operation in research work Here the Association is taking the broadest views The president, Mr W Fraser, in discussing the question with the Minister, pointed out that while the Association "had planned in the first instance to establish its own arms of research, the successful functioning during the past 12 months of the Biological Committee, to which not only the Association but also the Bureau of Scientific and Industrial Research, the Cawthron Institute, the Sawmillers' Federation, and the Forestry Department had contributed brains and money, had indicated the possibility of still further co operation in matters that are equally of joint interest and joint advantage "

The New Zealand Timber Growers' Association is said to consist largely of business men who may be regarded as trained executives and organisers It also embodies technical forestry men of wide and sound experience and established judgment It regards research as being a most important and vital adjunct or partner of business, and is prepared to forward energetically and substantially to endow useful research along business lines in the interests of afforestation This was the message of the 1930 Conference

There was no attempt on the part of the Conference to minimise the value of the work (much of it of an experimental nature) of the State Forest Service during the past quarter of a century Far otherwise But the importance of the provision of a large volume of softwood timber, which it has been shown can be grown on large areas of available land, has been fully realised , also that this work, to be done expeditiously, is a purely business proposition, quite outside the capacity of a State Department, which could not be granted the funds from the public purse to carry it on with such rapidity

The realisation of this fact and the coming of the private companies, run on investors' capital, is remarkable and furnishes evidence of a shrewd foresight on the part of the New Zealanders Not less remarkable, if we compare it with the reduplication of research work in different institutes and so forth in Great Britain, is the swift recognition by the leaders of the Association that co operation in research with the existing centres would be the most practical step to take, instead of bringing into being new and independent ones

Archæological Investigation in Oregon, U S A.

RESULTS of archæological investigation on the middle Columbia River undertaken by the University of California in 1924–26 are recorded by W D Strong, W E Schenck, and J H Stewart in the University's *Publications in American Archæology and Ethnology*, vol. 29, pt 1, under the title "Archæology of the Dalles-Deschuttes Region" This area was chosen for investigation as the geographical and economic conditions at this point of the river are such as to have made it one of great importance to primitive man, and it must have been occupied from a remote period.

Seven distinct types of evidence were exposed, these including the Wakemap Mound, village sites on Miller's Island, burials—cremation and pre- and post-Caucasian inhumations—as well as numerous petroglyphs Of these, the most important were the mound, on account of the depth of the deposit containing evidence of occupation, and the cremation burials, on account of the richness of their culture It was noted that the culture of the cremation burials was quite distinct in character from that of the mound, the former being of an entirely ceremonial and ornamental character, while the objects from the mound were entirely utilitarian On the whole, however, there was good reason to think the two are connected, and to regard them as representing two sides of a single culture It is also suggested that the old type conical, semi subterranean house is connected with the mound culture, but that connexion is not yet proved

It seems probable that most of the rock carvings are to be associated with the mound and cremation culture, most of them being attributed to the Wakemap people There is a lack of relationship between the post-Caucasian burials and the mound and

cremation culture, but some can be assigned to the Sahaptin The relationship of the pre Caucasian burials at the upper end of Miller's Island to the Wakemap culture is not yet clear

The general conclusion as a result of the investigations seems to be that the earliest comers to this region possessed a culture, already well developed, which was basically Salish After a long period it was gradually modified by coastal influence, very probably through Upper Chinookan tribes, but also probably from the centre of Washington This is manifested principally in the art, which combined the plateau and coast styles to produce a local style, expressed in the petrography and the ground and sculptured stone work The ultimate fate of the Wakemap and cremation culture is unknown, but the continuity of Salish culture was broken by the Sahaptin and Waiilatpuan migrations The Dalles Deschuttes Salish disappeared They may have been absorbed by the Wasko and Wishram

Malayan Medicine

THE two publications on Malayan medicine, referred to in NATURE for June 7, p 862, have now been supplemented by "The Medical Book of Malayan Medicine" (*The Gardens' Bulletin*, Straits Settlements, 1930, vol 6, part 3), edited by Dr J D Gimlette and Mr I H Burkill

In 1928 the attention of the two editors was directed to a manuscript in the possession of the Pharmaceutical Society, entitled "This is the Medical Book of Malayan Medicine" The history of the manuscript has been lost, but the editors, from their expert knowledge of the subject, have been able to suggest that the original document, of which this manuscript is a translation, made by a *munshi* (teacher of languages) named Inche' Ismail, consisted of a series of notes on diseases and the prescriptions necessary to cure them, made by a native practitioner, probably resident in Penang The compiler seems to have allowed a British official in Malaya to have the notes translated by Ismail, possibly with the view of the translation forming part of the collections assembled in the Straits Settlements for display on behalf of that Colony at the Colonial and Indian Exhibition held in London in 1886

The manuscript, corrected and edited, is now published with Dr Gimlette's diagnostic notes of the diseases which appear to be indicated by the Malayan practitioner's descriptions of symptoms, and with Mr Burkill's determinations of materia medica There are 543 prescriptions in the book, ranging from a village simple such as the juice of a banana tree, used for a disease which, judging from the symptoms, Dr Gimlette thinks, may be either rheumatic or dengue fever, up to No 289, in which a concoction of 29 drugs is prescribed for anointing the body in cases of smallpox This is not a record for poly pharmacy, for *Confectio Damocratis*, supposed to have been invented by Mithridates the Great (born 134 B C), contained at least 44 ingredients, and had a great reputation in the Middle Ages as a prophylactic against the plague

Modern medicine is not likely to reap any considerable benefit from the labours of the two learned editors, but this, like the two previous publications in the same series, is of great interest and importance as a contribution to the history of the development of medicine In this connexion special mention should be made of the glossary of Malayan names for drugs and diseases, which is arranged as part of the excellent index to the volume

University and Educational Intelligence.

CAMBRIDGE —The Faculty Board of Physics and Chemistry have reappointed Dr J Chadwick, of Gonville and Caius College, assistant director of radioactive research at the Cavendish Laboratory

The prize of £30 from the Gordon Wigan Fund for a research in chemistry in the year 1930 has been awarded to P S H Henry, of Trinity College, for a dissertation entitled "The Experimental Determination of the Specific Heats of Gases"

Two new professorships have been established by Grace of the Regent House One is in geography, and the first holder will be Mr F Debenham, of Gonville and Caius College The other is in experimental psychology, and the first holder will be Mr. F. C Bartlett, of St John's College

LONDON —The Julius Mickle Fellowship was awarded to Dr C H Andrewes for 1931, for his research work on viruses

OXFORD —On Feb 3 Congregation passed a decree accepting the offer of the Forestry Commission and the Secretary of State for the Colonies to make contributions at the rate of £5000 a year as from March 1929 to July 1931 to the maintenance of an Imperial Forestry Institute in Oxford, the University undertaking to make during the same period contributions to the Department of Forestry at a rate not exceeding £300 a year in addition to its current contribution Mr C G Morison, in proposing the decree, explained that it is a renewal of a former decree The Institute, which has now been in existence for about five years, is active in research and in giving post graduate instruction The relations between the Institute and the University are at present engaging the attention of Council

A COURSE of lectures on "Dielectrics" will be delivered at the Northampton Polytechnic Institute, St John Street, E C 1, by Dr L Hartshorn, on Mar. 4, 11, 18, and 25 They will deal with the phenomena of leakage, absorption, power losses in alternating fields, dielectric strength, and so on, and will be especially addressed to those concerned with the manufacture and industrial applications of insulating materials

MR A T STARR has been appointed to the staff of Faraday House Electrical Engineering College, London Mr Starr took the London B Sc, with first class honours in mathematics, in 1925, receiving also the Lubbock Prize At Cambridge he obtained a major scholarship at Corpus Christi College, took a first class in both parts of the Mathematical Tripos, and received honourable mention in the Smith's Prize examination For the past three years Mr Starr has been working in the laboratories of the International Telephone and Telegraph Company

A CONFERENCE on "Changing Education in an Old Empire", organised by the New Education Fellowship, will be held at Bedford College, London, on July 24 30, under the presidency of Sir Percy Nunn Mr K Lindsay is the honorary secretary, to whom all communications should be addressed, c/o New Education Fellowship, 11 Tavistock Square, London, W.C 1. It is hoped that the Conference will lend support to the project of establishing in London a permanent educational institute to act as research bureau and central clearing house of educational ideas for the Empire.

Birthdays and Research Centres.

Feb 12, 1872 —Prof A J EWART, F R S, professor of botany in the University of Melbourne

The chief investigation I have now in progress is an attempt to produce graft hybrids between species of Eucalyptus, which I have been working on for more than ten years Another problem in hand is in regard to the influence upon animals of the prolonged ingestion of plants containing saponin

Feb 16, 1848 —Prof HUGO DE VRIES, For Mem R S, formerly professor of plant anatomy and physiology in the University of Amsterdam

My chief investigation now in progress is on the inheritance of characters of new mutants of *Œnothera Lamarckiana*

A subject to which I think attention might usefully be given is the difference and analogy between phylogenetical and explosive mutability

Feb 17, 1884 —Prof JOHN READ, professor of chemistry in the United College of St Salvator and St Leonard, University of St Andrews

The endowed chemical research laboratories at St Andrews have accommodation for about sixteen research workers, apart from members of the staff, and as a rule this is fully utilised Most of the numerous publications which have appeared from this organic chemical school during the last twenty-five years have been concerned with the chemistry of sugars and the more complex carbohydrates, stereochemical problems also have been studied

My students have continued the stereochemical tradition, in publications upon such subjects as the optical resolution of simple asymmetric compounds and stereochemical relationships in the hydrobenzoin series A second series of investigations deals with the formation of halogenohydrins from unsaturated compounds Our chief field of work, which maintains the traditional interest of the school in natural organic products, is the systematic chemical and stereochemical study of menthols, menthones, piperitones, phellandrenes, carvone, and related substances derived directly or indirectly from essential oils of plants We are interested also in the biochemical origin and ancestry of these substances In my opinion, results of great biochemical value would attend systematic collaborative work between organic chemists and botanists in tracing the chemical effect of hybridisation, as evidenced, for example, in the composition of essential oils in a suitable genus such as *Eucalyptus*

Feb 17, 1890 —Dr R A FISHER, F R S, head of the Statistical Department, Rothamsted Experimental Station, Harpenden, Herts

The great event of our generation for the progress of the human mind is, I believe, the development of a comprehensive and rational theory of inheritance If this 'mystery of mysteries' is capable of a simple and definite formulation, need any biological problem, however complex, be regarded as incapable of exact treatment?

The new knowledge has so far had no appreciable effect on the means whereby practically important improvements are made in domesticated animals and plants The characters which confer value are always quantitative and depend upon the cumulative effects of numerous separable factors Selection of favourable combinations as practised from time immemorial by breeders, such as Chevalier or Burbank, is still the only effective method What is needed, and seems now practicable, is the quantitative evaluation by extensive measurements, combined with systematic mating, of the selective possibilities of the populations available for selection This is an almost untouched field and will remain so so long as genetics and biometry are mutually exclusive studies

Feb 26, 1864 —Mr JOHN EVERSHED, F R S, lately director of the Kodaikanal and Madras Observatories

The main objects of my present research are to determine the solar rotation at high levels, and the general shift towards red of the calcium, hydrogen, and iron lines Previous work here has shown that prominences give a daily angular speed of rotation about 3° in excess of that given by the reversing layer I shall attempt to determine whether this excess holds throughout the sunspot cycle, or is connected with sunspot frequency

My measures show that the shift of the lines *H* and *K* towards red exceeds the Einstein effect, both in prominences and chromosphere, by 0 007 A, and iron lines at the limb in the same spectral region give nearly the same excess The cause of this 'limb effect' is a mystery, and measures of solar spectra will be continued in the hope of throwing new light on the problem

Societies and Academies.

LONDON

Royal Society, Feb 5—C F Jenkin The pressure exerted by granular material A model consisting of a rectangular frame holding a single layer of steel discs was made which reproduces the leading phenomena observed in sand, particularly the effects of 'arching' The solutions are found for the forces exerted by the discs under a number of different conditions, including three typical examples of arching In the light of these results, an apparatus was designed for measuring the pressure of sand on a retaining wall in which *end arching* was eliminated The most important new result obtained is that the centre of pressure may be very much higher than was supposed, and that the pressure distribution on the wall is quite different from the triangular distribution commonly assumed —F L Arnot The diffraction of electrons in mercury vapour An investigation of the angular scattering of electrons in mercury vapour over an angular range of from 18° to 126° is described Results are shown for fifteen different velocities of the primary beam between 8 and 800 volts All the scattering curves show distinct maxima and minima, maxima of four different orders being obtained The absolute scattering of 82 volt electrons between 15° and 60° has been redetermined —S Rama Swamy On the transmission of light by thin films of metal Quantitative observations on the transmission coefficient of metal films for different wave lengths of light in the visible range and its changes on heating the films are described and discussed Thin films of gold and silver, obtained by cathodic sputtering, were heated in a furnace and their absorption spectra photographed at different temperatures, a pointolite lamp being the source of light The transmission coefficient was deduced from the photometric measurements of the spectrograms —D C Colbourne The diurnal tide in an ocean bounded by two meridians The diurnal tide is considered in an ocean on a rotating globe bounded by two meridians 60° apart and of uniform depth 12,700 ft The solution of the general dynamical equations of the tides satisfying the required conditions is obtained by the introduction of a null function according to the method developed by

Goldsbrough By means of this solution the tidal amplitudes and phase angles at numerous points have been calculated Amplitudes of the diurnal tide are considerably smaller than those of the semi diurnal tide, and the range of values obtained for the phase is unusually limited

Linnean Society, Feb 5 —Miss S Finnegan Brachyura collected by Dr Crossland on the *St George* Expedition to the Pacific, 1924–25 Sixty five species of crabs were collected, of which eight are new, and one new variety is described In addition, the opportunity has been taken to analyse all the existing records of Brachyura from the region in question, and to attempt to identify the various geographical elements in the fauna The chief conclusions are that certain genera may be regarded as typically American So far as the scanty geological evidence goes, these genera do not date further back than the Pliocene There is evidence that the similarity between the Indo Pacific and Panamic faunas was greater in the past that it is to day

DUBLIN

Royal Irish Academy, Jan 26 —G H Nall Irish sea trout This paper deals with the results obtained from the examination of some 2200 samples of scales taken from sea trout from ten river systems in the west of Ireland The average age rate of growth, age at migration and at first return from the sea to spawn, the number of spawning marks, etc , are determined and comparisons made with similar results obtained from the examination of sea trout scales in various rivers in Scotland The chief characteristic of the sea trout from the west of Ireland rivers which emerges from this study is the relatively small size attained The average duration of life is comparatively short The proportion of sea trout which returns to the river, after only a short stay of a few months in the sea, is high It is suggested that some of the rivers are deficient in food for the large numbers of fry which are present The low growth rate during sea life is possibly due to the absence of rich feeding grounds adjacent to the mouths of the various rivers

CRACOW

Polish Academy of Science and Letters, Nov 10 —W Kapuschinski The fluorescence of zinc vapour The saturated vapour of zinc, excited by ultra violet light, gives a fluorescence spectrum containing lines and bands Details of the study of this spectrum are given —**L Orkisz** The final orbit of the comet 1925, 1 (Orkisz) The elements given are based on observations made between April 5, 1925, and May 12, 1926 —**K Dziewonski, B Grünberg, and Mlle J Schoenowna** Researches on the acenaphthene sulphonic acids —**S Kozik** Two chlorites in veins from Haute Tatra These chlorites occur in veins about 2 cm thick in granite, their composition is quite different from that of the granite —**F Bieda** Remarks on the nomenclature and classification of certain species of Nummulina (1) —**J Zerndt** *Triletes giganteus*, a huge megaspore found in coal This spore has been found in coal from nearly all levels of Polish coal strata It measures 6 4 mm in diameter and is the largest megaspore known —**M Kostowiecki** The relation between Hassal's corpuscles and the neighbouring blood-vessels in the thymus of the human fœtus

SYDNEY

Linnean Society of New South Wales, Nov 26 —O H Sargent Xerophytes and xerophily, with special reference to protead distribution The author records observations on the distribution of Proteads in Western Australia, particularly in its relation to soil conditions and rainfall He details experiments in estimating the water needs of a few species, and also in estimating the degree of transpiration by the two types of leaf (broad leaves and needles) found on *Hakea trifurcata* —**W L Waterhouse** Australian rust studies (3) Initial results of breeding for rust resistance Following upon specialisation studies of *Puccinia graminis tritici* in which it was shown that prior to 1926 two groups of forms, namely, (1), 43, 44, and 54, and (2), 45, 46, and 55, were present in Australia, breeding for complete resistance was undertaken Many commercial varieties behave reciprocally to these two groups The inheritance of resistance was traced in the cross between these, as well as between other varieties Resistance is dependent upon a single dominant factor in these varieties —**I A Brown** The geology of the south coast of New South Wales (3) The Monzonitic Complex of the Mount Dromedary district The main intrusion probably assumes a laccolithic form A number of rare rock-types are included Detailed petrographic descriptions of the various types are given, and these are compared with rocks in other parts of the world The mineralogical and chemical evidence of consanguinity of a number of types supports the field evidence of the comagmatic origin of the monzonitic types The possible origin of the nepheline bearing and garnet bearing rocks is considered, and is compared with that of similar occurrences at Magnet Cove, Arkansas, the Fen District, Norway, and elsewhere —**G Carey** The leaf buds of some woody perennials in the New South Wales flora Leaf buds in New South Wales are divided into three classes (*a*) scaly, (*b*) intermediate, and (*c*) naked A great variability of bud types is shown among genera of any one family, and among the species of a single genus The evidence points to the fact that bud structure and development are influenced by the physiology of the shoot —**H L Jensen** Notes on a cellulose decomposing soil fungus of an unusual character A fungus, probably belonging to the genus *Botryosporium*, was isolated from an English field soil with addition of manure This organism proved very sensitive to acid reaction, *p*H 4 5 being very near the limit of acidity at which growth could be induced, a good growth would only take place at *p*H values above 6 0, and an optimum zone seemed to stretch from *p*H 6 6 to *p*H 7 4 and possibly higher In neutral or alkaline solution the fungus exerted a very strong cellulose decomposing activity, in unbuffered physiologically acid solution almost none Its sensitiveness to acidity is greater than that of any fungus hitherto studied in this respect

VIENNA

Academy of Sciences, Oct 16 —E Beutel and A Kutzelnigg (1) Analysis by luminescence —(2) Luminescence of painter's white colours and application of analysis by luminescence to the investigation of paintings —(3) Observations in the alkaline earth group and numerical criteria of luminescence —**A Haas** A relation between the radial velocity of spiral nebulæ and the disintegration velocity of matter —**K Lehnhofer** Deformities in species of *Sapphirina* —**F Halla** Röntgenographic distinction between magnesite and dolomite —**A Deseyve** Secondary corpuscular radiation released from light elements by α rays The disintegration of silicon and phosphorus with α-particles from polonium seems new (See Radium Institute Circular No 267.)—**E Tschermak** (1) New observations on the fertile hybrid *Triticum turgido-villosum* —(2) Xenia in Leguminosæ Several cases of apparent direct action of foreign pollen on colour and form of seeds.—

E Dittler and H. Lasch Synthetic researches on the formation of mixed crystals of barium and strontium felspar with orthoclase —F Raaz The structure of synthetic gehlenite, $2CaO\ Al_2O_3\ SiO_2$

Oct 23 —R Scheu Relations between tensile strength in oscillation by bending and by twisting —M Beier Zoological expedition to the Ionian Islands and the Peloponnesus (14) The slugs treated by H Wagner —K Gödel Some mathematical results on definiteness of decision and freedom from contradiction

FRIDAY, FEBRUARY 13

ROYAL ASTRONOMICAL SOCIETY (Annual General Meeting) at 5 —Presidential Addresses by Dr A C D Crommelin on the award of the Gold Medal to Prof W de Sitter and the Jackson Gwilt Medal and Gift to C W Tombaugh

BIOCHEMICAL SOCIETY (at Lister Institute), at 5 —W T J Morgan A Specific Precipitating Polysaccharide from *B dysenteriæ* (Shiga).—L F Hewitt Oxidation Reduction Potentials of Pneumococcus Cultures —B C Guha Investigations on Vitamin B_2.—E Boyland and O Meyerhof Glycogen Synthesis in Muscle Poisoned with Mono iodoacetic Acid —Gladys Bird and P Haas The Cell Wall Constituents of Laminaria. Mannuronic Acid —M G Macfarlane The Influence of Potassium Mono iodoacetate on Fermentation by Yeast Preparations —R Robison and E J King Hexosemonophosphoric Esters —W Robson and J Lamb The Erlenmeyer Synthesis of Amino acids

ROYAL COLLEGE OF PHYSICIANS OF EDINBURGH at 5 —Dr D K Henderson Social Psychiatry (Morison Lectures) (3).

ROYAL SOCIETY OF MEDICINE (Clinical Section) at 5 30

BRITISH PSYCHOLOGICAL SOCIETY (Æsthetics Section) (at Bedford College) at 5 30 —R Ellis Roberts Reality in Life and Literature

MALACOLOGICAL SOCIETY OF LONDON (Annual General Meeting) (at Linnean Society), at 6 —G C Robson Some Problems of Molluscan Evolution (Presidential Address)

NORTH-EAST COAST INSTITUTION OF ENGINEERS AND SHIPBUILDERS (at Mining Institute Newcastle upon Tyne), at 6 —W C S Wigley Ship Wave Resistance—an Examination and Comparison of the Speeds of Maximum and Minimum Resistance in Practice and in Theory

SOCIETY OF CHEMICAL INDUSTRY (Chemical Engineering Group) (at Institution of Civil Engineers) at 6 30 —D MacDonald Silver and its Application to Chemical Plant

INSTITUTION OF LOCOMOTIVE ENGINEERS (LONDON) (at 36 George Street, Manchester), at 7 —D W Sanford The Development of the Piston Valve to improve Steam Distribution

INSTITUTION OF MECHANICAL ENGINEERS (Informal Meeting) at 7

INSTITUTION OF STRUCTURAL ENGINEERS (Informal Meeting) (at Chamber of Commerce Birmingham) at 7 —S I Horolle and others Discussion on Foundations

MANCHESTER ASSOCIATION OF ENGINEERS (at Engineers Club Manchester) at 7 15 —C H Faris The Applications of Electro deposited Metal to Engineering

SOCIETY OF CHEMICAL INDUSTRY (Glasgow Section jointly with other Chemical Societies) (at Ca doro Restaurant Glasgow) at 7 30 —Prof G Barger Ergot and Ergotism

SOCIETY OF CHEMICAL INDUSTRY (South Wales Section jointly with Microscopical Society of Wales) (at Cardiff Technical College) at 7 30 —C A Seyler The Microscopy of Coal

BLACKBURN TEXTILE SOCIETY (at Blackburn Technical College) at 7 30 —S N Duguid Smoke Abatement and Fuel Economy

JUNIOR INSTITUTION OF ENGINEERS at 7 30 —H C Reid Monolith Foundations

INSTITUTE OF METALS (Sheffield Section) (at Sheffield University), at 7 30 —N C Maples The Applications of High Nickel Nickel Copper Alloys and Pure Nickel in Industry

ROYAL SOCIETY OF MEDICINE (Ophthalmology Section) at 8 30 —J H Doggart Recurrent Vascular Keratitis of Unknown Origin —Dr Ross Ford A Case of Retrobulbar Neuritis masked by Chloroiditis and due to Latent Sinusitis

ROYAL INSTITUTION OF GREAT BRITAIN at 9 —Prof F Ll Hopwood Ultrasonics Some Properties of Inaudible Sound

SOCIETY OF DYERS AND COLOURISTS (London Section) —A J Hall Bleaching Dyeing and Finishing Processes and their Effect on Finished Goods

SATURDAY FEBRUARY 14

BRITISH PSYCHOLOGICAL SOCIETY (jointly with Cambridge Psychological Society) (in Psychological Laboratory Cambridge) at 2 45 —Papers by Prof W S Hunter and Dr R S Creed —At 6 —Papers by Prof E D Adrian and Dr J T MacCurdy

ROYAL INSTITUTION OF GREAT BRITAIN at 3 —J Stephens On the Reading and Speaking of Verse (1) On Speaking Verse

LEICESTER LITERARY AND PHILOSOPHICAL SOCIETY (Chemistry Section) (at Leicester Museum) at 8 —J A Christian Modern Methods of Sewage Disposal

MONDAY FEBRUARY 16

VICTORIA INSTITUTE (at Central Buildings Westminster), at 4 30 —Dr J Knight Demon Possession in the Light of Modern Research (Dr Schofield Memorial Paper)

ROYAL GEOGRAPHICAL SOCIETY at 5 —Dr L Dudley Stamp Land Utilisation Survey

INSTITUTION OF ELECTRICAL ENGINEERS (Mersey and North Wales (Liverpool) Centre) (in Arts Theatre Liverpool University) at 7 30 —Prof W Cramp The Birth of Electrical Engineering (Faraday Lecture)

INSTITUTE OF METALS (Sheffield Section) (at Sheffield University) at 7 30 —Conjoint Discussion on Refractories for Heating and Melting Furnaces

ROYAL INSTITUTE OF BRITISH ARCHITECTS at 8 —F W Deas The Work of Sir Robert Lorimer

EUGENICS SOCIETY (at Rembrandt Hotel Thurloe Place S W).—Sir J Arthur Thomson Warnings from Nature (Galton Lecture)

TUESDAY FEBRUARY 17

ROYAL INSTITUTION OF GREAT BRITAIN at 5 15 —Sir William Bragg Recent Experimental Physics (2) The Sizes of Atoms

ROYAL STATISTICAL SOCIETY (at Royal Society of Arts), at 5 15 —D Caradog Jones The Social Survey of Merseyside

ROYAL SOCIETY OF MEDICINE at 5 30 —General Meeting

ZOOLOGICAL SOCIETY OF LONDON at 5 30 —H C Wilkie The Middle Ear of the Horse (*Equus caballus*).—M K Serebrennikov On the Polychromatism and Albinism of the Siberian Squirrels —W S Bristowe (a) A Contribution to the Knowledge of the Spider Fauna of South West Ireland and in particular the Islands off the Coast (b) The Spiders of the Island of Grassholm and some Additions to the Skomer Island List —Dr A D Misra On the Internal Anatomy of the Female Lac Insect, *Laccifer lacca* Ckll (Homoptera Coccidæ).

Royal Photographic Society of Great Britain, at 7.—J. E. Saunders: Who's Who in Two Zoos.

WEDNESDAY, February 18.

Royal Meteorological Society, at 5.—L. J. Sutton: Note on Haboobs. —Prof. S. Chapman and Miss M. Hardman: The Lunar Atmospheric Tide at Ocean Island.—A. C. Best: Horizontal Temperature Differences over Small Distances.—E. Ll. Davies: A Portable Temperature Gradient Indicator.

Royal Microscopical Society (at B.M.A. House, Tavistock Square), at 5.30.—Prof. R. Chambers: The Nature of the Living Cell, with Demonstration by Micro-Dissection, Micro-Injection, and Cinematograph.

Overhead Lines Association (at Institution of Electrical Engineers), at 5.30.—Discussion on Wayleaves.

Institution of Electrical Engineers (London Students' Section), at 6.15.—V. S. Lake, W. F. J. Walton, and others: Discussion on Are the Present Methods of Those Interested in the Supply of Current and Apparatus Conducive to the Spread of Domestic Electrification?

Institution of Automobile Engineers (Manchester Centre) (at Engineers' Club, Manchester), at 7.—E. V. Pannell: Light Alloy Piston Development.

Institution of Electrical Engineers (Tees-side Sub-Centre) (at Cleveland Technical Institute, Middlesbrough), at 7.—S. G. Brown: Loud Speakers since their Conception, with Gramophone Pick-ups and Wireless Recording Apparatus.

Illuminating Engineering Society (at Home Office Industrial Museum, Horseferry Road), at 7.—Discussion on Problems in Illuminating Engineering.—W. J. Jones: The Relation between Intensity of Illumination and Visual Capacity.—J. H. Parker: The Lighting of the Kingsway Tunnel.—O. P. Bernard: Lighting at the International Exhibition of Persian Art.—H. H. Long: Lighting for Furniture Spraying.—H. R. L. Goring: A Problem in Cathedral Lighting.—R. A. Ives: A Problem in Flood Lighting.

Institution of Automobile Engineers (Leeds Centre) (at Metropole Hotel, Leeds), at 7.15.—Dr. W. H. Hatfield: Rustless Steels as applied to Automobiles and Aircraft.

North East Coast Institution of Engineers and Shipbuilders (Graduate Section) (at Bolbec Hall, Newcastle-upon-Tyne), at 7.15.—D. Tagg: The Utilisation of Waste Heat in Oil Engine Installations.

Institution of Electrical Engineers (Sheffield Sub-Centre) (at Royal Victoria Hotel, Sheffield), at 7.30.—C. C. Paterson: Address.

Royal Society of Arts, at 8.—G. H. Jack: The Art of the Bridge Builder.

Royal Society of Medicine, at 9.15.—Dr. H. L. Tidy: Poisoners of Ancient Times.

THURSDAY, February 19.

Royal Society, at 4.30.—Prof. A. J. Allmand and L. J. Burrage: The Discontinuous Nature of the Process of Sorption of Gases and Vapours by Porous Solids.—C. H. Collie: The Decay Constant of Uranium II.—*Papers to be read in title only*:—Prof. L. N. G. Filon and F. C. Harris: The Photo-Elastic Dispersion of Vitreous Silica.—G. B. Deodhar: Some Investigations in Röntgen Spectra.—J. G. A. Griffiths and Dr. R. W. G. Norrish: The Photosensitised Decomposition of Nitrogen Tetrachloride.—Prof. S. Chapman and J. M. Stagg: On the Variability of the Quiet-Day Diurnal Magnetic Variations. II.—A. Thom and J. Orr: The Solution of the Torsion Problem for Circular Shafts of Varying Radius.—Prof. C. G. Darwin: Examples of the Uncertainty Principle.—E. C. Bullard and H. S. W. Massey: The Elastic Scattering of Slow Electrons in Argon.—V. C. G. Trew and J. F. Spencer: The Magnetic Susceptibility of Binary Systems of Organic Liquids.—W. G. Kannuluik: On the Thermal Conductivity of Some Metal Wires.—Prof. P. Kapitza: The Study of the Magnetic Properties of Matter in Strong Magnetic Fields. I., II.

Linnean Society of London, at 5.—V. S. Summerhayes: The Angiospermic Flora of the Seychelles Archipelago.—J. Ramsbottom: The 'Proceedings' of the Society of Amateur Botanists.

Royal Institution of Great Britain, at 5.15.—Prof. J. B. S. Haldane: Respiration (1).

Society of Chemical Industry (Edinburgh and East of Scotland Section) (Annual General Meeting) (jointly with Local Section of Institute of Chemistry) (at North British Station Hotel, Edinburgh), at 7.30.—C. Parkinson: Lithographic Processes and Problems.

Society of Chemical Industry (Nottingham Section, jointly with Institute of Fuel) (at University College, Nottingham), at 7.30.—J. L. Strevens: Petrographic Treatment of Coal; the Mechanical Separation of Coal into its Constituents and their Commercial Applications.

Leicester Literary and Philosophical Society (Botany and Biology Section) (at Leicester Museum), at 7.30.—P. A. H. Muschamp: The Blue Butterfly.

Institution of Electrical Engineers (Irish Centre—Dublin) (at Trinity College, Dublin), at 7.45.

Chemical Society, at 8.—F. Challenger and B. Parker: A New Method for the Preparation of Organo-thallium Halides.—W. F. K. Wynne-Jones: The Dissociation of Salts in Nitrobenzene.—D. R. Pryde and F. G. Soper: (*a*) The Formation of Acyl chloroamines from Hypochlorous Acid; (*b*) The Direct Interchange of Chlorine in the Interaction of p-toluenesulphonamide and N-chloroacetanilide.

British Institute of Radiology (at 32 Welbeck Street), at 8.30.—A Radium Symposium.—C. E. S. Phillips: Note on the Preparation of Radium Salts for Therapeutic Use.—Prof. E. N. da C. Andrade: A Model to Illustrate the Passage of an Alpha Particle in the Neighbourhood of an Atomic Nucleus.—Dr. W. Roy Ward: Some Aspects of Radium Therapy.—Dr. A. Burrows: The Organisation of the Radium and X-Ray Cancer Service in Australia.

Royal Aeronautical Society (Gloucester and Cheltenham Branch).—A. L. Williams: Heat Treatment of Steels.

Royal Aeronautical Society (Yeovil Branch).—Squadron Leader R. B. Borley: Lay-out and Equipment of Service Aircraft.

FRIDAY, February 20.

Association of Economic Biologists (Annual General Meeting) (in Botany Department Lecture Room, Imperial College of Science and Technology), at 11.30 A.M.—Discussion on Biological Races and their Significance in Evolution, to be opened by the President. Other speakers:—Dr. W. B. Brierley (Fungi), Dr. P. Bruce White (Bacteria), Dr. T. Goodey (Nematodes), Dr. W. H. Thorpe (Insects), Dr. W. B. Turrill (Seed-Bearing Plants).

Geological Society of London (Annual General Meeting), at 3.—Prof. E. J. Garwood: Presidential Address.

Physical Society (at Imperial College of Science and Technology), at 5.—G. G. Sherratt and J. H. Awbery: On the Velocity of Sound Waves in a Tube.—P. S. H. Henry: The Tube Effect in Sound-velocity Measurements.—W. A. Wood: Note on the Elimination of the β-wave-length from the Characteristic Radiation of Iron.

British Institute of Radiology (Medical Meeting) (at 32 Welbeck Street), at 5.—Dr. H. Cohen and Dr. P. H. Whitaker: Cinematograph of Ventriculography.—Dr. R. E. Roberts: (*a*) Lympho-sarcoma Involving the Stomach; (*b*) Carcinoma of Lung with Pathological Specimens.—Dr. J. H. Mather: X-Rays of a Case of Idiopathic Myositis Ossificans 1896 and 1930.—Dr. H. K. Graham Hodgson: Demonstration of the Technique of Method of Sinus Investigation.—C. T. Holland: Radiographs of Unique Conditions.

Society of Chemical Industry (Liverpool Section) (Annual Meeting) (at Liverpool University), at 6.—L. Wild: Modern Developments in Printing.

Institution of Mechanical Engineers (Annual General Meeting), at 6.—Capt. A. Swan and others: Investigation of Steels for Aircraft Engine Valve Springs.

Society of Dyers and Colourists (at Manchester Literary and Philosophical Society), at 7.—J. S. Wilson: Solazol Dyestuffs.

Royal Photographic Society of Great Britain (Pictorial Group), at 7.—Informal Meeting.

Society of Chemical Industry (Newcastle Section) (at Armstrong College, Newcastle-upon-Tyne), at 7.30.—Dr. S. R. Illingworth: Some Aspects of the Carbonisation of Coal.

Junior Institution of Engineers (at Royal United Services Institution), at 7.30.—A. J. Grant: The Construction of the Variable Density Tunnel for the National Physical Laboratory at Teddington.

Shipley Textile Society (at Shipley Technical School), at 7.30.—A. B. Shearer: Rayon: Its Uses in Woven Fabrics.

Royal Society of Medicine (Electro-Therapeutics Section), at 8.30.

Royal Institution of Great Britain, at 9.—Prof. J. B. S. Haldane: Prehistory in the Light of Genetics.

Geologists' Association (North East Lancashire Group) (at Technical College, Blackburn).—W. L. Turner: With the Geologists' Association in Czechoslovakia (Lecture).

Rochdale Textile Society (at Technical Schools, Rochdale).—Gregg: Modern Weaving Methods.

SATURDAY, February 21.

North of England Institute of Mining and Mechanical Engineers, at 2.30.

Royal Institution of Great Britain, at 3.—J. Stephens: On the Reading and Speaking of Verse (2): Difficult Poets.

PUBLIC LECTURES.

SATURDAY, February 14.

Horniman Museum (Forest Hill), at 3.30.—Major G. M. Coombs: Fiji and the Fijians.

MONDAY, February 16.

London School of Hygiene and Tropical Medicine (Public Health Division), at 5.—Col. L. W. Harrison: Venereal Disease Schemes.

TUESDAY, February 17.

University College Hospital Medical School, at 5.15.—Dr. Janet Vaughan: The Pathology and Treatment of Pernicious Anæmia. (Succeeding Lecture on Feb. 24.)

Gresham College, at 6.—W. H. Wagstaff: Geometry. (Succeeding Lectures on Feb. 18, 19, and 20.)

WEDNESDAY, February 18.

London School of Hygiene and Tropical Medicine (Public Health Division), at 5.—Col. L. W. Harrison: Venereal Disease Treatment Centres.

King's College, London, at 5.30.—H. J. Wood: The Great Age of Discovery: The Search for a Western Passage.

Belfast Museum and Art Gallery, at 8.—Prof. Gregg Wilson: The Story of a Fish.

FRIDAY, February 20.

Institution of Professional Civil Servants (at Chartered Surveyors' Institution), at 5.30.—T. Wilson: Westminster, its Palaces and Parliaments.

SATURDAY, February 21.

Horniman Museum (Forest Hill), at 3.30.—R. W. Sloley: Water-Clocks and Sun Dials.

EXHIBITION.

Tuesday, February 17, till end of April.

Exhibition of the Mineral Resources of the Empire (at Imperial Institute).

Thursday, Feb. 19, at 5.30.

Sir Robert Horne: The Mineral Resources of the Empire (Address).

SATURDAY, FEBRUARY 21, 1931

Work of the Forestry Commission. Progress and Promise *

I

THE Forestry Commission of Great Britain came into being as the result of the Forestry Act of 1919 Under the financial section of that Act, a sum of 3½ million pounds was to be provided for the first ten years of the Commission's work, the money to be voted annually by Parliament in instalments up to the total sum sanctioned for the period

The Forestry Act was based to a great extent on the advice tendered by the Acland Committee, which reported in May 1917 The Act, quite correctly as many think, did not, however, embody in its clauses the recommendations of the Committee that a hard and fast annual planting programme should be adhered to, coupled with an attempt to procure land, by purchase or otherwise, on a scale sufficient to keep pace with a planting programme laid down in advance In their review of the ten years' work, the Commissioners can state, and they do so with perhaps pardonable pride, that the two objects have been very nearly achieved, in spite of the set-back which many Government departments experienced when the 'Geddes axe' (1922) was being wielded over Whitehall Even in the case of such a department as 'Forests', a profession of the open air, we find that in 1929–30 the technical staff numbered 70, whilst clerical staff numbered 100! Unexpected difficulties also were encountered in obtaining the land required, especially in the north, and the mildest criticism on some of the areas obtained has been that the value of the forest crop they are likely to grow is problematical

Every annual report since 1923 has referred to this 'Geddes axe' contretemps in the history of the work of the Forestry Commission But to many practical foresters possessing administrative experience, the view and attitude so taken appear to be somewhat distorted It is a well accepted factor in forestry economics that any slump in trade in a country, or part of a country, will be immediately reflected in forestry revenue and returns, either of the country as a whole or in the part of the country affected, and forest officials are well aware that they will experience cuts in the expenditure side of their next forest budgets

In the case of the Forestry Commission, it is held by a not inconsiderable section of expert opinion in Great Britain that it was, and is, a mistake to tie

* Forestry Commission Tenth Annual Report of the Forestry Commissioners year ending Sept 30, 1929 Pp 69 (London H M Stationery Office, 1930) 1s 3d net

the forestry business to an annual programme of planting laid down in advance—and consequently to the necessity of endeavouring to acquire land for the purpose to at least a fixed annual amount With the finances of the country in their present position, not even the keenest supporter of afforestation in Great Britain would agree to the sacredness of either the 1929–38 planting programme or its more or less prescribed land acquisition plan

It must be admitted that the Forestry Commission deserves congratulation on its ten years' work It may be suggested, however, that the Commissioners will be well advised not to pin their faith on adhering to a hard and fast policy of *annual* planting and land acquisition, by area A clear-sighted forest administration knows full well that it has to 'cut its coat according to its cloth' Should retrenchment have to come during the present ten years, the Commissioners have now in hand a forest area of considerable size, which doubtless can provide plenty of work for the existing staff, and no one expects the present forest estate, consisting for the major part of young plantations, to show a profit for years to come—so that worry has not to be faced

It will be readily conceded, as the writer of the review in the report before us says—" The object of the ten year programme was to avoid uncertainty Uncertainty is the worst enemy of the Commissioners' work " Every forester should know that success in forestry depends upon continuity in working What, however, is not so readily appreciated is that this well recognised axiom applies to forest departments which have under their charge considerable areas of existing revenue-yielding forests Here interruptions in continuity of working result in serious losses in revenue and check the due expansion and progress of forest management Great Britain is not in such a position Therefore it would be difficult to support, on economic grounds, the necessity for adhering to a hard and fast annual planting plan, though it may be a perfectly sound policy to prepare such a scheme and endeavour to work up to it So far, the Commission has made a fetish of this branch of forest work—at the expense of reafforesting areas felled during the War, which had at least one forestry asset, an established forest soil

The work carried out under the auspices of the Commissioners up to the end of the growing season of 1929 may be briefly summarised as follows Of plantable land, 310,230 acres were acquired, of this area, 130,768 acres were planted with conifers and 7511 acres with hardwoods State-aided planting (that is, by making money grants to private proprietors) was responsible for another 76,736 acres planted The original programme did not envisage the creation of forest workers' holdings As one outcome of the unemployment question this matter was taken up in 1924 and received a warm acceptance by the Government officials concerned, the result was that 618 holdings were completed by the end of the ten year period and another 245 were in progress Wherever possible, existing buildings have been converted for the purpose of the holdings But in many cases new buildings have had to be erected and the work has proved somewhat costly However, in the case of the forest workers' holdings, there are a good many questions of an economic nature to be weighed, apart from the purely financial one So far as can be foreseen at the present time and under existing social conditions, the forest workers' holdings can be regarded as a sound departure

At the end of September 1930 the Forestry Commission had under its charge 602,000 acres of land, of which 251,000 acres had been acquired by purchase, 231,000 acres by long lease or feu, and the balance, approximately 120,000 acres, consisting of Crown Woods, had been transferred to the Commissioners under the Transfer of Woods Act of 1923 The following extract from the report will indicate that sound views now prevail on the subject of land acquisition

"In acquiring land the Commissioners have kept constantly in view their main functions, which are to establish forests and forest workers' holdings The acquisition of assets surplus to those requirements has been avoided so far as possible, and where it has been necessary to acquire surplus assets in order to build up desirable forest properties the policy is to dispose of them as rapidly as sound business permits "

The activities of the Commissioners in the direction of forest education and research work are discussed at length Expert opinion in Great Britain is by no means agreed either as to the value of some of the Commission's activities in these directions or the soundness of some of the advice given by the Commissioners References have already been made to such matters in our columns, the points in question, moreover, are well known to those interested in these matters throughout the country and need no further emphasis here

Weighed dispassionately, however, the consensus of opinion will be that the Commissioners in the work of the past ten years have deserved well of their country and have earned the thanks of their countrymen The chairmen have been Lord Lovat,

one of the originators of the scheme (1919–27), Lord Clinton (1927 to 1929, end of ten-year period), Sir John Stirling Maxwell, the present chairman Mr R L Robinson has been the Technical Commissioner throughout the period

The summary of the ten years' work is unfortunately drawn up on the most approved Whitehall lines It bristles with statistics and tabular statements, resembling a report emanating from the Treasury or Board of Trade From the point of view of the public the report is useless Several of the reports of forestry departments issued in other parts of the Empire are nowadays human documents, often illustrated The Commissioners have missed a great opportunity for propaganda to interest the public, whilst they would have set an example which might have had the beneficial result of brightening up Whitehall reports and Blue Books generally

Concepts of Social Biology

The Biological Basis of Human Nature By Prof H S Jennings Pp xviii + 384 (London Faber and Faber, Ltd, 1930) 15s net

ALMOST everything which has been written on the biological foundations of human society is based upon a false antithesis with a historical background, which should be evident to everyone who is familiar with the progress of animal biology during the last century Before the emergence of the cell doctrine during the 'thirties, Kölliker's discovery that the sperm is produced by the transformation of a single cell in the testis of the male parent, and the elucidation of the phenomenon of fertilisation by Fol in 1879, the prevailing biological concept of inheritance was very much like the legal one While the egg was still regarded as an adult in miniature, it was natural to think that we pass on our noses in much the same way as we pass on our mortgages When the essential features of fertilisation were established, it was natural that biologists should challenge the legal view of inheritance associated by custom with the name of Lamarck Had Weissmann confined himself to this modest task, his influence on biological theory would have been one of permanent usefulness Unfortunately, he could not stop at that From a total misconception of the rôle of the external environment in relation to the materials of inheritance, biological doctrine swung over to a total neglect of the rôle of environment in the process of development

Weissmann's conception of development, elaborated in association with Roux, reduced the external medium to a perfect vacuum As in Stevenson's fable, the gyves were firmly riveted on the left leg before the ulcer on the right had healed To-day the progress of experimental embryology has relegated Weissmann's theory of development and the hypothesis of germinal selection to the same limbo as the Lamarckian doctrine In animal biology, heredity and environment are used as classifications of two types of variables which interact at every stage of development, to produce at the end of the process one of a large number of possibilities called an individual Heredity includes the class of variables which can be defined in terms of the material of which the sperm and egg are respectively composed Environment includes that whole class of variables which are significant in the further development of the fertilised egg A difference between two animals may be predominantly a genetic or predominantly an environmental one To speak of characters as hereditary or environmental, innate or acquired, is, strictly speaking, meaningless

In animal biology these are commonplaces Unfortunately, in human affairs they are still startling and almost revolutionary ideas The main concern of Prof Jennings in "The Biological Basis of Human Nature" is to see that they shall become commonplace in social biology He has performed this signal service with the lucidity, good humour, and terseness which have enhanced his reputation as one of the most penetrating and provocative thinkers in contemporary biology "A burden of concepts and definitions", he says, "has come down from pre existing days, the pouring of the new wine of experimental knowledge into these has resulted in confusion And this confusion is worse confounded by the strange and strong propensity of workers in heredity to flout and deny and despise the observations of the workers in environmental action, the equally strange and strong propensity of students of environmental effects to flout and despise the work on inheritance" On behalf of the workers on heredity, it may be pointed out that extravagant dogmatism concerning the hereditary significance of human differences is less common among biologists than among statisticians, retired majors, and clergymen with journalistic propensities The leading geneticists, and among them first and foremost T H Morgan himself, have usually shown extreme reserve in discussing the genetic aspect of social behaviour

"The Biological Basis of Human Nature" does not set out to be a comprehensive text-book of

social biology It is the prolegomena to any genuinely biological analysis of human society The *Corpus errorum biologicorum* in Chap ix should be read by everyone who has an interest in the relation of biological concepts to social science Throughout the book Prof Jennings emphasises the need for detachment and scepticism in approaching what is still a virgin field of inquiry He discusses the possibilities of eugenic measures with a moderation and sanity which will compel the sympathy of many previously alienated by the manifest political bias or ludicrous exaggerations of propagandists determined to damage their own case Having stressed the extreme difficulty of analysing social differences to which several gene mutations make a contribution, he states

"We must know more as to what human troubles are due to definite single-pair gene defects These are the defects with which eugenic measures can effectively deal, and as yet but a small number of them are positively known The great difficulty about this is that bad living conditions often produce the same kind of results that bad genes do Persons may become idle and worthless, insane or criminal or tuberculous—either through bad genes or through bad living conditions, or through a combination of both So long as living conditions are bad, we do not know what ills are due to bad genes We must therefore correct the bad living conditions, not only for their directly beneficial effect, but also for the sake of eugenics When this is done, it will be possible to discover what defects are primarily the result of defective genes, and then to plan measures for getting rid of these genes measures for stopping the propagation of their carriers"

In the chapter on race mixture and its consequences the author maintains the balance between two conflicting sources of bias with judicious restraint in most of the conclusions he states The reviewer is of the opinion that he attaches too much importance to the conclusions stated by Davenport and Steggerda at the conclusion of their monograph on "Race Crossing in Jamaica", and too little weight to the actual data contained in the text Indeed, he himself departs from the high standard he has set elsewhere, when he states that the blacks "showed superiority in Mental Arithmetic and in following complicated directions for doing things On the other hand, the Whites showed a distinct superiority in the tests of intellectual ability" In the Army Alpha tests the blacks excelled in one half and the whites in the others The former category included all the numerical tests—simple or otherwise It is not clear why the verbal tests should be classified as 'intellectual' in contradistinction to the numerical tests Few biologists seem to be aware that the most recent investigations on the I Q of foster children and twins show how little justification there is for the belief that such tests distinguish differences which are of genetic and extrinsic origin The implications of Spearman's work alone necessitate a very sceptical attitude to earlier views concerning the genetic status of psychological tests

Those who are familiar with "Prometheus" will not be surprised to find that Prof Jennings stresses the need of recognising that man has a natural history of his own In the last chapter he attributes the neglect of the specifically human characteristics of human behaviour to the mechanistic tradition in the philosophy of the organism, and favours the emergent point of view as a more sympathetic setting for a humanism which draws its inspiration from biological knowledge His statement of the emergent point of view is so carefully pruned that most biologists with a mechanistic bias will find it difficult to realise why Prof Jennings goes to so much trouble to identify his own clear and unexceptionable views with what has now become a label for various species of contemporary philosophical obscurantism It is doubtful whether the disposition to interpret the entire panorama of human history within the framework of our present biological hypotheses is generally associated with an explicitly materialistic bias in philosophy or a partiality for physico-chemical interpretations of vital phenomena A consistent mechanist will be the first to recognise that the biology of Darwin's generation was neither sufficiently adequate to undertake an analysis of the structure of human society, nor even equipped to state, as we now can state, the fundamental requirements of the problem in biologically significant terms The assumption that human nature is the product of heredity and environment owes its plausibility to the mechanistic point of view and this assumption is accepted as axiomatic throughout Prof Jennings' book

An Introduction to Plato

The Growth of Plato's Ideal Theory an Essay By Sir James George Frazer Pp xi + 114 (London Macmillan and Co, Ltd, 1930) 7s 6d net

THE little book before us is far the best introduction to the study of Plato which we know, and every reader will be grateful to Sir James Frazer for rescuing it from his pigeon-holes. It was written fifty years ago as a dissertation for

fellowship at Trinity, and has therefore all the harm of youthful enthusiasm and newly acquired nowledge This more than compensates for any orrections necessary in minor points—the dating of the dialogues and so forth It is one of the book's outstanding merits Another is that, taking one thread—the development of the ideal theory—as the clue, it is possible to connect all the dialogues by their most vital link and give both unity and evolution to the picture without overloading it with details

The last, and to a scientific reader the most weighty, merit is that the author, while enjoying Plato to the utmost as a writer, a dramatist, and a poet, is under no illusions as to the fundamental fallacies of the Platonic ideas The criticism, based on a simple but very careful examination of the language of Plato himself, establishes the fact that the ideal theory arose from the questioning of Socrates as to the nature of general ideas, especially of a moral kind, was then elaborated into an ontological construction in a middle period, represented chiefly in the "Phaedo" and the "Republic", and was dispersed, by virtue of its own contradictions and a strong admixture of Pythagoreanism, in the last period, represented by the "Timaeus", the "Sophist", and the "Parmenides"

It is this sketch of the whole series of the dialogues, linked up by the ideal theory, which gives the book its high interest and value By slight enlargement here and there it can be regarded not only as an introduction to Plato but also as a picture of the nature and development of Greek philosophic thinking as a whole One point on which Sir James Frazer is most emphatic throws a flood of light on the subsequent history of Platonic idealism and its influence on Christian and modern thought He makes it abundantly clear that Plato never contemplated an idea of evil or evil things The model which was laid up in heaven was of heavenly things, and was at every stage permeated by the notion of perfection in the moral rather than the logical sense Its connexion on these lines with Christian theology is obvious, and it brings us direct to the modern conception of 'values'

On the other side the author has little trouble in making the true and obvious connexion with the weakness of Greek scientific thinking as a whole, in jumping precipitately from the contradictions of sense to an ideal unity or cause lying behind them This, Plato, in common with most Greek thinkers, was ready to find in an abstract construction of the mind The mind of the thinker, thus set to work by the impact of sense impressions, then proceeded to work untrammelled in its interior isolation, and produced a result eminently satisfactory to the inward eye but certain to be shattered so soon as later observation confronted it with obstinate fact This intently abstract and mental quality of Greek thinking accounts for their brilliant contributions to mathematics and their comparative failure to build up any efficient system of laws in the actual physical universe of which we are a part The analogy of certain modern mathematical thinkers whose work is noticed from time to time in these pages immediately comes to the mind F S MARVIN

Virus Diseases and the Bacteriophage

Medical Research Council A System of Bacteriology in relation to Medicine Vol 7 By C H Andrewes, J A Arkwright, S P Bedson, F R Blaxall, F M Burnet, J Burton Cleland, A Felix, G Marshall Findlay, W Fletcher, I A Galloway, M H Gordon, J G Greenfield, W E Gye, W F Harvey, E Hindle, P P Laidlaw, J C G Ledingham, R J Ludford, J E McCartney, J McIntosh, A G McKendrick, H B Maitland, M S Mayou, R St John-Brooks, J Henderson Smith, A Theiler, C Todd, J Walker Pp 509 (London H M Stationery Office, 1930) 21*s* net

THIS volume deals wholly with virus diseases and the bacteriophage A review of it is somewhat difficult because divergent opinions exist regarding these viruses and the diseases they produce, and much of the information is necessarily uncertain and based on somewhat feeble foundations At the same time, the interest in the subject is widespread, and it is well to have collected the main facts and theories into one volume

There is necessarily a considerable amount of irregularity in the merits of the various articles Some of these are written by men who have themselves an intimate knowledge of the subjects they deal with, while others are mere compilations from the work of others, and sometimes one asks why this special author has been chosen when others with practical experience of the diseases described could be found One always sympathises with an editor who has to find someone to do the work when the man who ought to do it has refused, and this may possibly be the explanation of the choice in some of the cases

The introductory survey in Chap. 1, by Gye and Ledingham, and the chapter on cell inclusions are well written and give all the essential facts for those

who propose studying these diseases, but they also discuss and criticise the theories that have been suggested, and this method of dealing with the subject is both interesting and helpful to the reader

The illustrations in Chap ii will be welcomed, though we think that clearness would have been gained if some colour had been used

Chap v, on foot-and mouth disease, gives an excellent account of the work on this subject up-to-date, though one misses any reference to the now proved spontaneous outbreak in rats, established quite clearly by the Ministry of Agriculture Though this article is well written, we think some parts of it might have been improved by the association with the author of someone with wider knowledge of the veterinary aspect of the disease The chapter on smallpox is excellent, and written in a truly critical way by a man evidently thoroughly familiar with his subject

Among the other outstanding chapters are those on encephalitis lethargica and acute poliomyelitis, by Prof McIntosh, dog distemper, by Dr Laidlaw, pleuro-pneumonia of bovines, by Walker, and typhus fever, by Arkwright and Felix Though we may not agree with all the statements in these chapters, yet the facts are extremely well put, and the case for the conclusions strongly supported by evidence largely obtained by personal practical work by the authors Virus disease work will no doubt produce many facts in the future which may bring about considerable changes in our present views, but the work in these chapters will largely remain as fundamental

Yellow fever is a disease which has led to much controversy, but in Chap xxxviii Hindle has put the present position clearly and has given a well-considered account of the disease and its virus The bacteriophage, even a more controversial subject, has been well and adequately treated by Dr Burnet

The virus diseases of plants and of insects have also been dealt with There is a short but interesting chapter on acute disseminated encephalomyelitis and its relation to vaccinia, measles, etc, by Dr Greenfield, which is well worth attention In view of much recent work, the chapters on herpes and varicella are of value Rabies is very fully dealt with by Harvey and McKendrick, and the chapter on measles is also worthy of careful study

Of the rest of the volume little need be said Those who are interested in such animal diseases as fowl plague, fowl pox, cattle plague, swine fever, etc, will find most of the information on the bacteriology of these diseases in various chapters, and practically all the diseases attributed to viruses are included Most of these chapters are interesting, though many of them are mere compilations from papers by various authors The advisability of having included some of them, considering the present uncertainty of our knowledge, is at least questionable, unless we are to have revised editions at frequent intervals Even since some of the articles have been written, new information has been gained which might modify some of the views propounded To take one example, we find no mention of the work on psittacosis

Considering our lack of knowledge of the nature of the viruses, and the mass of literature—much of it undigested and contradictory—which has, within recent years, found its way into the journals, we congratulate the authors, as a whole, on the completion of what must have been a somewhat difficult task They have produced a volume which will prove very helpful to all workers on the subject, and will prove to be not the least valuable of the volumes already issued J M BEATTIE

Early Beliefs

(1) *Ghosts and Spirits in the Ancient World* By Dr E J Dingwall (Psyche Miniatures General Series No 28) Pp 124 (London Kegan Paul and Co, Ltd, 1930) 2s 6d net

(2) *Possession, Demoniacal and other among Primitive Races, in Antiquity, the Middle Ages, and Modern Times* By Prof T K. Oesterreich Authorised translation by D Ibberson Pp xi+400 (London Kegan Paul and Co, Ltd, 1930) 21s net

(3) *Animism, Magic and the Divine King* By Dr Géza Róheim Pp xviii+390 (London Kegan Paul and Co, Ltd, 1930) 21s net

INTEREST in what the second-hand booksellers' catalogues call 'the occult' is perennial Here, if anywhere, is common meeting-ground for civilisations widely apart in time and space The mascot is the fetish reborn spiritualism and the cult of the dead are at one in their belief in the near presence of those who have 'passed over', and their concepts of the spirit-world might well be regarded as interchangeable

Both Dr Dingwall and Prof Oesterreich suggest this reflection, the one specifically, the other by implication The former points out that many early records of apparitions might have been written almost word for word to describe phenomena of

modern spiritualism. the latter places the data of possession among primitive races side by side with descriptions of the consciously induced states of the medium

(1) Dr Dingwall writes from the viewpoint of a scientific historian He gives an account of the means employed in ancient times—in Egypt, Mesopotamia, among the Hebrews, and in the classical world—in order to make effective the belief in the existence of spirits, good and bad Such, for example, are divination and other magical practices The use of the waxen image, familiar in modern witchcraft, goes back to ancient Egypt Dr Dingwall also recalls some of the well known cases of apparitions in Greek and Roman literature, as well as the remarkable spiritistic phenomena from ancient China Chinese records of clairvoyance and telepathy, telekinesis, poltergeists, spirit-writing, and so forth, afford a remarkable parallel with the performances of the modern medium The real problem is, however, how far these records may be regarded as constituting evidence which bears upon the quest of modern psychical research Is there behind these stories, asks Dr Dingwall, something which we are not yet in a position to explain?

Dr Dingwall's conclusion is cautious, but he does hold finally that the records throughout the ages show that there have been manifestations which, after making allowances for fraud and delusion, point to something which is still unexplained and offers a field for research on strictly defined scientific lines

(2) Prof Oesterreich's treatise is a translation of a work which first appeared in German so long ago as 1921 It may be mentioned here as the direct antithesis to Dr Dingwall's method of attacking the problem Prof Oesterreich's wide survey of the phenomena of possession among primitive races, in antiquity and in modern times, deals with the subject on psychological lines as the manifestation of an abnormality, whether automatic or induced A translation of this work is very welcome, especially as its free use of verbatim quotation makes it a mine of information for the student

(3) Dr Róheim's work is a re-examination of early forms of belief and ritual, especially those conceptions relating to magic and fertility with which "The Golden Bough" has made us familiar They are here translated into a whole-hearted sexual symbolism. In this extreme form the argument will scarcely convince anyone but an already fervent disciple of Freudian psychology.

Our Bookshelf

Handbook of Chemical Microscopy By Prof Émile Monnin Chamot and Prof Clyde Walter Mason. Vol 1 *Principles and Use of Microscopes and Accessories, Physical Methods for the Study of Chemical Problems* Pp xiii+474 (New York John Wiley and Sons, Inc, London Chapman and Hall, Ltd, 1930) 22*s* 6*d* net

Although the microscope has now become firmly established in the chemical laboratory, the average chemist is none too familiar with the instrument, and its possibilities are likely to be under-estimated This volume offers to research worker, analyst, or technical chemist a useful compendium of microscopic technique, together with a clear explanation of the theory of the microscope, an understanding of which is essential for trustworthy and accurate work, especially at the higher magnifications The various methods of illumination are set out, and their effects on resolution and contrast well explained

Short sections devoted to ultra-microscopy, photomicrography, and the quantitative analysis of mixtures by microscopic methods dependent on counting or measurement will offer little fresh to the specialist, but should greatly assist the worker in another field, especially as there are adequate literature references

One of the most valuable uses of the microscope to the chemist is in the determination of the optical properties of crystalline material for determinative or research purposes, and here the treatment appears somewhat cramped The average chemist knows little of optics and less of crystallography, and so short a summary of crystal optics is likely to deter rather than to encourage him to refer to one of the text books on this subject The bibliography, too, is inadequate in this direction—a most disappointing perpetuation of the neglect of this field Much space is devoted to the description of microscopes and accessories, this is a useful feature, but, unfortunately, dealt with almost exclusively from an American point of view M H H

The Economics of Forestry By W E Hiley (Oxford Manuals of Forestry) Pp xiv+256 (Oxford Clarendon Press, London Oxford University Press, 1930) 21*s* net

This book, the author states, is founded upon courses of lectures given in the Oxford School of Forestry and the Imperial Forestry Institute The treatment of the subject differs from that followed by Schlich in his well known "Forestry Manual", which has been used by generations of British-trained foresters It is not at first sight easy to follow the author in his methods The first part of the book is devoted to timber supplies, consumption, and prices, compiled from trade statistics in several parts of the world, and from other authors In Part II Hiley treats of finance and its importance But it differs from Schlich's well-known "Valuation and Management" (vol 3) in that Hiley has jettisoned most of the accepted formulæ of 'forest valuation' The author admits that

some of the formulæ omitted may in the future prove useful If this is the case, the student should be made acquainted with them

Formulæ are not the only omissions The author writes "I have said nothing about the selection system of forest management, because I have been unable to find any reliable data on which to estimate profitableness under this system" A very large proportion of the forests of the British Empire are managed on some form of selection system, and must continue to be so managed for a long time to come Further, Hiley states that the financial aspects of forestry have not received in the past sufficient notice, "since the care for forestry has been based on the objective of general human welfare rather than financial gain, and emphasis has been placed on the indirect benefits which forest maintenance often confers" In many of the forests of the British Isles the indirect benefits outweigh the direct financial ones, and a text-book should place the two aspects before the student There are many good things in this book, but the omissions appear serious

Electrical Power Transmission and Interconnexion By C Dannatt and J W Dalgleish (The Specialists' Series) Pp xi + 424 (London Sir Isaac Pitman and Sons, Ltd, 1930) 30s net

The transmission of electrical energy has now become a very important engineering problem It is not surprising, therefore, that the literature on the subject is increasing very rapidly The expert finds a difficulty in keeping abreast of the advancing tide of knowledge Consequently, there is room for a book which describes the latest developments in the theory of transmission This book is written by two capable engineers, and it is interesting to notice how they have collected, from the advanced treatises and papers they have studied, the theorems which have great practical value whether they are easy to understand or not On p 11, for example, we come across Maxwell's coefficients of capacity and potential The schoolmaster in us objects, however, to such statements as "It will be obvious that $p_{12} = p_{21}$" This kind of assertion we come across in examination papers In these cases we take it to mean that the examinee does not see it himself but hopes that it is obvious to the examiner

What pleases us most about the book is that it is thoroughly up-to-date, and that only really important practical theorems are given There are some defects in methods of proof, but in no case, so far as we have noticed, is the defect serious We confess to feeling annoyed every time we come across Kirchhoff's name spelt with only one *h* One of the most valuable chapters in the book is on the relative value of earthing as compared with insulating overhead high tension networks In Great Britain we generally use solidly earthed neutrals In Germany they are earthed through Petersen coils, so called after their inventor, Prof Petersen, of Darmstadt At the present time, there is scarcely sufficient operating experience available to determine which system is the best, but the authors state the problem clearly

Dictionary of Biological Equivalents German-English By Ernst Artschwager. Pp 239 (6 plates) (London Baillière, Tindall and Cox, 1930) 20s net

In 1921, Dr Ernst Artschwager and Edwina M Smiley published a small "Dictionary of Botanical Equivalents", which was concerned with accurate translations of French-English, German-English terms employed in botanical science Now Dr Artschwager has prepared another dictionary of German-English equivalents embracing the wide field of terms employed in biological science Owing to the extreme specialisation in biology which, as the author points out in his preface, "has increasingly narrowed the working sphere of the individual", the need for accurate, easily found translations of the technical terms employed is obvious, since every worker must needs keep abreast with related aspects of his own branch of natural science

The book contains lists of abbreviations used, the common German abbreviations, irregular verbs, metrical equivalents, references used in compilation, as well as the dictionary itself At the end of the book are six plates dealing with the morphology of plants and animals, which enable the reader to see at a glance the required equivalent, since the drawings are numbered and the key faces the illustrations Dr Artschwager is to be congratulated on producing a book so comprehensive in scope, and the publishers on the clear printing The book is strongly recommended to those who have little knowledge of German technical terms which are employed in the various aspects of biological science

The Structure and Meaning of Psycho-analysis as related to Personality and Behavior By Dr William Healy, Dr Augusta F Bronner, and Anna Mae Bowers Pp xx + 482 + xxiv (London and New York Alfred A Knopf, Ltd, 1930) 21s

It is difficult to imagine the audience for which this book is intended It purports to be the outcome of an attempt to show "psycho analysis as one of the scientific approaches to understanding of personality in a projected manual of methods of personality study", and the maze of material prompted the authors to compile "an organised statement of what had been contributed to date in psycho analysis" On the left-hand page are given what are considered to be the orthodox theories as presented by Freud, while on the right-hand page are the various modifications suggested by other writers The result, while being an admirable testimonial to the patience of the compilers, can scarcely be called useful For serious students the best approach is the original work of first-hand exponents, while for those who want to get a general idea of such work there are innumerable popular manuals, if it is to be considered as a reference book, then far more bibliographical references are needed Neither the structure nor the meaning of any subject can be adequately presented in this way

Stellar Structure

IT has frequently been stated, by myself amongst others, that it is necessary to assume in the inside of stars a temperature of the order of mc^2/k in order to explain the generation of energy by the annihilation of matter, m being the mass destroyed in each process, c the velocity of light, and k Boltzmann's constant. This letter is written in order to make clear that this assumption is not necessary. It is perfectly true that the equilibrium constant of a process, subject to the laws of thermodynamics, is of the order $e^{-\epsilon/kT}$, ϵ the energy of the process in this case, of course, being equal to mc^2. The equilibrium constant does not, however, determine the generation of energy. What one is concerned with in the case of a star is the rate at which energy is produced; in other words, if one presupposes the simplest process of annihilation, the rate at which protons and electrons disappear in the form of radiation. This is analogous to the rate of chemical reaction, not to the equilibrium constant of a reversible reaction.

In most chemical processes the rate of reaction is governed by the number of molecules activated per second, which again depends upon the number of particles the energy of which exceeds a certain value, say, ϵ_1. This number is proportional to $e^{-\epsilon_1/kT}$, and one therefore finds, roughly speaking, that the rates of reaction are negligible unless the temperature is such that the mean energy of the molecule is comparable with the energy of excitation. Since this activation energy is usually of the same order as the energy of the reaction, the conclusion is often extended without great inaccuracy to the total energy of the process.

In the case under consideration, the annihilation of protons and electrons, it seems difficult to imagine any form of excitation, and the rate at which it proceeds can therefore scarcely depend upon a function of this type. Presumably, in such collisions as are effective, certain circumstances, which occur but rarely, have to be fulfilled. When these are fulfilled, and they may not be such as require any high velocities, matter is converted into radiation; in the vast majority of cases, a collision has no such result. If this view is correct, the rate of annihilation, and therefore the rate of generation of energy, will depend in the first instance on the number of collisions per second, which of course varies with the density and with something like the square root of the temperature, and in the second instance, upon the special circumstances which render a collision effective, and which may, or may not, depend upon the temperature. In either event the simple exponential expression is not applicable, and the conclusion that matter can only be annihilated and energy produced in stars where interiors are at temperatures of the order mc^2/k, that is, 1.1×10^{13} degrees, is valid.

It would be true if the matter radiation equilibrium has been attained and any further production required a change in the equilibrium constant. It is incorrect if the system has not reached equilibrium, for in this case thermodynamical reasoning is insufficient to determine the rate at which equilibrium will be approached.

Oxford, Feb. 5.

REFERRING to Sir James Jeans's letter in NATURE of Jan. 17, p. 89, I may say that I fully acknowledged in my paper of November 1929 (*Mon. Not. Roy. Ast. Soc.*, **90**, p. 20) that Sir James was the first to recognise the principle that the mass M and luminosity L of a star are independent variables as regards steady state considerations. On p. 53 of that same paper (a page of which Jeans himself quotes in another connexion) I made a general reference of obligation to his work. In my last paper (*Mon. Not. Roy. Ast. Soc.*, **91**) I build on Jeans's permanent contributions to science in three places, mentioning him by name (pp. 4, 9, 51). I could not, however, adduce any of the specific results of his theory of stellar equilibrium in support of my conclusions, for they are totally different; and I could not contrast his results with mine without venturing to discuss his mathematics.

I cannot assent to Jeans's mathematics, because his theory of stellar equilibrium is in formal contradiction with his own (L, M) independence principle. It is an immediate consequence of this principle that for a given mass M in equilibrium the ratio λ of gas pressure to radiation pressure may have any value whatever between zero and infinity, depending on the arbitrarily assigned L. This is fundamental in my analysis. According to Jeans ("Astronomy and Cosmogony", pp. 88, 89) λ is small for large masses and large for small masses, and is calculable in terms of M (p. 97). Jeans may claim the principle, but his theory is not consistent with it.

The point of my analysis is the construction of configurations which satisfy the (L, M) independence principle, even for models for which $\kappa\eta$ is constant. The special properties attributed to these models by both Jeans and Eddington then disappear, and the new general properties which emerge (explaining as they do why some stars are very dense and others not) are shared by other models, since they depend only upon the occurrence of the central singularity $r=0$ in a certain system of differential equations. Jeans uses throughout Emden's solutions, which possess no singularities.

As regards the branching out of solutions near the boundary of a star, Jeans is considering a variety of models. *For any one model*, the solution is unique up to the boundary. The work of Mr. Fowler, Mr. Fairclough, and myself published in *Mon. Not. Roy. Ast. Soc.*, **91** (November 1930), discusses the family of such solutions arising from Emden's equation; with any definite configuration, of arbitrarily assigned mass, luminosity, and opacity, there is associated *one* member of the family of solutions, selected by a boundary condition which ensures that the boundary layers, of the prescribed opacity, enclose M and radiate L.

Generalisations and Modern Cosmogonies

PROF. R. A. MILLIKAN in his retiring presidential address of the American Association for the Advancement of Science (NATURE, Jan. 31, p. 167), refers to the assumption "that the radiation laws which seem to us to hold here cannot possibly have any exception anywhere" as "precisely the sort of sweeping generalisation that has led us physicists into error half a dozen times during the past century." This emboldens me to ask again whether there is any evidence whatever for the uniform propagation of radiation in all directions in space from a sun or a star. I asked it (NATURE, Nov. 29, 1913, p. 339) at the time of Millikan's "fifth significant discovery", when radioactivity was indicating the necessity of extending

the cosmical time scale Since then all modern cosmogonists it seems to me have constructed systems designed primarily to account for the maintenance of solar and cosmical energy on the scale demanded by this natural but perhaps unwarranted assumption

Although I have no desire to trespass in the controversies concerning the nature of cosmical radiation I may say that Millikan s views have always had a singular attraction to me because of the very difficulties to which he refers of finding a satisfactory kinetic picture of the instantaneous conversion of say 56 separate hydrogen atoms into one iron atom This to a chemist a reaction of the 56th order seems bizarre for has not Sir Joseph Larmor educated us to regard a reaction even of the third order as difficult to form any kinetic picture of ? But I like to think of these 56 atoms (or shall we say 55 ?) holding a committee meeting in the spacious regions of zero temperature and concentration with infinite time ahead of them and nothing to disturb them arriving at a decision (or possibly only awaiting a chairman) to rush into one another s arms and flash to us the birth of an iron atom

Change of Density of Ethyl Ether with Temperature

IN connexion with my former studies on ethyl ether made in the Physical Laboratory of the Technical Institute at Warsaw I have made a study of the dependence of the density of ethyl ether upon temperature in the interval between 120° C and + 35° C using the method described by H Kamerlingh Onnes and J D A Boks (*Comm Leyden* No 170 b)

The dilatometer and the control tube were made of fused quartz carefully calibrated and provided each with a closely fitting quartz stopper The dilatometer was placed in a deep glass Dewar vessel so as to permit the observation of the level of liquid in the dilatometer The temperature was determined by two platinum resistance thermometers placed at different depths

There was great difficulty in selecting the cooling liquid The specially purified petrol ether which is commonly used for this purpose permits of lowering the temperature to 150° C but even at 70° C it

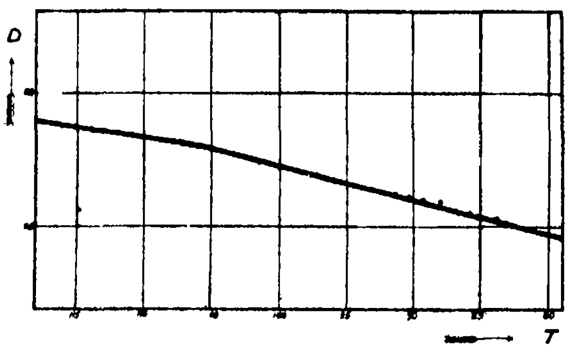

FIG 1

becomes so markedly disturbed as to make the observation of the levels of the liquid both in the dilatometer and the control tube quite impossible After several attempts I found that a mixture of chemically pure ethyl ether and ethyl alcohol remains clear down to 120° C Probably this is due to the fact that ethyl alcohol absorbs the last traces of moisture in the cooling liquid which would otherwise cause it to become disturbed at low temperatures

The density of ethyl ether as a function of temperature in the neighbourhood of the point 105 4° C is represented on the accompanying graph (Fig 1) The shape of the curve shows that the density of very carefully purified ethyl ether increases with the lowering of temperature from the value 0 6964 at 35° up to 0 8595 at 105 4° C With further lowering of temperature the density of ethyl ether still increases but the rate of increase is markedly lower According to former studies made in this laboratory there appears also at this temperature a change of the value of the dielectric constant and of the specific heat of ethyl ether (J Mazur NATURE 126 649 1930 M Wolfke and J Mazur NATURE 126 684 1930) Thus at the previously found transition point 105 4° C the density curve shows also a distinct change of character At 117 2° C (freezing point) the density has the value 0 8654

Crystal Structure of Martensite

IT was first shown by W L Fink and E D Campbell (*Trans Am Soc Steel Treat* **9**, 717 1926) and independently by N Seljakow J Kurdumoff and N Goodtzow (NATURE **119** 494 1927) that quenched carbon steels contain a phase with a tetragonal crystal structure which might be considered as a deformation of the body centred cubic structure of α iron This has been confirmed by other investigators and our present knowledge of the tetragonal martensite may be briefly summarised as follows The axial ratio increases from about 1 03 at 0 8

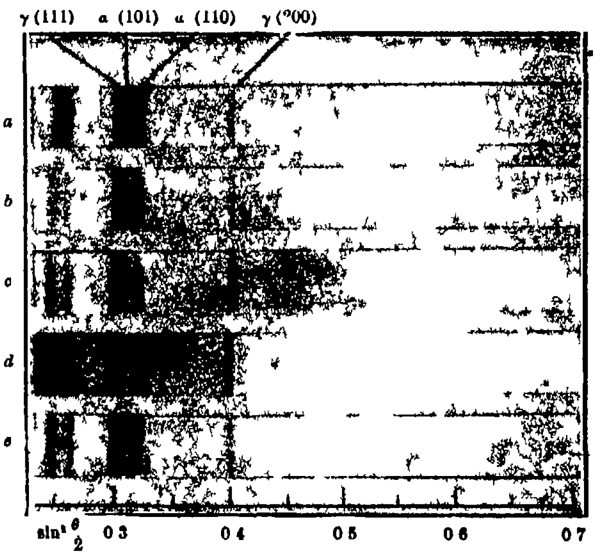

FIG 1 X ray photograms of quenched carbon steels The two lines γ ( ) and α (0) are separated in the original films a 0 80 per cent carbon b 1 04 per cent carbon c 20 per cent carbon d 1 35 per cent carbon e 1 35 per cent carbon after forty eight hours in liquid air

per cent carbon to 1 06 at 1 4 per cent carbon At lower contents of carbon the interference doublets corresponding to the tetragonal lattice are not resolved but in photograms of very rapidly cooled specimens the α Fe lines are slightly displaced in such a way as to indicate a tetragonal deformation The higher the carbon content and the higher the axial ratio the larger is also the volume of the unit cell

It is thus evident that there is a correlation between carbon content and lattice dimensions and it must be considered as an established fact that the tetragonal martensite has a homogeneity range of considerable

extent. Recent investigations by means of thermal (Ed. Maurer and G Riedrich, *Archiv f d. Eisenhütten wesen*, **4**, 95, 1930) and microscopic (F Wever and N Engel, *Mitt a d Kaiser-Wilhelm Inst f Eisenforschung*, **12**, 93, 1930) analysis have shown that the austenite martensite change takes place also in steels with a very low content of carbon This is in favour of the assumption that the tetragonal martensite is a supersaturated solution of carbon in α iron An X-ray investigation by G Kurdumoff and E Kaminsky (NATURE, **122**, 475, 1928) points very strongly in the same direction They find the dimensions of the axes c and a of the tetragonal phase to be linear functions of the carbon content, and the lines to intersect at a point corresponding to the elementary cube edge of pure α-iron On the other hand, Wever and Engel refrain from stating the axial dimensions obtained in their X-ray work, and emphasise the difficulties of exact determination, due to the diffuse interference lines and to the fact that the strongest lines of the tetragonal phase are covered by either γ- or α-iron lines

By using focusing cameras constructed by G Phragmén, which give a much higher dispersion than the ordinary Debye cameras, and by employing chromium *K*-radiation, which has a comparatively long wave-length, I was able to obtain photograms of quenched steel specimens of which the line (101) of the tetragonal phase is separated from the γ-Fe line (111) It was thus possible to determine the lattice dimensions of the tetragonal structure from the strong and comparatively sharp lines (101) and (110) Some of the photograms are reproduced in Fig 1 The results obtained are given in the following table

Per cent Carbon	Tetragonal Phase				γ Iron	
	a	c	c a	Volume per lattice point	a	Volume per lattice point
0 71	2 853 A	2 941 A	1 031	11 97 A³	3 581 A	11 48 A³
0 80	2 852	2 956	1 036	12 06	3 584	11 51
1 04	2 848	2 979	1 046	12 08	3 592	11 59
1 20	2 846	2 999	1 054	12 15	3 600	11 66
1 35	2 843	3 014	1 060	12 18	3 609	11 76
1 40	2 840	3 034	1 068	12 23	3 616	11 82

The results are reproduced graphically in Figs 2 and 3 The correlation of the points belonging to the tetragonal phase is very satisfactory The two curves of Fig 2, giving the axial dimensions as function of the carbon content, converge to a point corresponding to the edge of the elementary cube of pure α-iron, in complete agreement with the result of Kurdumoff and Kaminsky The present investigation has thus completely confirmed the assumption that the tetragonal martensite is a supersaturated solution of carbon in α-iron Ferrite and tetragonal martensite are thus one and the same phase, but as they are often present in one and the same specimen as separate micrographic structure elements, it seems convenient to denote the tetragonal phase as α′

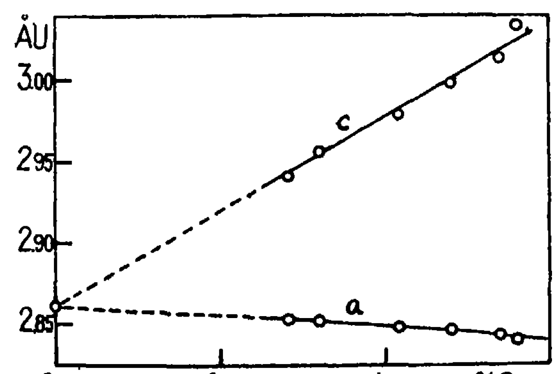

FIG 2.—Lattice dimensions of the α phase as function of the carbon content.

As shown by A Westgren and G Phragmén (*Jour Iron and Steel Inst*, **109**, 159, 1924), the carbon atoms, when dissolved in γ iron, do not occupy any points of the face centred lattice, but are statistically distributed in the interstices between the iron atoms Seljakow, Kurdumoff, and Goodtzow (*Zeit f Physik*, **45**, 384, 1927) suggested that the same might be the case in the α′ phase, and even proposed definite positions for the carbon atoms which would explain the tetragonal deformation, namely, at the centre of those faces which are perpendicular to the tetragonal axis This atomic arrangement is, however, very improbable, as the space available for the carbon atoms would be extremely small But even if a carbon atom were situated in one of those points, where the distances to the surrounding iron atoms are the greatest (½ 0 ½), the space available for the carbon atoms would be considerably smaller than in the face centred structure One would therefore expect the volume of the body centred lattice to increase much more rapidly with the carbon content than that of the face centred, while, as seen from Fig 3, the opposite is in fact the case On the other hand, a simple substitution of carbon atoms for iron atoms in the lattice would cause a decrease in the lattice dimensions, as the carbon atoms are much smaller than the iron atoms

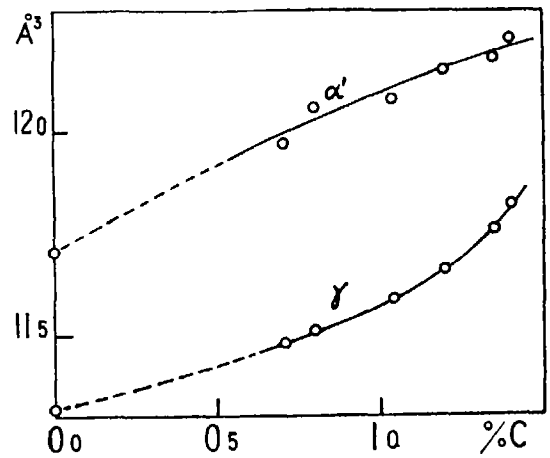

FIG 3 —Volume per lattice point for the α and the γ-phases as function of the carbon content

I am indebted to Dr G Hägg for the suggestion of still another possibility, namely, a complex substitution in such a way that a group of two carbon atoms is substituted for one iron atom in the lattice Such groups of carbon atoms have, in fact, been found by M v Stackelberg (*Zeit phys Ch* (B), **9**, 437, 1930) in several carbides of the composition MC_2 and a similar arrangement of hydrogen atoms by Hägg (*Zeit phys Ch*, in press) in ZrH_2 These compounds all have a tetragonal structure, and in most cases the axial ratio is higher than one, which is contrary to what is generally the case in deformed cubic structures This is explained by the assumption that the C_2 group is in these cases orientated parallel to the tetragonal axis, an explanation which holds equally well for the tetragonal martensite.

An attempt was made to find the positions of the carbon atoms by means of density determinations The density of the a' phase when containing 1 35 per cent carbon was calculated on the following three assumptions

(1) Addition of carbon atoms	7 65
(2) Complex substitution of carbon atoms	7 42
(3) Simple substitution of carbon atoms	7 19

A steel specimen with this content of carbon was quenched and afterwards placed in liquid air for 48 hours in order to increase the percentage of the a'-phase The density was found to be 7 62 As shown by an X ray photogram (Fig 1, *e*), the specimen consisted of a'- and γ iron, and the intensities indicate that there was more tetragonal martensite present than austenite The density of austenite with this composition is found by calculation to be 7 94 Assumption (1) is immediately ruled out, as the densities of both components would be higher than that of the mixture Assumption (3) has been shown above to be very improbable and would give 57 per cent γ iron, 43 per cent a' iron, while the X ray intensities indicate that the a' phase predominates Assumption (2) gives 60 per cent a' iron, 40 per cent γ-iron, in good agreement with the X-ray intensities

The only suggested structure of tetragonal martensite which explains the observed density, the increase of volume with the carbon content, and the elongation of one of the crystallographic axes may be described as follows In the body centred lattice, groups of two carbon atoms, statistically distributed, replace some of the iron atoms The carbon atoms are most probably orientated in such a way that the axes of the C_2 groups are parallel to the tetragonal axis of the lattice

The decomposition of the a' phase on tempering, as well as the reactions occurring on ineffective quenching, have also been studied, and the results obtained will be published elsewhere, with a more detailed account of the results reported here

A Laboratory Method of demonstrating the Formation of Fronts and Vortices when there is discontinuous Movement in a Fluid

ACCORDING to views now generally accepted, extratropical cyclones are formed along surfaces of kinematical discontinuity between air-masses having different temperatures and moisture-contents, and during their growth they possess an asymmetrical structure Recent studies [1] of tropical cyclones show that they also have often a similar origin and structure

It is well known that vortices can easily be formed in a fluid by producing a sufficiently sharp discontinuity of velocity—as by suddenly moving a half immersed spoon across the surface of water A common method of studying stream-lines in water is by strewing aluminium powder on its surface. With water, however, the movement is so rapid that it is often difficult to follow its details Melted spermaceti, in which aluminium powder is suspended, is a very convenient medium for the demonstration and study of fronts and vortices similar to those which occur on a much larger scale in Nature

If a shallow layer of spermaceti is heated in a flat enamel dish over a plate of copper or brass, then, as is well known, the liquid layer is divided up into a series of small polygonal cells with liquid rising at the centres of the cells and falling at their peripheries If, now, a cylindrical rod is moved across the liquid with its axis vertical, the formation of the Kármán double row of vortices can be distinctly seen By

(a) (b) (c) (d)

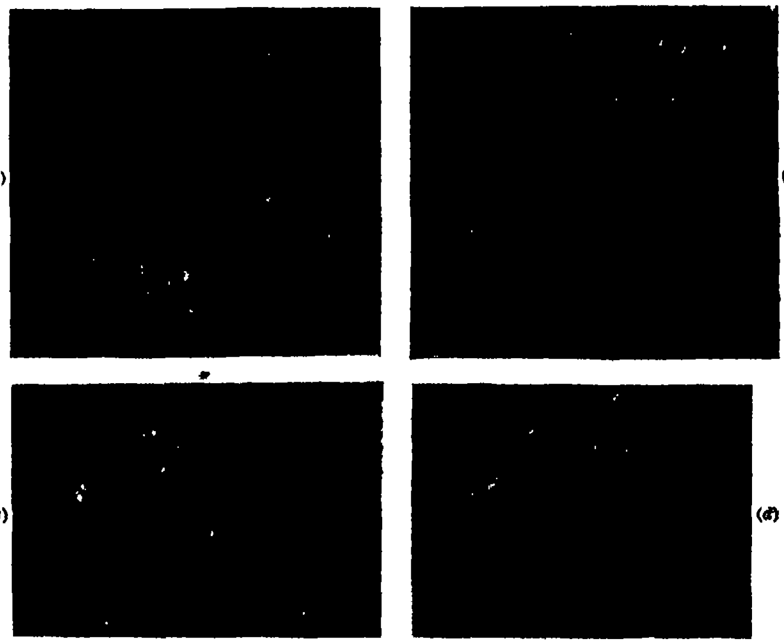

FIG 1

substituting a thin small angled wedge of wood with its narrow end dipping in the liquid, and moving it across the surface with its axis inclined, a wave motion is set up, and the stream which flows past the thicker end of the wedge rolls up into a succession of vortices which persist for some time before they disappear The development of these vortices resembles in many ways the development of a cyclone by the incursion of a tongue of warm air in cold air Fig 1 (*a*) and (*b*) shows photographs of such waves and vortices, the area of disturbance being obviously larger in the latter case When the liquid is at a low temperature, or when the speed of movement of the wedge is small, waves are set up without the formation of vortices, similar to those studied in the atmosphere by Bergeron and Swoboda (Fig 1 (*c*)) By giving a circular movement to the wedge, the series of cyclones along the polar front can be neatly imitated (Fig 1 (*d*))

The interesting question as to how far the instability of the liquid layer helps the formation and persistence of these vortices is being examined

[1] K R Ramanathan and A A Narayan Iyer "The Structure and Movement of a Storm in the Bay of Bengal during January 1929"

Modification of Quanta by Photo-Ionisation

IN the course of further experiments on the phenomenon described by Dr B B Ray (NATURE, May 17, p 746, and June 7, 1930, p 856), which was explained by Dr Ray and one of us (NATURE, Sept 13, 1930, p 398) as a case of partial absorption of the quantum leading to photo ionisation, we came across an interesting experimental result On using the copper $K\alpha_1, \alpha_2$ radiation and passing it through paraffin 1 mm thick, we obtained a modified line on the long wave length side, separated from the parent line by the approximate frequency distance $\Delta\nu = R$ (R = Rydberg constant) We are inclined to interpret it as a case of photo ionisation of hydrogen contained in paraffin in the combined state

In these experiments, a Uhler and Cooksey type of X ray spectrometer supplied by Messrs A Hilger, Ltd , was used The crystal of calcite was kept fixed The photographic plate was firmly clamped in the plate holder, which is itself a heavy metallic one and is firmly clamped to the body of the spectrograph, leaving no chance of the plate being displaced during an exposure The modified line was obtained on three plates only when a layer of paraffin was used as an absorber

The other alternative was to ascribe this line to partial absorption of the quantum by an electron in the aluminium (used as window) L_1 shell, but this explanation fails, as the energy of ionisation of aluminium in the L_1 shell is found to be equivalent to about 5 3 R, that is, about 72 volts, according to a recent paper by Söderman (*Phil Mag*, 616, Sept 1930)

In a previous letter (NATURE, Sept 13, 1930), it was pointed out that the phenomenon is analogous to the ejection of electrons from the K-shell of radioactive atoms by γ ray quanta coming from the nucleus, as found by L Meitner, Ellis, and others But there is one important difference The γ ray is supposed to impart the whole of its energy to the K-electron, which is therefore ejected with the energy $h(\nu - \nu_k)$ But in the present case, the X ray quantum is supposed to impart only a fraction $h\nu_k$ ($h\nu_k$ stands for energy of ionisation in the K shell) and then continues its journey with the energy $h(\nu - \nu_k)$ The two cases are therefore two extremes of the same phenomenon

It therefore seems probable that the quantum, whether internal (coming from the nucleus) or external (coming from an outside source as an X ray quantum), may on its passage through atomic shells impart any part of its energy to the electron from $h\nu_k$ to $h\nu$, and be therefore modified from ν to the frequency range $\nu - \nu_k$ to 0 We should expect that the modified beam will appear as a band with a sharp edge at $\nu - \nu_k$ and extending towards the longer wave length side indefinitely

We undertook to verify this deduction by sending the radiation through four layers of black paper (that in which photographic plates are wrapped), we have actually found evidence of this continuous band with a sharp edge at $\nu - \nu_k$ and extending towards the long wave length side indefinitely The copper $K\beta_1$ line was used in this case, and the crystal was kept fixed The range covered by the divergent beam of X rays was about 45′ (equivalent to 70 X U) The crystal was so placed that it could reflect all the wave-lengths between copper-$K\beta_1$ and copper $K\beta_1$ + 70 X U A single exposure of 50 hours' duration was given A feeble continuous radiation was indeed recorded in this region, and superposed on this was the modified line with a sharp edge on the short wave-length side and extending towards the long wave-length side as stated in the previous paragraph The separation between the edge of this line and the parent line was about 20 in ν/R units—20 4 being the C level in ν/R units as found by Söderman (*Zeit f Phy*, 52, 1929) A separate exposure was given for 10 minutes to record the copper $K\alpha_1, \alpha_2$ lines for reference and measurement No continuous radiation was recorded in the neighbourhood of copper $K\alpha_1, \alpha_2$, as the former is too feeble to be photographed in an exposure of 10 minutes

These experiments seem therefore to prove that the phenomenon is general, and the quantum can impart to the bound electron energy varying from $h\nu$ to $h\nu_k$, and be modified to any frequency less than $\nu - \nu_k$ Further experiments are proceeding

Simple Deposition of Reactive Metals on Noble Metals

ACCORDING to Nernst's theory of electrode potentials, a very small concentration of a reactive metal should be deposited on a noble metal when the ions of the former are brought in contact with the latter The effect is usually regarded as being too small for demonstration Dr G von Hevesy showed the effect by radioactive methods some years ago He deposited radioactive isotopes of lead and bismuth, presumably as metal, on such noble metals as platinum, gold, mercury, and copper, in some cases quantitatively, he showed, indeed, that the ions of any radio element could to some extent be deposited on noble metals when the latter were merely immersed in a solution The effect, I find, can be shown by some metals which are not radioactive I have obtained it with reactive metals like uranium, titanium, tungsten, and molybdenum on such noble metals as mercury, copper, and tin

It is obtained simply A liquid amalgam is shaken vigorously with a solution of a uranium, titanium, tungsten, or molybdenum compound in acid for a few minutes or less, removed from the solution, and well washed To the amalgam 0 1 gram of pure zinc is added, and the minimum concentration of sulphuric acid at which hydrogen is found to be evolved determined Whereas with an amalgam employed as a blank no hydrogen is visible with $2N$ sulphuric acid, the amalgams which have been shaken with uranium, titanium, tungsten, and molybdenum solutions are found to evolve hydrogen down to concentrations of 0 012, 0 0025, 0 002, and 0 002 N sulphuric acid respectively This catalytic effect cannot be due to the mere act of shaking, since it is not given when acidified solutions of manganese, chromium, and vanadium, which are metals similar to those given above, are shaken with amalgams to which zinc is afterwards added Nor can it be ascribed to oxides or other compounds of these metals, since these have never been shown to catalyse the formation of hydrogen when zinc is brought in contact with a dilute acid In the well known experiment of adding copper sulphate or platinic sulphate to zinc immersed in acid in order to catalyse the evolution of hydrogen, it is difficult to think that the catalyst is not metallic copper or platinum These catalysts, uranium, titanium, tungsten, and molybdenum, behave as though they were deposited platinum, and are therefore presumably in the metallic state

This view is supported by the fact that any of these metals when deposited by a current on a mercury cathode behaves catalytically towards the evolution of hydrogen exactly as does the amalgam which has been shaken with a solution Such amalgams appear entirely metallic Uranium and titanium have

hitherto not been deposited electrolytically from aqueous solutions on a cathode, but this has been effected by Mr R Groves in this laboratory

Mercury is the noblest metal on which we have succeeded in depositing these four metals by mere shaking Amalgams of copper, bismuth, lead, tin cadmium, and zinc show the effect in increasing amount, but only with molybdenum have we shown the presence of the catalytic metal by chemical means The amount deposited must in all cases be very small The electrode potentials of the four metals I have mentioned have never been accurately determined, but published work places uranium with manganese, titanium with zinc, and tungsten and molybdenum with cobalt and nickel in the list of electrode potentials of metals These similarities are supported by the behaviour of the metals towards acids, the difficulty of reduction of their ions in aqueous solution to the metallic state, and such evidence It is quite certain, in any case, that all four are more electro positive than tin, and therefore than lead, copper, and mercury

It is fortunate that each of the catalytic metals, as appears from measurements we are making, is quite insoluble in mercury The very small concentration deposited on the amalgam by shaking thus forms a separate phase with practically no loss through solution in the mercury It is this separate phase which is the catalyst for the hydrogen evolution which enables the small concentration to be detected

Oxford, Jan 26

Development of Golgi Apparatus in Water- and Soil-grown Roots of *Vicia faba* Seedlings

WHILE *Vicia faba* is generally quoted as the type seed for successful germination in water under laboratory conditions, it is, nevertheless, noted that germination in sand is more rapid and much more reliable

The rate of growth of a seedling root under normal conditions depends on the activity of the meristem, and of the region of elongation This is directly related to the supply of available food material, which in turn is a function of metabolic rate, and consequently of respiration The respiration of a non hydrophyte, such as *Vicia faba*, might conceivably be adversely affected by growth in water Two series of seedlings were therefore grown, one in water and one in sand, to determine whether the difference in growth rate was linked up with any constant cytological variation

As has been already observed,[1] part of the food material visible in the cells of *Vicia faba* consists of Golgi apparatus, either in a reticular or granular form The examination of fifty seedlings, varying in length from one to sixteen centimetres, showed that such a Golgi apparatus is commonly present in dermatogen and periblem in both water- and soil grown roots It may be temporarily absent in the primary root during the early stage of development of the secondaries In the latter, as in the tertiary rootlets, it is also observed to occur The fixation method used is described in detail in the paper referred to above The sections were cut four to six microns thick

Swelling Pressure of Rubber

MEASUREMENTS of the swelling pressure of rubber (Stamberger and Blow, *Koll Zeitschr*, 53, 90, 1930) lead to the conclusion that the swelling pressure results from the attraction of solvent molecules by the molecules of gel A simple formula expressing the variation of molecular force of attraction with dilution, $P = K/V^2$, has been applied and gives satisfactory results In the present case P is the swelling pressure (MLT^{-2}), V is the volume of solvent bound to unit weight of jelly (L^3), K is a constant the meaning of which is obtained by substituting $P = K/V^2$ in the maximum work term $dA = PdV$

K is characteristic for all solvents and jellies, and expresses the potential energy when unit volume of solvent is bound to unit weight of the gel (The dimension of K is ML^5T^{-2})

The formula has been tested with all the data available and the constancy of PV^2 is fulfilled in a satisfactory manner

Full details will be published shortly

The Black-necked Grebe

I OWE thanks to the Writer of the Note on the black necked grebe for correcting my error in naming Linnæus instead of Latham as responsible for the generic title of the grebes (NATURE, Feb 7, p 201), but when he goes on to say that the "name is a label and need have no meaning in itself", I must ask how a label can be justified that conveys a false meaning, as *Podiceps* does Are misprints in scientific nomenclature to be reckoned indelible? That has not been the opinion of such ornithologists as Seebohm, A H Evans in the "Cambridge Natural History", and Prof Alfred Newton, who all write *Podicipes* In his "Dictionary of Birds", Newton notes about *Podicipedidæ*—"often, but erroneously, written *Podicipidæ* The word *Podiceps*, as commonly spelt, being a contracted form of the original *Podicipes* (*cf* Gloger, *Journal für Ornithologie*, 1854, p 430, note), a combination of *podex*, *podicis*, and *pes*, *pedis* its further compounds must be in accordance with its derivation"

Embryology and Evolution

IN NATURE of Jan 10, Prof MacBride appears to deny that a cross between two types of *Cavia* to which I referred, and which leads to Mendelian segregation, was an interspecific cross Not only did Detlefsen,[1] who carried it out, regard it as such, but, also, the male hybrids were wholly sterile In view of the latter fact, I did not suppose that Prof MacBride would question its interspecific nature

In spite of Prof MacBride's disbelief in auto catalysis, I hope to demonstrate this phenomenon to students of the Natural Sciences Tripos next week, as I have done annually for some years

New Aspects of Radioactivity *

By Dr C D ELLIS, F R S

γ-RAYS AND NUCLEAR STRUCTURE

UNTIL a few years ago, the fundamental problems of physics were those concerned with the structure of the atom The nucleus was necessarily often referred to, but only in relation to its effect on the behaviour of the electrons in the atom It was found that for most purposes the net charge, Ze, was a sufficient description of the nucleus Within, however, the last three years, the whole attitude of physicists to this problem has changed , on one hand, our knowledge of those phenomena which depend on the intimate structure of the nucleus has been greatly increased , on the other hand, wave mechanics has proved to be eminently suitable for a theoretical attack on this problem, and has already provided a solution of some of the outstanding problems

Of the many lines of investigation which have been developed, not the least interesting is that of the characteristic electromagnetic radiation that can be emitted by radioactive nuclei These radiations are termed the γ-rays and are in general of considerably shorter wave-length than the X rays They bear the same relation to the structure of the nucleus as do the ordinary optical and X-ray spectra to the structure of the electronic system of the atom, but there is this one point of difference The optical and X ray spectra can conveniently be studied for a series of elements because the process of excitation is under control, but it is only in a few isolated cases that it has yet been possible to excite a nucleus by external agencies to emit characteristic radiation Some of the radioactive bodies, however, emit these radiations spontaneously, since the process of disintegration leaves the newly formed nucleus in an excited state and able to emit its characteristic radiation The nuclear spectra have therefore only been examined in detail for those radioactive bodies which happen to emit them, and it has been impossible as yet to find any general laws governing the arrangement of these spectra by noting the similarities in the spectra from a succession of different nuclei

The result of this was that, until a few years ago, while there was a great deal of information about the nuclear spectra of several radioactive bodies, it was still impossible to associate this with any definite feature of the structure Recently the position has changed greatly, and it now seems possible to view in the nuclear level systems which can be deduced from the γ-ray measurements the characteristic stationary states of α-particles or protons in the nucleus, and to associate such level systems directly with the ground states deducible from other evidence

METHODS OF INVESTIGATING THE γ-RAYS

A simple method that was of great importance in the early days of radioactivity was to investigate the absorption of the radiation emitted by a particular body by placing a radioactive source at some distance from an electroscope and observing how the ionisation decreased when successive sheets of some material such as aluminium or lead were interposed It was frequently possible to analyse the resulting absorption curve into a series of simple exponential curves, and thus to obtain a general idea of the different components of the complex radiation Methods such as this could never yield very precise information, and they have now been superseded by more accurate methods

The crystal method, in the forms used for X rays, has been applied with considerable success to γ rays [1] In one respect the technique is simpler, since in place of the X ray tube with all the apparatus necessary to run it, it is only necessary to use a fine tube containing the radioactive material, but in other respects the experiments are far more difficult Owing to the very short wave length, of the order of 40 X U to 4 X U , the glancing angles are extremely small, and not only is the adjustment of the apparatus considerably more difficult but it is also impossible to measure the wave length with much accuracy Further, in comparison with an X ray tube, the normal amount of radioactive material constitutes an extremely weak source of radiation As a result it has not yet been possible to push this method when using photographic registration beyond 16 X U Recently Steadman [2] has devised an arrangement, using an electrical counter in place of a photographic plate, which may overcome some of these difficulties

The method which has given us most of our information is based on the photoelectric effect The general principle is very simple and is as follows [3] A tube containing the radioactive body, the γ-rays of which are under investigation, is placed inside a small tube of some material of high atomic weight, such as platinum In their passage through the platinum, the γ-rays eject groups of photoelectrons the energies of which are connected with the frequency of the γ rays by the Einstein law Thus the γ ray of frequency ν will lead to the ejection of a series of groups of electrons of energies $h\nu\ K_{Pt}$, $h\nu\text{-}L_{Pt}$, etc , according to whether the conversion occurs in the K, L, etc , state of the platinum atoms This electronic emission can be separated out into a corpuscular spectrum by the usual method of semicircular magnetic focusing It is usual to register these spectra photographically, and there is not a great deal of difficulty in analysing them and deducing the corresponding γ-rays, since in most cases it is only the electronic group from the K level which is sufficiently intense to give a detectable effect The general application of the method is greatly limited by the fact that the photographic impression of the groups of electrons always shows as a broad, rather diffuse band The reason is that, although the photoelectrons are ejected from the platinum atoms with sharply defined energies, only those from the surface

* Substance of two lectures delivered at the Royal Institution on Nov 4 and 11

of the tube actually emerge with their full velocity. Those from the lower layers are retarded in their passage out, and cause the diffuse character of the band.

Fortunately, the radioactive atoms themselves provide us with much more favourable opportunities for observing this photoelectric conversion, by what is termed internal conversion. This is by itself an extremely interesting phenomenon, and will be referred to in detail later. For the present purpose it is convenient to describe it as follows. When a radioactive nucleus emits a quantum $h\nu$ of radiation, this does not always escape as such from the atom but may be absorbed by the electronic structure of the atom in its passage out. This internal conversion follows the usual photoelectric laws, and thus a radioactive body which emits γ-rays will also emit a corpuscular spectrum similar in every respect to that coming from the platinum tube already mentioned, except that the energies are now $h\nu - K_{rad}$, $h\nu\ L_{rad}$, The result is in principle in no way different from the previous case where the γ-rays were converted in the platinum, but the importance of this phenomenon for determining the wave length of the γ rays depends on the following facts. If a normal amount of radioactive material is deposited on the surface of a fine wire, the actual number of atoms is so small that the layer is in general less than one atom deep. The electrons liberated by this internal photoelectric effect therefore all escape with their full energy and give extremely sharp lines on a photographic plate, in striking contrast to the broad bands obtained by the normal external photoelectric effect. There is the further advantage that the probability of this internal conversion is so great that measurable lines can be obtained with far shorter exposures than by the other method, and the effects of γ-rays are detectable which are so weak as to be quite unattackable by the other method.

The γ-rays of many radioactive bodies have been analysed by this method, and the main features of the characteristic nuclear spectra are known. The accuracy with which the frequencies can be determined is, however, considerably lower than that realised with X-ray spectra. Even in the case of the bodies radium B and radium C, which have been extensively investigated, the relative frequencies are probably not known to much better than one part in five hundred, and the absolute error may be greater. The chief cause for this lies in the difficulty of obtaining a homogeneous magnetic field over a large area.

INTENSITIES OF THE γ-RAYS

An important method[4] of investigating the intensities has been developed by Skobeltzyn, based on the Compton effect of the γ-rays. A narrow pencil of γ-rays is allowed to pass through an expansion chamber and the recoil electrons liberated by the Compton effect of the γ-rays are observed in the usual manner. In addition, a magnetic field parallel to the axis of the chamber is applied at the moment of expansion, so that the tracks of the recoil electrons are curved by an amount depending on their velocity. By observing both the curvature and the direction of emission of the recoil electrons, it is possible to associate each electron with a γ ray of definite frequency. A statistical study is made of the relative number of the recoil electron tracks, and from a knowledge of the general laws of scattering it is possible to deduce the relative intensities of the γ-rays.

Owing to a variety of experimental causes, the resolution of the method is not very high, and the effect of two neighbouring γ-rays cannot always be clearly separated. This disadvantage, however, is far outweighed by the definiteness of the results about the intensity distribution throughout the spectrum, and by the fact that the method detects weak γ rays equally efficiently as strong γ-rays. The interpretation involves a knowledge of the laws of scattering, but there is both a reasonable theoretical foundation and internal evidence from these experiments which combine to render the uncertainties due to this cause of little importance at present.

The photoelectric method has been applied to determine the intensities of the γ rays by Ellis and Aston[5]. The corpuscular spectra liberated from the radioactive atoms themselves by the internal conversion are clearly of no use in this connexion, since the relative intensities of the groups depend upon the unknown laws of internal conversion. If, however, the corpuscular spectrum ejected from platinum is observed, we are concerned only with the normal photoelectric effect. Supposing that the X-ray absorption results could be extrapolated to the γ-ray region, it would then be possible to deduce the intensities of the γ-rays from the intensities of the corresponding electronic groups. It is, however, precisely this point which is doubtful, and the accuracy of this method is at present limited by the accuracy of the empirical formula which it was necessary to assume for the photoelectric method. The method, however, has one extremely important advantage, which is, that if a γ-ray is sufficiently intense to give a measurable corpuscular group, then the intensity of this group can be determined independently of neighbouring weak γ-rays. It will be seen that these two methods are really complementary, one supplying the deficiencies of the other. The γ-rays of radium B and radium C are the only ones that have yet been intensively investigated, but the results seem consistent, and we know not only the general distribution throughout the spectrum but also the individual intensities of all the strong γ-rays.

The results that have just been mentioned referred to the relative intensities of the γ-rays, and in the analogous case of X-rays or optical spectra this would be all that could be stated. However, in the case of the radioactive bodies it is possible to define and to deduce the absolute intensities. This depends upon the fact that the process of excitation is due to the disintegration of the atom. When a nucleus disintegrates, the departure of the disintegration particle, α or β, may leave the nucleus

in an excited state, and its subsequent return to its normal state is the cause of the emission of the γ-rays The γ-rays are, therefore, emitted only after this disintegration, and it is possible to define the absolute intensity of a γ-ray as the average number of quanta emitted per disintegration It follows that the absolute intensity of any γ-ray cannot be greater than unity The simplest way of deducing these absolute intensities is to make use of the measurements of the total amount of energy emitted in the form of γ-rays Knowing both the frequencies and the relative intensities of the γ rays, it is easy to calculate the average number of quanta of each frequency emitted per disintegration This further step has already been carried out for the γ-rays of radium B and radium C

If we now review the information that we possess about the γ-rays of radium B and C and anticipate that which we shall no doubt in time possess about the rays of other bodies, it will be seen that on the whole it compares very favourably with that available about X-ray spectra The accuracy of the wave-length determinations is certainly much lower, but we have this important information about the absolute intensities For example, a prominent γ ray of radium C has a wave-length of 20 2 X U, which may be in error by one part in five hundred to even one part in three hundred, but on the other hand, we can say that a quantum of this radiation is emitted by the nucleus on the average twice in every three disintegrations

APPLICATIONS TO THE STRUCTURE OF THE NUCLEUS

The preceding account will have shown the extent to which the spectroscopy of the γ-rays has advanced Its application to the problem of nuclear structure is only at the beginning, but it is already possible to indicate the possible lines of advance

It has been realised for some time that there were many examples of combination differences between the frequencies of the γ-rays from any one body, and that this indicated, what was otherwise probable, that the γ rays could be associated with a nuclear level system Little progress, however, was made with this idea for several years, due to the realisation of the difficulty of associating such a level system with any specific part of the nucleus In the nucleus there are α particles, protons, and electrons, and in general any of these particles might be the emitters of the γ-rays This question is still open, but there is now sufficient evidence to make it reasonable to try the hypothesis that the γ-rays are emitted by transitions of α-particles between stationary states in the nucleus

The theories of Gamow and of Gurney and Condon[6] have shown that we may regard the process of emissions of an α-particle as due to the gradual leak of the wave function through a potential barrier An extremely important result of this view is that the energy of the α-particle outside the atom, which can of course be measured, is the same as the energy of the α-particle in the stationary state in the nucleus which it occupied before the disintegration For example, the α-particle from radium C is found to be emitted with an energy of 7 68 million volts We therefore deduce that in the radium C nucleus there is an α particle level with a positive energy of this amount Such a level gives a natural basis on which to build the level system deducible from the γ-rays We imagine that as a result of some internal nuclear arrangement an α particle is excited to one of certain higher states, and that from these states it arrives at the ground state by emitting γ rays of frequencies corresponding to the energy differences It now follows, however, that if an α-particle can leak out through the potential barrier from the ground level, it can do so still more easily from the excited levels We should therefore expect to find a certain number of high speed α-particles corresponding to these modes of disintegration

The existence of such long range α particles has of course been known for a long time, and in fact many tentative suggestions have been put forward associating the energy differences of the groups of α particles with the frequencies of the γ rays The present day point of view, however, goes much further than this, since it predicts definite relations between the intensities of the γ rays and the number of long range particles That such a relation must exist can be easily seen in the following way Suppose that on the average out of every thousand disintegrations there are n cases where an α particle is excited to a certain state, the rate of leak through the potential barrier is given to a fair approximation by theory, and the probability of the nuclear transition can at least be estimated We are therefore able in terms involving only the unknown quantity n to write down the number of long range α-particles we should expect and the number of quanta of radiation Both these quantities can also be measured, perhaps not with a very high accuracy, but yet sufficient to see whether there is an agreement with theory or not

This is really a stringent test for the theory, because although the theories of the probabilities of nuclear transitions are necessarily tentative, any adjustment which proved necessary for one γ-ray must also apply to all the others By arguments of this type Fowler[7] has been led to associate one excited α-particle level of the radium C nucleus with the corresponding nuclear transition formed from the β ray spectrum It seems likely that this line of investigation will lead to definite and valuable results It is of course quite probable that several nuclear transitions will not be able to be associated with long-range α particles, but it would then be possible to draw the important conclusion that these transitions were due to protons or α particles of small positive or of negative energy

INTERNAL CONVERSION

Reference was made above to internal conversion and it was pointed out that groups of electrons are ejected from the K, L, M states of radioactive atoms with just those energies that they would have if radiation were emitted from the nucleus but was absorbed photoelectrically before it escaped

It has been frequently pointed out that there was no need and, in fact, no justification to assume that in this case the radiation was ever actually emitted at all[8] All that could be truly inferred from the experimental results was that an excited nucleus could either emit its excess energy as radiation or had some means of transferring this energy to the electronic structure of the atom

On the old quantum mechanics, it was difficult to imagine any method other than that of radiation transfer, but the wave mechanics suggests that there is a far more intimate connexion between the nuclear particles and the electronic structure The wave functions of the particles in the nucleus will extend out to a certain extent into the electronic region of the atom, and conversely the electronic wave functions will exist throughout the nucleus As a model, we may think that every electron in the atom occasionally passes right through the nucleus, and that a nuclear particle might sometimes for a very short time be found to be actually outside the nucleus

We have thus no difficulty in seeing, in a general way, how the nuclear energy might be transferred to the electronic system by a direct collision process Which process, radiation or collision, is predominant can only be settled by experiment, and the answer given by experiment in this case is fortunately unambiguous The measurements of Ellis and Aston[5] of the extent of this internal conversion and of the way in which it depends on the frequency of the associated radiation show clearly that the behaviour is incompatible with the radiation hypothesis, and we are thus led to conclude that the collision process is the most important It will be seen that this process is really a collision of the second kind, between an electron and an excited nucleus

The peculiar interest of this phenomenon lies in the fact that it represents an easily measurable example of direct interaction between the nucleus and the electronic system There are several other cases where the interaction between the nucleus and the electronic system must be taken into account, but only in order to give the finer details The importance of the phenomenon of internal conversion is that the entire phenomenon, even to its first approximation, depends upon interaction, and that no approach can be made to it with a simple point nucleus

However, quite apart from the intrinsic interest of this interaction, the phenomenon of internal conversion seems likely to provide valuable information about the stationary states in the nucleus The quantity that can actually be measured, the internal conversion coefficient, is the ratio of the probabilities of occurrence of this collision of the second kind and of the nuclear radiation transition The latter is determined mainly by the energy difference of the initial and final states, whilst the absolute energies are involved in the former In a general way it can be seen that the internal conversion should lead to a classification of the levels responsible for the γ-rays, or, in other words, should enable the γ rays to be associated with a definite part of the nucleus

While but little has yet been accomplished along these various lines of investigation of the nuclear levels, it is certainly true that the most difficult step has already been made The problem can now be clearly envisaged, and definite lines of work proposed which seem likely to lead to results The way appears open to an experimental investigation of certain radioactive nuclei, and to an interpretation of the experimental results in terms of nuclear phenomena

An Institute for Experimental Research in Surgery

THANKS to the munificence of Mr George Buckston Browne the Council of the Royal College of Surgeons of England will be able to build, equip, and maintain an Institute for Experimental Research in Surgery, to be known by the donor's name For the building and maintenance of such an Institute, and for the endowment of experimental research, Mr Buckston Browne has given £50,000, with a promise to make further additions until a total of £100,000 is reached

This munificent gift will give England what she now lacks—an institute where surgeons can carry out experimental research bearing on their art The Institute is part of a scheme which was initiated by the Council of the College of Surgeons some years ago, when it equipped laboratories for surgical research in connexion with the Museum in Lincoln's Inn Fields The workers now engaged in these laboratories have found that their investigations are crippled by the lack of a biological station or farm in the country where experimental animals can be maintained and observed under the best conditions Mr Buckston Browne's generosity makes the completion of the Council's scheme now possible

It will be remembered that three years ago Mr Buckston Browne acquired Down House, Kent, from Prof C G Darwin, F R S, and after restoring and endowing it, presented it to the British Association to be preserved as a memorial to Darwin, and for such scientific purposes as the Council of the Association might determine It was Mr Buckston Browne's original intention to establish the Institute which is to bear his name on the grounds attached to Down House, but certain circumstances compelled an alteration of this plan The chief of these was that the land lying to the west of the Down property and flanking

Darwin's 'sand-walk' was to be opened up for building purposes To save the adjacent fields from being built over, Mr Buckston Browne stepped in and obtained the freehold of the property —13 acres in extent It is this land which is to be the site of the Institute It is possible that arrangements may be made whereby the new Institute and Down House may be linked so as to work together for the advancement of knowledge

Mr Buckston Browne has recalled the fact that John Hunter, the founder of the Museum of the Royal College of Surgeons, maintained a farm at Earl's Court for experimental purposes He hopes that his Institute will be to modern surgeons what Earl's Court farm was to John Hunter

Mr George Buckston Browne, the donor, was born in Manchester in 1850, the only son of a well-known medical man—Dr Henry Browne, physician to the Manchester Royal Infirmary and lecturer in medicine to the Manchester Medical School Dr Henry Browne represented the fourth generation of a medical dynasty where son had succeeded father, the founder of the family having been Dr Theophilus Browne, of Derby, who was townsman and contemporary of Dr Erasmus Darwin, grandfather of Charles Darwin Mr Buckston Browne continued the family tradition, representing the fifth medical generation In 1866, at the age of sixteen, he matriculated as a student of the University of London, entered University College, was awarded medals in anatomy, chemistry, and midwifery, and gained the gold medal for practical chemistry and the Liston gold medal in surgery He became a member of the Royal College of Surgeons in 1874, and gained in open competition the house surgeoncy to his hospital (University College Hospital), where he served under Sir John Erichsen He also taught anatomy under Prof George Viner Ellis No one ever trained himself more thoroughly for his profession He is justly proud of the fact that the fortune which he now gives for the endowment of research in surgery has been gained in the zealous pursuit of his chosen profession

Obituary

Sir Andrew Balfour, C B, K C M G

THE death of Sir Andrew Balfour on Jan 30 at the early age of fifty-seven years has deprived the world of one it can ill afford to lose His remarkable knowledge of tropical medicine and hygiene, the result of years of practical experience in the field, research in the laboratory, and intensive study of the literature of the subject, had fitted him more than any other to be a leader and adviser in any movement concerned with the health of our great empire Physically he was a powerfully built man of striking appearance, with open, clean shaven face, searching blue eyes, and determined jaw, and these attributes, combined with a remarkable personality embodying unbounded energy, enthusiastic devotion to duty, absolute honesty of purpose, and an irresistible appeal, brought him not only to the high position he held in his profession, but also at the same time into the hearts of everyone who knew him His solicitude for the welfare of all, both high and low, who worked with him, and the personal interest he took in the aspirations or difficulties, whether great or small, of anyone who came to consult him, endeared him to a host of friends and admirers From his early days he threw himself with fiery zeal into all he undertook to do or say

As first director of the Wellcome Tropical Research Laboratories in Khartoum and medical officer of health of that city, and later, sanitary adviser to the Sudan Government, Balfour placed the medical and health services of the Sudan on a sound scientific basis Later, he established the Wellcome Bureau of Scientific Research in London, and commenced a graphic museum of tropical medicine which has developed into the Wellcome Museum of Medical Science Finally, he directed the building and organisation of the London School of Hygiene and Tropical Medicine, a most difficult task, which brought him to the end of his career The Great War found him with the Medical Advisory Committee before and after which he made various tours of inspection in tropical lands

Outside the particular sphere of his life's work, Balfour was an omnivorous reader, but biography, travel, and adventure pleased him most He was a life member of the Stevenson Club in London and Edinburgh, and took an active part in its proceedings What appears to be only a few months ago, he gave one of his characteristic lectures, which in his modesty he entitled a " Gossip about Robert Louis Stevenson He even found time to write books himself—books of adventure in his early day, such as ' Cashiered, and other War Stories ", " By Stroke of Sword ", " The Golden Kingdom ", and later, books and articles on public health and preventive medicine Some of his articles, such as those collected in book form as " War Against Tropical Disease ', were of a semi popular nature and appealed to a wide public

Balfour was an inspiring lecturer He never failed to hold an audience by the charm of his language, the graphic pictures he would draw of what he had seen in his travels abroad, his earnest condemnation of what was bad and praise of what was good, and the sudden outbursts of wit and humour To prepare his lectures he took endless trouble, which was often not apparent to those who listened to the easy flow of speech, always tinged with an accent indicative of his Scottish descent, of which he was supremely proud In conversation, with his remarkable knowledge of many subjects, he had no equal, and, when in the mood, would recount his experiences or tell stories in a manner to fascinate his listeners for hours

No account of his life would be complete without a reference to his passion for Rugby football A former Scottish international, he remained

throughout an enthusiastic supporter of the game which gave him his most inspiring relaxation He championed the Scottish teams in all their contests, which he frequently attended, and at the time of his death was president of the Scottish Rugby Union He loved to ride a horse, a form of exercise too seldom available, while shooting and fishing found their place in his general keenness for sport when opportunity occurred His was a life crowded to the full He did not know how to spare himself, though at times he felt the burdens which his devotion to tropical medicine and hygiene and his good nature prevented him from refusing No wonder that a few days before his death he wrote to a friend "My own life has been such a rush"

Andrew Balfour, or simply Andrew as he was to many of his friends, was born in Edinburgh on Mar 21, 1873 His father was a practitioner who brought up his family strictly according to the old Scottish tradition, and sowed the seeds of character which remained ever rooted in his son That such upbringing was not unnecessary to curb the spirit of adventure in the young is well illustrated by the behaviour at family prayers, where one or other, during the father's pleadings, would, at the risk of severest chastisement, make a silent circuit of the room from chair to chair From George Watson's College, Andrew passed to the University of Edinburgh, where he graduated M B, C M, in 1894 For a short time he joined his father in medical practice, but, as he said himself, this was not his "line of country" Accordingly he went to Cambridge in the following year with the intention of devoting himself to public health He took his D P H in 1897, and in 1898 his M D with a gold medal at Edinburgh with a thesis on the pollution of water by toxic dye-stuffs Finally, in 1900 he obtained the B Sc in public health During the South African War, 1900 1901, he served as civil surgeon, gaining the medal with three clasps A severe attack of typhoid fever brought him back to England more firmly convinced than ever that public health was to be his life's work

The establishment by Mr Henry S Wellcome in 1902 of the Tropical Research Laboratories at Khartoum and Balfour's appointment as director gave him his first great opportunity Not content with developing the laboratories, which would have been sufficient for a less energetic man, he undertook also the work of medical officer of health, and in a few years converted Khartoum, a former death-trap, into a healthy city At the same time, from his laboratories at the Gordon College, he showed not only those around him but also the whole of Africa, and, indeed, the whole world, through his well-known reports, what organised research could do to improve the health of the tropics His sanitary rounds were made on horseback in the early morning, while the rest of the day was spent at research in the laboratories, and this routine continued in spite of the terrible heat and periodic sand storms which smothered all in dust As a correspondent, closely associated with him in his Sudan days, wrote "All this he accomplished in virtue of his combative, virile, truth loving, honest personality" Occasional trips up the Nile and its tributaries gave him opportunities for observation on the diseases of the native tribes and their domestic animals This convinced him of the utility of a floating laboratory which could take the facilities of modern research into the heart of the country, and again through the munificence of Mr Wellcome such a laboratory came into being It was ever Balfour's hope that similar floating laboratories would be established on other great tropical rivers of the world On one occasion his research laboratories were almost completely destroyed by fire, during which he displayed the greatest daring in saving his records from the flames

In research, Balfour devoted himself chiefly to the blood and its parasites, describing a number of new forms The greater part of his time during several years was spent in investigating spirochætosis of fowls, and he became a convinced adherent to the view that spirochætes have a granular stage in their life history He spent many hours studying these organisms by dark field illumination, and actually saw, or thought he saw granules thrown off 'like drops of water from a dog's tail" One of his best papers was on fallacies and puzzles in blood examination

In 1913, leaving behind many who had learned to respect and love him, Balfour came to London to establish the Wellcome Bureau of Scientific Research Here he exhibited the same qualities which brought him fame in the Sudan The laboratories soon became recognised as one of the centres of medical research in London and—with Balfour, with his world wide reputation, as their head—as a bureau of information where all and sundry were sure of a welcome and of obtaining the latest views and facts regarding diseases and health problems in the tropics In the year of the foundation of the Bureau he extended his experience by a tour of the northern States of South America and the West Indies

The outbreak of the Great War made him restless to be doing something for his country, and to prepare himself for any emergency he entered into training with the Old Boys' Corps In 1915 he was in France, and later in the same year, with the rank of Lieutenant-Colonel, a member of the Medical Advisory Committee in the Near East In 1916, as president, he went with the Committee to India and Mesopotamia During a few months' leave in England in 1917, which might well have been spent in rest, having realised from personal experience the want of a concise account of tropical diseases for medical officers, he undertook the task of writing for the War Office a small book entitled "Memoranda on Medical Diseases in Tropical and Sub-Tropical War Areas" He was able to see the book through a second and third edition, and its success is proved by the recent appearance of the fifth edition The value of this book to medical officers in the War, most of them untrained in tropical medicine, cannot be over-estimated.

In 1917 Balfour was appointed adviser to the

Inspecting Surgeon-General, East Africa In 1918 he arrived in Egypt to undertake the presidency of a Public Health Commission to reorganise the public health service of that country Later in the same year, at General Allenby's request, he visited Palestine to report on the anti-malaria measures adopted there

In 1919 Balfour was again established at the Wellcome Bureau of Scientific Research, picking up the threads of work which had been interrupted by his war service Though settled in London from 1919, he was not at rest for long, for in 1921, at the request of the Colonial Office, he visited Mauritius and in 1923 Bermuda to advise on the health conditions in those islands On his return he took up the directorship of the London School of Hygiene and Tropical Medicine, and threw himself with his accustomed energy into every detail of construction and organisation of this great enterprise For seven years, broken only by short visits to the Sudan, Warsaw, and the United States and all too short holidays, he laboured unceasingly to make his School justify by its teaching and research the generosity of the Rockefeller Foundation, which had made its building possible

Balfour was a member of numerous committees, and from 1925 until 1927 was president of the Royal Society of Tropical Medicine and Hygiene, delivering as his presidential address an inspiring lecture on "Some British and American Pioneers of Tropical Medicine and Hygiene", which well illustrated the amount of research involved in the preparation of one of his discourses Writing of this lecture, a reviewer remarked that "this does something more than impart instruction It admonishes us of one of the serious deficiencies of the ordinary medical curriculum , namely, neglect of the History of Medicine Without a good knowledge of this history of hard work and self sacrifice under difficulties, how shall the old spirit remain alive and the ancient traditions of our profession be handed on unbroken?" It would seem that Andrew Balfour himself had imbibed much of the spirit of these old warriors and had carried on successfully the ancient traditions

In the midst of his great activities, Balfour was in constant demand as a lecturer and writer, and he rarely refused a request His knowledge of his own subject was profound, the result of a system of annotating current literature which he commenced in his Sudan days and continued to the end, though frequently this involved working far into the night Exhausted and overworked, a nervous breakdown brought his labours to a close in 1929 Though he fought his indisposition with indomitable courage, the enforced inactivity became, as he said himself, a vicious circle which prevented his recovery

Balfour received the C M G in 1912, the C B in 1918, and, in recognition of the great work he had done for our overseas possessions, the K C M G in 1930 The University of Edinburgh conferred on him the honorary degrees of D Sc and LL D , the latter of which was also given him by the Johns Hopkins and Rochester Universities of the United States of America He was a fellow of the Royal College of Physicians of London and Edinburgh He married in 1902, and leaves a widow and two sons, the elder of whom is completing his medical studies C M W

WE regret to announce the following deaths

Prof J S Dunkerly, Beyer professor of zoology in the University of Manchester, known specially for his researches on the Protozoa, on Feb 11, aged forty nine years

The Hon Sir Charles Parsons, O M , K C B , F R S , whose name is associated particularly with the development of the steam turbine, on Feb 12, aged seventy seven years

Mr W G Robson, lecturer in natural philosophy in the University of St Andrews, on Feb 16

News and Views

THE British Industries Fair, 1931, was opened on Feb 16, the London Section at Olympia and at the White City, the Birmingham Section at Castle Bromwich This year, for the first time, the catalogues of the two sections are in the same form, each having a classified index in nine languages—English, French, Spanish, Portuguese, Italian, German, Dutch, Swedish, and Danish This feature is an innovation in the Birmingham volume Advance overseas editions of the catalogues were issued on New Year's Day, and were despatched to 10,000 business men and potential buyers in Europe, Africa, parts of Asia, North America, and the east coast of South America, in time for the copies to be received before the recipients departed for the Fair The buyer from abroad can thus look first at the classified index in his own language, from which he can obtain a list of firms exhibiting the particular goods in which he is interested If he desires further information about particular firms, the alphabetical list of exhibitors gives him a description of everything shown by them The Fair continues to show remarkable growth This year both the London and Birmingham Sections have more exhibitors and cover a greater area than in 1930 Moreover, the total area of the Fair is still further increased by the holding of the cotton textile section at the White City, London, for which a separate catalogue is issued The London catalogue, it may be noted, contains descriptions of the exhibits of about 1200 manufacturers and the Birmingham entries bring the total of exhibitors to more than 2000

SINCE it is a British Industries Fair, only British manufacturing firms are permitted to exhibit, and no exhibitor may exhibit articles other than those of his own manufacture The Fair, it may be remembered, is organised by the Department of Overseas Trade and has been held annually since 1915 with the object of attracting important oversea buyers and bringing them into touch with the British producer The Birmingham section was established in 1920 as the

British Industries Fair (Birmingham), and for its organisation the Birmingham Chamber of Commerce is entirely responsible, but the two sections constitute in effect an annual integrated demonstration that Great Britain is still in the forefront of the industrial and manufacturing countries of the world. At Birmingham, the exhibits are those of the heavy industries, chiefly hardware and machinery, including electrical equipment. There is also a gas industries section organised under the auspices of a national committee fully representative of the various organisations in the industry. The London exhibits at Olympia range over a wide and diversified field of the 'light' industries, including, for example, cutlery, jewelry, glassware and china, furniture, toys, leather, scientific instruments, chemicals, foodstuffs, and tobacco. The Empire Marketing Board has an exhibit of Imperial food products and raw materials, cotton textiles being shown separately at the White City. There is also a British artificial silk goods exhibition at the Royal Albert Hall, South Kensington. The stands alone at the four exhibitions occupy no less than 610,000 square feet of space. We hope to give a further account of the Fair, with particular regard to the scientific exhibits, at a later date.

The interest of the Rubber Industry Bill, which passed its second reading in the House of Commons on Jan. 30, is at least as much in the principle involved of a compulsory levy for research purposes as in its intrinsic importance to the rubber industry. The question can scarcely be dissociated from that of the position of other research associations. In its last report the Advisory Council for Industrial and Scientific Research alluded to the financial instability associated with the voluntary contribution system, and expressed the belief that the associations would benefit greatly if some equitable form of levy could be substituted. In the same report, the Advisory Council expressed its disappointment that the results achieved by the various research associations are not being applied and utilised by the industries to a greater extent. In spite of the technical nature of the investigations carried out, there is often a gap between the completion of the investigation and the application of its results in practice. The more progressive firms, organised on scientific lines, admittedly profit most through their ability to utilise a potentially valuable discovery. Every investigation, however, that has important industrial applications tends to raise the general efficiency of the industry. Under modern conditions 'trade secrets' are of minor importance, and an important advance speedily becomes part of the general knowledge and technique in which all units share. To this extent the small manufacturer may derive sufficient benefit to enable him to meet external competition to which he would otherwise succumb.

On the broad issue it is probably true that, in view of the fundamental scientific work which most of the research associations have had to carry out, it is early yet to judge of their utility. We may admit that co-operative research of this kind is under definite disadvantages as compared with that carried out by the large industrial units. That such research associations are doing most valuable work is, however, not disputed by those who are in a position to know, and not the least service they render is in encouraging habits of co-operation and of a scientific outlook in certain sections of industry which, compared with those of other countries, are notoriously backward. Whether a compulsory levy can expedite what is partly educational work has yet to be demonstrated. It should, in the case of the rubber industry at any rate, secure the Research Association from a recurrence of its financial crisis, occasioned by the gradual decrease both of the voluntary contributions and the grants from the Department of Scientific and Industrial Research. The proposed contribution of the manufacturers is limited to one twenty-fifth of one penny per pound of raw rubber purchased, and will provide an average sum of £15,000 per annum for five years. On last year's rubber consumption this would be provided by a contribution of not more than one forty-fifth of a penny.

On Feb. 28 occurs the centenary of the birth of the astronomer Edward James Stone, who, for ten years, was first assistant to Airy at Greenwich, and was afterwards successively Her Majesty's Astronomer at the Cape of Good Hope and Radcliffe Observer at Oxford. Stone also served as secretary of the Royal Astronomical Society, in 1868 was awarded its gold medal, and during 1882–84 served as president. During his ten years at the Cape, he observed the total solar eclipse of April 16, 1874, and the transit of Venus of Dec. 8, 1874, and eight years later was entrusted with the superintendence of the work of the Government expedition to observe the transit of 1882. He also reduced and published the observations made at the Cape by his predecessor, Maclear, and completed a systematic survey of the southern heavens from the south pole to 115° N.P.D. His final catalogue contained 12,441 stars, and it was for this work that he was awarded the Lalande Medal of the Paris Academy of Sciences. Stone died at the Radcliffe Observatory on May 9, 1897.

In the *Quarterly Review* for January is an article by J. M. Hone on "The Royal Dublin Society and its Bicentenary". A Dublin Philosophical Society, with aims similar to those of the Royal Society of London, was founded by William Molyneux, and Sir William Petty had been president, but it had ceased to exist owing to the Irish Civil War which followed the deposition of James II. From its ashes, however, may be said to have sprung the Dublin Society, of which, on its formation in 1731, the public-spirited Thomas Prior was the first secretary. Its interests, the promotion of agriculture, manufactures, arts, and sciences, quickly made the Society of importance. "It attracted to itself", said Lecky, "a considerable number of able and public-spirited members, and it was resolved that each member, on his admission, should select some particular branch, either of natural history, husbandry, gardening, or manufacture, should endeavour as far as possible to make himself a complete master of all that was known concerning it, and should

draw up a report on the subject" Granted a charter in 1750, the 'Royal' title was assumed in 1820 For many years the Society had as its house the Dublin mansion of the Duke of Leinster, but this was taken over in 1923 by the Free State and converted into Parliament buildings, and the activities of the Society are now all concentrated at the fine premises at Balls bridge With a variety of interests to serve "the main work of the Society has been, and is still the promotion of the agricultural interests of the country"

To choose a popular, though maybe difficult subject, to invite contributions thereon from well qualified experts, then to stage a discussion in the inspiring setting of an 'exposition', congress, or the like, is a truly American custom and one which, though by no means contrary to academic or technical policy in Great Britain, is perhaps not quite so frequently in evidence here as it might be The Institution of Petroleum Technologists sponsored such an event on Jan 13, and thereby added what has long been wanted to complete the already detailed American picture of salt technology in its relationship to petroleum—the Eurasian evidence Not that European scientific workers have been backward either in their study of salt bodies, in their presentation of theories of more universal application, or in their published views but to some extent the Gulf Coast occurrences have tended in the past to sway opinion (largely by the volume and detail of publication devoted to the subject, also influenced by the magnitude of modern geophysical explorations in that region), and it was time that the even balance should be restored

THAT we yet have much to learn of this fascinating subject, and that North Germany, Rumania, Persia, and even lesser known regions in the remoter parts of Asia have much to teach us, especially in connexion with salt oil association, is generally conceded, so that the papers presented in London were timely J Romanes discussed the salt domes of North Germany, Dr G M Lees dealt with some depositional and deformational problems of salt, F G Clapp contributed what we may perhaps term the 'liaison' paper on the Gulf Coast, without which no discussion of natural salt bodies would seem complete, J V Harrison described the salt domes of Persia, probably the classic region of visible saline achievements, Dr A Wade dealt with intrusive salt bodies in coastal Asia, South West Arabia, E de Golyer directed attention anew to the origin of Gulf Coast salt domes, L Owen brought forward some 'moot points' in current theories, Dr C Schmidt wrote on the salt dome area of Celle, Germany, while C Sundberg gave an account of recent geo-electrical methods

THE centenary of the death of Henry Maudslay, the eminent mechanician and engineer, which was noted in NATURE, Feb 14, p 245, was commemorated on Sunday, Feb 15, by a special service in St Mary's Church, Woolwich, in which Maudslay was married and in the churchyard of which he is buried The service was conducted by the Rector of Woolwich, Canon A M Pickering, and was attended by the Mayor of Woolwich, Councillor Miss G E Walters, members of the Borough Council and various societies, and by representatives of the Maudslay family During the service, Mr F Carnegie Superintendent of Woolwich Arsenal, in which Maudslay began work at twelve years of age, gave an address on the work and character of Maudslay, making especial reference to his improvements in the lathe and their great influence on the development of machine tools Though Maudslay's life was mainly spent in London, he always retained a great affection for his native borough, and it was therefore only fit that Woolwich should honour his memory After the service, the mayor, on behalf of the Newcomen Society, laid a wreath on Maudslay's tomb In works of reference the date of Maudslay's death is given as Feb 14, but the date on the monument is Feb 15 In view of the fact that the monument commemorates other members of the family and that it was erected soon after Maudslay's death, it may be taken that Feb 15 is the correct date

THE short wave broadcasting and wireless telephone and telegraph duplex station which has been supplied by Marconi's Wireless Telegraph Company to the Vatican City, and was formally inaugurated with a Latin speech by His Holiness the Pope on Feb 12, has a world wide range In its main features, the transmitter follows the design of the Marconi short wave high speed beam transmitters, which are used in the British Imperial beam stations, and it was manufactured at the Marconi Works at Chelmsford The complete installation consists of four main panels, designed for telephony and high speed telegraphy on either 19 84 or 50 36 metres On telephony the transmitter is rated to deliver from 8 to 10 kilowatts of unmodulated carrier wave energy to the aerial feeder system, the output depending slightly on the wave length used On continuous wave telegraphy the rating is from 13 to 15 kilowatts to the aerial feeder A special Marconi type of vertical short wave aerial is used for transmitting, there being a separate aerial for each wave length The transmitting room is situated in a part of the grounds in the Vatican which is surrounded by a Roman wall 45 ft high, while the masts, 200 feet in height, are placed outside this wall In order not to destroy the amenities of the Vatican gardens, a tunnel 141 feet long has been constructed under the Roman wall to accommodate the feeders connecting the transmitter with the aerial A special receiver secures good telephone and telegraph duplex communication between the Vatican City and any part of the world, telephony being possible from any telephone installation in the Vatican City This receiver is situated in one of the rooms of the transmitting station and utilises a vertical aerial placed at a distance of only a few yards from the sending aerial and suspended from the same triatic

IN *World Power* for February an interesting account is given of the South Scotland Electricity Scheme (1930) The area covered by the scheme is 4308 square miles and the population is nearly 256,000 The stations selected by the Central Electricity

Board for operation are a thermal station at Galashiels and five water power stations in Galloway Little of this district has been developed electrically, but much of it consists of forest and moorland It is hoped that by 1935 the water power stations will develop 102,000 kilowatts It is anticipated that much of this power will be absorbed in the Central Scotland and North West England areas The construction of the water power stations may be postponed, however, unless the iron and steel, coal, and shipbuilding industries in Central Scotland and the cotton industry in North West England improve The operation of the water power stations is primarily intended to help the supply at times of 'peak' load The commissioners have planned an extension of this system so as to connect it with the North East England Scheme at Newcastle It is very desirable that such a line should be constructed as soon as possible, owing to possible future requirements of the London and North Eastern Railway The northern district of Northumberland, which is without an electricity supply, could also be served Although this is desirable, it does not seem attractive at present from the financial point of view The capital charges of the water power stations are heavy It is estimated that the cost to the Board will vary from 0 38*d* per unit in 1934 to 0 34*d* per unit in 1943 The average price to the consumer will be less than 0 5*d* per unit

On Feb 11, Mr E L Gardiner gave a lecture to the Television Society on "The Stenode Radiostat and its Application to Television" This type of transmission has not yet been tried experimentally, but from a mathematical consideration of the problem it appears possible to generate a signal to which only the stenode will respond, and which, even when superimposed on ordinary transmissions, will cause no interference In its simplest form the stenode radiostat is a very sharply tuned receiver A wireless receiver with a very peaky resonance curve, however, gives a reproduction which is woolly, due to the attenuation of the higher frequencies consequent on the sharp tuning To correct this, the low frequency amplifier in the stenode is designed to emphasise the higher frequencies, so that the final output is fairly even throughout the audible range Sharp tuning in a straightforward circuit causes, among other difficulties, instability, and to overcome this the superheterodyne principle is used With this circuit selectivity can be made as keen as is necessary, simply by reducing the frequency of the intermediate amplifier, and this without altering the form of the resonance curve By using the superheterodyne circuit with six valves and comparatively simple tuning arrangements, a satisfactory separation of stations only two kilocycles apart can be secured For a similar result with a band-pass filter circuit at least six ganged circuits are necessary A better method of employing the stenode principle is to insert a quartz crystal, cut to resonate at the required frequency, in the circuit of the intermediate amplifier This, due to the fact that the crystal acts as a very high resistance to all frequencies but its resonant frequency, gives a much sharper tuning, and makes it possible to get almost any degree of selectivity.

In his Friday evening discourse delivered at the Royal Institution on Feb 13, Prof F L Hopwood discussed ultra sonics or inaudible sound Sound is, of course, produced whenever a vibrating body is placed in a material medium, whether the latter is a solid, a liquid, or a gas For sounds to be audible, the vibrations must not only be of sufficient amplitude, but also their frequencies must lie within the range 20-20,000 Disturbances of the same type as sound-waves but having frequencies exceeding 20,000 vibrations per second are termed ultra sonic Remarkable effects are obtained when sound waves of great intensity, and frequency of about half a million, are generated in an oil bath by means of a quartz crystal set into resonant vibration by a thermionic valve oscillator Acoustic radiation pressure exerted on the free surface of the oil may raise in it a mound several centimetres or even inches in height, and cause it to erupt droplets like a miniature fountain On plunging vessels of appropriate form into this mound of oil, vibrations of great intensity may be communicated to the walls of the vessels, or, through the walls, to liquids contained in them Following the methods of Langevin, Boyle, and Wood and Loomis, demonstrations were given of reflection, refraction, and interference of sound waves of short wave length, the production of bubbles and expulsion of dissolved gases from liquids, acoustic distillation, transverse vibrations in solids accompanied by anomalous movements of dust particles, flocculation of suspended matter and production of emulsions, acceleration of chemical action, pronounced thermal effects, remarkable effects produced on plants, bacteria, muscle nerve preparations and on living organisms such as planaria and fish

In view of the pessimistic opinions often expressed regarding some of our industries, the figures relating to steel production recently given by Mr W B Jones, at the first annual general meeting of Steel Industries of Great Britain, Ltd, are of considerable interest One aspect of the steel industry is reflected in the total amounts of steel produced in Great Britain, Western Europe, and the whole world respectively Taking the three years 1913, 1925, and 1929, the figures for Great Britain were 7,660,000, 7,390,000, and 9,640,000 tons, for Western Europe 25,670,000, 25,440,000, and 34,990,000 tons, and for the world 75,150,000, 88,930,000, and 118,300,000 tons After referring to the disadvantages steel makers suffer from, Mr Jones said, "it is surprising to find how well the British steel industry has stood up against these handicaps" "In 1929, a year in which Western Europe was able to take full advantage of the handicaps in its favour, production of British steel not only reached its highest figure, but the relation of its production to that of itself and Western Europe added together, which in 1913 was 23 per cent, in 1929 was only reduced to 21 6 per cent." Though not referred to by Mr Jones, it may be remarked that Great Britain has to import

a considerable proportion of the iron ore used, in 1928, 11,261,000 tons of ore were produced in the country and 4,439,000 tons imported

THE Pharmaceutical Society's second conversazione was held in the Society's house in Bloomsbury Square on Feb 10 The whole of the premises, including the School of Pharmacy, the library and museum, the pharmacological laboratories, and the research laboratories, were thrown open The council chamber contained an exhibition of portraits of pharmaceutical interest and old pharmaceutical apparatus and equipment Among the exhibits in the laboratories were the following diagrams showing the method of estimating the absorption of calcium through the intestine, growth charts of animals suffering from a deficiency of vitamins, methods of distinguishing between vitamins B_1 and B_2, a demonstration of recent work showing that carotene is changed to vitamin A in the animal body the latest forms of pharmaceutical apparatus under working conditions, army and navy pharmaceutical equipment, samples of crude drugs about to be added to the British Pharmacopœia and the British Pharmaceutical Codex, the use of the quartz lamp for detecting adulterants in drugs, the syntheses of various organic chemical drugs, including camphor, salvarsan, and anæsthesine

THE Council of the National Museum of Wales, in spite of the financial stringency of the times, continues to pursue a strong policy in regard to the erection of the museum buildings Bearing in mind that the Government grant of £50,000 promised in 1928 was conditional on the full building programme of approximately £150,000 being proceeded with, the Council has proceeded with the second portion of the scheme The estimated cost is £81,987 The sums in the hands of the Council are insufficient, but the councillors go forward believing that their countrymen will support them in their endeavours The past financial year brought excellent contributions, amounting in all to £26,767, and Cardiff City Council voted the munificent sum of £21,000, to be spread over a period of seven years A considerable sum still remains to be collected, and during the course of the present year every effort will be made to secure the balance We trust that the effort will be abundantly successful, the Welsh National Museum has set a new standard for museum construction in Great Britain, and the energy, foresight, and faith of the members of its council deserve every encouragement

THE scheme for the award of the "Beit Railway Trust Fellowships for the Two Rhodesias" has now been completed This scheme has been made possible by the provisions of the will of the late Sir Otto Beit and offers facilities for two years' post graduate work for three candidates The fellowships will be tenable at any university or institution, approved by the trustees, in South Africa, Great Britain, the Oversea Dominions, Europe, or the United States of America Each fellowship is valued at £250 per annum if held in South Africa and £375 per annum if held overseas Preference will be given to South Africa, if the suggested course permits The chairman of the advisory board for the administration of these fellowships is the Governor of Southern Rhodesia Applications for information of conditions, etc, with reference to the fellowships (one of which is that the applicant shall have resided in Northern or Southern Rhodesia for three full years prior to application) should be made to the Secretary, Advisory Board, Beit Railway Trust Fellowships for the Two Rhodesias, P O Box No 4, Bulawayo, Southern Rhodesia

THE after shocks of the New Zealand earthquake are becoming less frequent and less violent, though strong earthquakes on Feb 8, 12, and 13 brought down some already damaged houses at Napier A harbour official reports that although the bed of Napier harbour rose during the earthquake it has since subsided gradually It appears to be still about 7 feet above its former level, but coastal steamers will be able to use the harbour, though additional dredging will be necessary The latest reports show that 133 persons were killed at Napier, 71 at Hastings, and 36 elsewhere

MADAME CURIE has been awarded the Cameron Prize of the University of Edinburgh for 1931, in recognition of the important therapeutic advances that have been made in recent years as a result of her discovery of radium

THE Council of the Iron and Steel Institute has awarded the Bessemer Gold Medal this year to Sir Harold Carpenter, professor of metallurgy in the Royal School of Mines, Imperial College of Science and Technology, London The award is made in recognition of distinguished services rendered by Sir Harold Carpenter in the advancement of metallurgical science, and of the valuable research work performed by him in relation thereto

AT the annual general meeting of the Quekett Microscopical Club, held at 11 Chandos Street, Cavendish Square, W 1, on Feb 10, the following officers and new members of committee were elected *President* Mr J Ramsbottom, *Hon Treasurer* Mr C H Bestow, *Hon Secretary* Mr W S Warton, *Hon Reporter* Mr A Morley Jones, *Hon Librarian* Mr C H Caffyn, *Hon Asst Librarian* W P Sollas, *Hon Curator* Mr C J Sidwell, *Hon Asst Curator* Mr R G Evans, *Hon Editor* Mr W S Warton, *New Members of Committee* Mr R G Evans, Mr W J Lloyd, Mr J M Offord, Mr D J Scourfield

WITH reference to the review of his book on "Fourier's Series and Integrals" (Ed 3) which appeared in NATURE, Oct 25, 1930, Prof H S Carslaw has written pointing out that the reviewer wrongly gives him credit for noticing that a certain Wilbraham in 1848 anticipated Gibbs's discovery in 1899 of the property now generally known as "The Gibbs Phenomenon" Wilbraham's paper was cited by Burkhardt in his article on "Trigonometrische Reihen und Integrale" in the "Enc d math Wiss" (Bd 2,

Teil 1, 2 Hälfte, p 1049, 1914), and there is also a reference to the matter in the article by Hilb and Riesz in Bd 2, Teil 3, p 1203 (1924) Prof Carslaw's attention was directed to Wilbraham's paper by Prof G N Watson

A USEFUL statistical summary entitled the "Mineral Industry of the British Empire and Foreign Countries" has been compiled by the Imperial Institute (H M Stationery Office, 5s 6d) The volume includes statistics for 1927, 1928, and 1929, where available, for some fifty minerals Under each heading are given the total production for each producing country, and the imports and exports for all countries Minerals are arranged alphabetically Quantities are given in tons, hundredweights, or pounds The uniformity with which the statistics are given much facilitates use and comparison, and the volume should meet with wide acceptance An appendix gives lists of statistical publications for each State

A CATALOGUE (New Series, No 24) of some 1400 second hand works on natural history, classified under the headings of periodicals and publications of learned societies, zoology, botany, geology, mineralogy, mining, etc, astronomy, chemistry, etc, and Linnæana, has just been published by Messrs Wheldon and Wesley, Ltd, 2 Arthur Street, W C 2

APPLICATIONS are invited for the following appointments, on or before the dates mentioned — An assistant lecturer in the Department of Mathematics and Physics of the Polytechnic, Regent Street —The Director of Education, The Polytechnic, Regent Street, W 1 (Feb 27) A forestry inspector under the Department of Agriculture of the Irish Free State—The Secretary, Civil Service Commission, 45 Upper O'Connell Street, Dublin, C 8 (Feb 27) A lecturer in pathology in the Department of Pathology and Bacteriology of the University of Leeds—The Registrar, The University, Leeds (Mar 2) A male senior lecturer in the Department of Education of King's College, London—The Secretary, King's College, Strand, W C 2 (Mar 6) A chief designer in the Design Office of the Department of Technical Education of the Egyptian Ministry of Education—The Under Secretary of State, Ministry of Education, Cairo, Egypt (Mar 9) A full-time teacher in the Department of Chemistry of the West Ham Municipal College—The Principal, West Ham Municipal College, Stratford, E 15 (Mar 14) A temporary hydrologist and a temporary biologist under the Ministry of Agriculture and Fisheries, for research work in connexion with the survey of new fishing grounds by H M S *Challenger*—The Secretary, Ministry of Agriculture and Fisheries, 10 Whitehall Place, S W 1 (June 1)

ERRATUM —NATURE, Feb 14, p 237, col 2, line 3, for "raise the temperature" read "lower the melting point"

Our Astronomical Column.

Bright Meteor Photographed —The *Journal* of the B A A for January contains a reproduction of an interesting photograph of a bright meteor, obtained on Sept 19, 1930, by E H Collinson at Ipswich The meteor was observed visually by Mr J P M Prentice at Stowmarket From a combination of the two, Mr A King has deduced the path of the meteor, the speed came out 24 m p s, which is 3 m p s less than the parabolic speed The luminous flight began at a height of 79 miles, and ended at one of 54 miles The photograph indicates three explosions, after each of them the track on the plate suddenly widened, and then gradually grew narrow again, the calculated heights at the explosions are 68½, 61, and 58 miles respectively The path produced ended in the sea, 16 miles south east of Brightlingsea The inclination of the path was 52°, and the perihelion distance 0 34 unit The motion was inward Most meteor photographs have been obtained accidentally on plates exposed for other purposes, but Mr Collinson uses a specially constructed automatic camera for the purpose of securing them, he is to be congratulated on this fine result

Pluto —M Mineur, assistant at the Paris Observatory, contributes an article on Pluto to *L'Astronomie* for December, in which he directs attention to the two remarkable relations between the orbits of Pluto and Neptune

(1) Their periods are almost exactly in the ratio 3 to 2 This relation may be rendered quite exact when the period of Pluto is known with great accuracy

(2) They have very nearly a common line of apsides, the perihelion of Pluto being in longitude 223° 14 6′, and the aphelion of Neptune 224° 1 1′, both for the equinox of 1930 0

If they were simultaneously on the apse-line, there would be a type of regular periodic motion, but this is not actually the case It is interesting to note that in the two other pairs of interlocking orbits with which we are acquainted, satellites VI and VII of Jupiter, and satellites VIII and IX of Jupiter, the apojoves of each pair are roughly opposite to each other It is difficult to think that the relationship can be permanent in the case of Neptune and Pluto, as the perturbations that they undergo from the other planets must be decidedly different

Nakamura's Comet —*Bulletin* No 183 of the Kwasan Observatory, Kyoto, gives some more particulars about this comet It was discovered photographically on Nov 13 on plates taken with the 11 cm triplet lens, and was then of magnitude 13 5 Mr Nakamura observed it visually on Nov 16, noting that it appeared fairly sharp and somewhat elongated The following photographic positions are given, presumably for the equinox of 1930·0

			R.A	N Decl.
1930 Nov	13	57635 U T	$3^h 40^m 41 44^s$	18° 53′ 25 4″
	14	51980	3 37 52 69	18 41 1 0
	15	56116	3 34 51 86	18 28 12 5

The parabolic elements deduced from these by Mr Y Sibata were telegraphed to Europe, and have already been published in NATURE

The seconds of R.A on Nov 13 were printed as 14 in the circular, but it is fairly evident, both by comparison with the telegraphed position and by differencing from the ephemeris, that 41 is correct

This comet must have faded very rapidly, as Prof G van Biesbroeck made a careful search at Yerkes Observatory after receiving the telegram, but could not find it

Kwasan Circ, 181, notes that a 25 cm. photographic reflector, focal length 95 cm, has been installed at Kwasan for photographing comets and asteroids

Research Items.

The Eskimo.—Dr. Aleš Hrdlička reports, in the *Forty-sixth Report of the Bureau of American Ethnology* (1928–29), on a journey among the Eskimo of Alaska which lasted from May to September 1926. His object was to make an anthropological survey of the Eskimo, in the hope of filling in some of the gaps in our knowledge of this people which, up to the present, vitiate the conclusions which have been drawn as to their origin and affinities. The conclusions at which it has been possible to arrive are as follows. The Eskimo throughout their territory are one and the same people. The strain is fundamentally related to that (or those) of the American Indian. It is also undoubtedly related to the yellow-brown strains of Asia. In many respects the Eskimo are remarkably alike over their whole territory—in such characters as pigmentation, build of body, physiognomy, large brain, fullness of forehead, largeness of face and lower jaw, etc. They differ in details such as stature, form of head, and breadth of nose. The distribution of these is of some significance, but between east and west, where the extremes are found, there is a regular gradation without significant interruption. This is due not to admixture but to adaptation and differentiation. They suggest a moderate stream of people rooted in Asia of fairly broad but moderately high head, of good medium stature with a mesorhine nose, and other characteristics in common, reaching America from north-easternmost Asia after the related Indians, spreading along the coast until blocked by the preceding Indian tribes, and gradually modifying physically in adaptation to the environment and conditions. The evidence shows that, with the exception of some irregularities, the more highly differentiated and divergent the Eskimo becomes the greater the gap between him and his Indian neighbour. The facts point, therefore, to the original identity of the source from which the Indian, more particularly the latest branches, and the Eskimo were derived, and to the identification of this source with the palæo-Asiatic yellow-brown peoples of lower northern Asia. The differentiation of the Eskimo from this source must have proceeded over a fairly long time, and probably began on the northern coasts of Asia.

Supervision and Morale.—The *Journal of Industrial Psychology* (vol. 5, No. 8) gives an account of an experiment in supervision and morale by Mr. Elton Mayo, the object being to study the effect on employées of controlled changes in conditions of work. Six girl operatives doing standardised mechanical routine work for forty-eight hours a week were selected at random, and placed under test conditions for three years. A supervisor was installed to observe non-experimental influences. Then various changes were introduced, for example, segregation in test room, payment at special gang rate, rest pauses, five-day week, and so forth. The result showed a steady improvement measured in terms of output, which was continued even after resuming original conditions. Contrary to anticipation, it appeared that none of the controlled conditions was significantly responsible for the improvement, which appeared to be attributable to the mental attitude of the workers towards the supervisor. Periodic examinations of blood pressure and pulse rates revealed that a state of equilibrium, not one of constant effort, was that in which the best work was produced; this was equally true in the mental sphere, where the supervisor's tact and capacity for listening sympathetically were important. The details of the investigation, and relevant graphs given, are illustrative of the investigator's thorough work; but the experiment would have been of more scientific value had adequate control groups been described to the same extent.

The Creeper Fowl.—Further genetic experiments by Landauer and Dunn (*Jour. Genetics*, vol. 23, No. 3) confirm their hypothesis that the condition is lethal when homozygous. They have obtained creeper fowls from America, Scotland, Germany, and the Marquesas Islands. Crosses were made between these four strains which indicated that the same mutation is present in each. All the bones of the legs and wings are shortened in this type; the tibia is strikingly bent, and the fibula much enlarged. This condition is inherited as a simple dominant to normal. Breeding tests show that all creeper fowls are heterozygous; when mated together they give about 2 creepers : 1 normal, and about 25 per cent more embryos die during the first six days of incubation than in the case of outcrosses. These homozygous lethal embryos were identified. They show a great retardation in development on the third day of incubation, and a photograph is given for comparison with a normal three-day chick. A small number of these embryos, especially from crosses between different creeper strains or from outcrosses with normals, may develop nearly to the hatching time, but they show a condition of phocomelia similar to that known in man and other mammals. This is apparently the first time phocomelia has been observed in birds.

Scottish Tunicates.—Dr. H. Thompson, in his paper "The Tunicates of the Scottish Area. I." (*Fishery Board for Scotland, Scientific Investigations*, No. 3, 1930), has begun a systematic survey of the tunicates found in the area worked by the research vessels of the Fishery Board for Scotland, with special reference to the distribution and ecology of the species. He fully realises that a knowledge of the live animal with its eggs, larval and post-larval stages is of the greatest importance in classification, and the fact that he has been able in most cases to study each species in this way makes his work specially valuable. He also lays great stress on the proper preservation of the animal, a precaution often much neglected. Certain ascidians are important as fish food. For example, haddock in some districts, such as the Moray Firth, may feed on half a dozen species and at times almost exclusively on *Ascidia scabra*. An exact mapping of the distribution of all animals preyed upon by fish is very desirable. Natural barriers such as a definite change of temperature where two waters meet must affect both the fishes and their food. Indeed, the food is probably one of the most important factors in the distribution of fish. It is shown that there is such a natural barrier at or near a region to the south-east of Iceland, where within a few miles the temperature of the water undergoes a sudden change from boreal to arctic conditions. The haddock on each side of this barrier grow at quite different rates, and the change at any rate in the ascidian fauna is complete. The chief object of the work is to show which species are found under typical conditions. These 'critical' species, or 'test' species are specially studied, whilst others which are able to exist under more varied conditions are of secondary importance. The species are divided into boreal and arctic, and subdivided into boreo-arctic, north, south, east, and west boreal. The systematic part classifies the tunicates into orders, further classifies the sedentary forms, and describes the first order, Ptychobranchia, with the two families Molgulidæ and Pyuridæ.

Culture of Sponges and Oysters.—Two recent parts of Abderhalden's comprehensive "Handbuch der biologisches Arbeitsmethoden" (Abt. 9, Teil 5, Heft 4, Lief. 326, Heft 5, Lief. 333) continue the volume describing the culture and methods of rearing of marine plants and animals. Lief. 326 deals with sponges, cœlenterates, mollusca, and crustacea, whilst the oyster alone occupies Lief. 333. Only a few sponges have so far been reared from the egg, and it is very difficult to find suitable food for them. This is the main problem in the rearing of all marine animals, successfully solved for many forms by the diatom cultures of Allen and Nelson, but there still remain many invertebrates which in their first stages are too small to use these diatoms. In such cases minute flagellates and the active spermatozoa of *Fucus* are recommended. Unfortunately, however, the latter live scarcely longer than a day and so have to be frequently renewed, and cultures of flagellates are not so easy to maintain as cultures of diatoms. Much work is still needed on these points, although it is very interesting to see how much has already been done and how many invertebrates have been reared. Here, echinoderms come first and several species have been brought through all the larval stages on the diatom *Nitzschia*. These have already been described in a former part (Lief. 278). In the present sections both Dr. Hagmeier and Dr. Kandler say much about the rearing of molluscs, most of which must have very minute food in their early stages. Cœlenterates usually require animal food such as Copepod and Cirripede nauplii and other small planktonic forms. Crustacea, such as crab zoeæ, seem to prefer very young larval molluscs and may eat the planulæ of worms and echinoderms. Oyster larvæ form an ideal food for crab zoeæ, the older larvæ eating small crustacea or pieces of shrimp, prawn, or mussel. Vessels and aquaria of all kinds for rearing are fully discussed, and apparatus for collecting the various animals. Commercial rearing is also described, especially with regard to sponges and oysters.

A Natural Species-Hybrid in the Genus *Geum*.—A careful study of the well-known hybrid between *Geum urbanum* and *G. rivale*, which goes under the name of *G. intermedium* and has long been recognised as a natural species hybrid, has been made by E. M. Marsden-Jones (*Jour. Genetics*, vol. 23, No. 3). By crossing the two species experimentally the F_1 generation was found to be practically uniform but not intermediate between them except in three characters. Six of the *rivale* characters were dominant, including the presence of plumose hairs on the styles, anthocyanin in the flowers, and the flowers pendulous, while two *urbanum* characters appeared in the majority of plants. The back-crosses of *intermedium* to both species have been studied, as well as the F_2 generation from the original and the back crosses. The evidence of segregation in many characters is clear; but simple Mendelian ratios were not obtained. The reciprocal crosses between *intermedium* and *urbanum* gave identical results: 4 plants were *intermedium*, 2 *urbanum*, and 88 very like *urbanum*. These hybrids also exhibited a new type of short plumose hair. When a plant of this back cross is selfed, segregation takes place in number of glands, colour of petals, and type of flowers. The back cross *intermedium* × *rivale*, on the contrary, when selfed, shows very little segregation. A colony of such plants was studied at Bradfield, Berkshire, on the River Pang, where this hybrid appears to have established itself and largely replaced *rivale*.

Exploration in East Greenland.—A small expedition aided by the Norwegian Government visited East Greenland in the *Veslekari* under the leadership of A. K. Orvin during the summer of 1929. The objects were largely scientific, and a certain amount of correction of the charts was accomplished between Sabine Island and Davy Sound. The results are outlined, in Norwegian, in *Norges Svalbard- og Ishavs undersökelser, Meddelelse*, No. 11, which also contains a map. One of the important aims of the expedition was to obtain a number of musk ox calves which were to be sent to Spitsbergen, where the musk-ox does not exist at present. In the absence of wolves in Spitsbergen the musk-ox should thrive well in places where grasses are fairly abundant in the vegetation.

Geology of Uganda.—The Annual Report of the Geological Survey of Uganda for 1929 contains many features of unusual interest, one of the most notable being a geological account of a journey from Lake Tanganyika to Entebbe, undertaken by A. D. Combe. A general description of the spectacular volcano Nyamlagira is given, with details of its behaviour during the visit made to its crater. Bombs of olivine-leucitite are recorded from a late Pleistocene volcanic area near Kichwamba, south of the Kazinga Channel. At the other end of the geological column, in the "green-grey rocks" of North Kavirondo, W. C. Simmons finds phonolites with andesites and rhyolites. These ancient lavas are pre-Karagwe Ankolian in age and may correspond with the Ventersdorp of South Africa. Not far away there are phonolites of later Tertiary age. Simmons also adds to his previous contributions some further notes on the petrology of the Bufumbiro volcanic rocks, and points out that the total area over which leucitic lavas predominate is nearly 1500 square miles. A general paper on this important volcanic field and on the nature of its rocks appears in the *Geol. Mag.*, Nov. 1930. Detailed work is in progress, the results of which will be published in a forthcoming memoir. Other research notes in the report record seismic tremors connected with an epicentre near Ruwenzori; the occurrence of nepheline and melilite bearing rocks from near Mount Elgon; heavy mineral suites of Uganda granites; and archæological discoveries of three ages on a site near Port Bell. The report is enriched by a clearly designed and well printed provisional geological map of the Protectorate. The Director, Mr. E. J. Wayland, is to be congratulated on the solid record of achievement that is summarised in this very welcome map.

Carboniferous Rocks of Hook Head.—L. B. Smyth (*Proc. R. Irish Acad.*, 39 B, p. 523; 1930) describes the zonal characters of the Lower Carboniferous (Tournaisian) of the promontory ending in Hook Head, co. Wexford. The Carboniferous rests conformably on the Old Red Sandstone and includes the Cleistopora zone ($K1$, $K2$), the Zaphrentis zone ($Z1$, $Z2$, γ), and the Caninia zone ($C1$, $C2$). The succession closely resembles that found in Pembrokeshire. The echinoids, of which beautifully preserved specimens were obtained by collectors in the last century, appear to have come from the zones $C1$ and $C2$. In the section on palæontology some new species of corals and brachiopods are described.

Artificial Production of γ-Rays.—W. Bothe and H. Becker report in the *Zeitschrift für Physik* for Dec. 3 that a number of light elements—lithium, beryllium, boron, fluorine, magnesium, and aluminium—emit γ rays when bombarded by α-particles. The effect is apparently similar to artificial disintegration with liberation of protons, since the efficiency of production of the γ rays is about the same as that of protons, and the absorption coefficient of the radiation

from boron and beryllium—the latter being the most efficient radiator—about that of the hardest γ-rays from the common radioactive bodies Liberation of protons and emission of γ-rays do not, however, run parallel, nitrogen, for example, gives relatively large yields of protons, but no γ-rays, whilst beryllium gives strong γ-radiation, but is otherwise very stable The hardness of the radiation does not appear to be much affected by the speed of the α particles by which it is excited, and the radiation from boron, at least, is emitted about equally well in forward and backward directions The existence of a hard γ-radiation from polonium, the source of α rays for these experiments, is also reported

A Possible New Spectrum of Helium—In the issue of *Die Naturwissenschaften* for Jan 9, Dr W Grotrian has given a critical summary of Rosenthal's theory of the lines of the solar corona, the principal remaining spectrum of uncertain origin Rosenthal has suggested that these come from neutral helium atoms, in which both electrons have been displaced from their most tightly bound positions, with one always in the orbit next to the innermost On general grounds it would be expected that this system should give rise to a spectrum closely similar to the ordinary arc spectrum of this element, with corresponding lines displaced to the violet This is in fact what is observed with the coronal spectrum, the lines of which can be associated, with little forcing, with strong arc lines which are well known from laboratory work The objections raised by Dr Grotrian to this are serious, but not insuperable, as he recognises by characterising the theory as the first meriting really careful consideration, that the energy of the excited atoms is far in excess of that required for ionisation is only an extreme instance of what has been already established in several spectra obtained from laboratory sources, whilst the absence of the normal helium arc lines and the apparent occurrence of a state of the atom forbidden by the Pauli principle may possibly be attributable to the special conditions of excitation and to a flaw in the theory of the helium atom Dr Grotrian mentions that Rosenthal is attempting to obtain these lines from a discharge through pure helium, but whether this proves practicable or not, it should be possible to test his hypothesis by calculation of the energy of the helium atom in doubly excited states

Thermodynamic Properties of Fused Salts—Three papers in the December number of the *Journal of the American Chemical Society*, by J H Hildebrand, E J Salstrom, and A Wachter, describe experiments on the electromotive forces of concentration cells with fused salts Solutions of lead chloride in lead bromide, lithium bromide in silver bromide, and lead chloride in zinc chloride were used, with suitable electrodes The results show that the variations of electromotive force cannot be explained on the assumption of complete ionisation of the salts, although the authors prefer to consider them from the point of view of the change of interionic forces due to the substitution of one ion by another In the case of lead bromide and lead chloride, for example, a change in the interionic forces due to the replacement of the bromide ion by the smaller chloride ion is assumed The data so far obtained do not allow of a quantitative treatment on these lines, which will be attempted later

Lipase in Olives—It has been known from ancient times that olives, after being gathered or allowed to fall from the tree, are subject to a fermentative process which exercises a deteriorating influence on the oil afterwards obtained Experimental results published by Pantanelli and Verdesca in the *Rendiconti* of the Naples Academy of Physical and Mathematical Science for January June 1930 show that this process consists in acidification of the fatty matter owing to the action of a lipolytic enzyme which accelerates the scission of the glycerides into free fatty acid and glycerol with absorption of water The activity of this lipase increases rapidly as the cellulose structure of the fruit is destroyed by the pressing During the treatment of the olives, the enzyme is transferred from the aqueous magma to the oil, and the more highly acid the oil at the time of crushing, the richer is it in lipase and the more prone to become more acid The hydrolysis of the fat is related to the presence of moisture, which remains emulsified during the operations, and, apart from this, is proportional to the amount of glycerol already formed Hence, the factor determining the course and the intensity of the acidification is the glycerol, as it is the means of introducing water and lipase into the oil

Egg Albumin—The December number of the *Journal of the American Chemical Society* contains two papers on egg albumin The first of these, by J B Nichols, gives the results of ultra centrifuge experiments on crystallised, electro dialysed egg albumin The diffusion constant is abnormal, being six tenths of the value calculated from the sedimentation constant ($4\ 06 \times 10^{-13}$ cm per sec at 30°) and the molecular weight (34,500) The molecule is spherical and of radius 2 17 mμ, it is practically identical in size and mass with that of Bence Jones protein, although entirely different in chemical composition At a *p*H value of 1 16 in 0 1 *N* hydrochloric acid egg albumin is completely denatured and forms a gel, the mean size of the gel clumps corresponding with about seven molecules per particle after three hours The second paper, by Sjogren and Svedberg, is on the *p*H stability region of egg albumin Crystallised electro dialysed material was used, about three months old In the *p*H range the protein is stable and the ultracentrifuge gave a homogeneous molecular weight of 34,200 Below *p*H 4 and above *p*H 9 some of the molecules split into a non centrifugible substance At *p*H lower than 3 the sedimentation increases, indicating aggregation, above *p*H 9 it decreases, indicating the breaking up of the whole material

Atomic Weights of Uranium Lead—Baxter and Bliss, in the December number of the *Journal of the American Chemical Society*, report the value 206 01 for the atomic weight of lead from Swedish kolm (a shale like material said to be an upper Cambrian sedimentary with trilobites) This is the lowest value ever formed, the next being 206 046 obtained by Hönigschmid and Horowitz for lead from Morogoro pitchblende No thorium was found in the kolm ash If Pb^{207} is the end product of the actinium series, on the basis of Aston's results, an atomic weight not less than 206 1 is to be expected for uranium lead In a second paper the same authors report the value 206 195 for lead from a specimen of uraninite from Ontario On the assumption that this is essentially free from ordinary lead, that the relation of Pb^{206} to Pb^{207} found by Aston in bröggerite material, 86 8 to 9 6, is that in which these isotopes are produced from uranium, and that the uranium equivalent of thorium in lead-producing power is 0 38, the average atomic weight of lead in the specimen of uraninite used is calculated as 206 23 The difference between this value and that found experimentally, 206 195, is far larger than the experimental uncertainty. The possibility that Aston's bröggerite lead was badly contaminated with ordinary lead is raised.

Problems of High Tension Overhead Electric Supply Systems

THE setting up of high tension overhead electric supply systems all over Great Britain has brought to the foreground many engineering and scientific problems, the solutions of which are urgently wanted One is the best design for insulators so as to avoid flashover, and another is the best way of preventing the vibrations of overhead transmission conductors In a paper read by Mr P J Ryle to the Institution of Electrical Engineers on Feb 5, both these problems were discussed and partial solutions given

Seven years ago, the Newcastle Electric Supply Co put into operation a 66-kilovolt line which is now nearly a hundred miles long It was soon found out that flashovers occurred in the strings of suspended insulators in industrial areas It was also discovered that they occurred oftener when the line was near a rocky coast than when it was in the neighbourhood of a sandy beach Probably the salt spray was the cause The number of insulators in the supports was increased from five to six, but this had little effect The main cause was traced to the deposits on the insulators Similar troubles have occurred in Germany near lignite (brown coal) power stations, and mention was made of a complete 110 kilovolt system which had to be roofed over owing to the dust from an adjacent lignite station Deposition on the porcelain surfaces is favoured by hollows in the insulator which are protected from the wind and rain Several firms in Great Britain have installed fog and dirt chambers for the purpose of carrying out full voltage tests on these insulators, under the most severe conditions The solution favoured is that facilities should always be available for shutting down main transmission lines once a year for a thorough inspection and for the cleaning of the insulators This could be done at a period of light load

Vibration probably occurs on every transmission line in the world, but breakdowns due to it do not often occur In Mr Ryle's paper the swaying of the conductor as a whole, which is evident in a strong wind, was not discussed, nor was the 'dancing' of conductors which sometimes occurs when rapid changes in the load or the temperature occur He dealt with phenomena analogous to the humming of telephone and telegraph wires, the transverse vibration of aeroplane stay-wires which caused difficulty in the early days of flying, the regular swaying of tall factory chimneys across the wind, and the vibration of underwater towing cables The 'speed-wobble' on motor cycles, which is due to the front and rear halves of the front wheel tending to vibrate in opposite directions, is probably due to a similar cause

The cause of the vibration, which is, at least initially, in the plane perpendicular to the direction of the wind, is attributed to the instability of a type of air flow in the wake of a cylindrical body The eddies seem to set up alternating forces transverse to the wind, which tend to initiate and maintain vibration, especially when their period coincides with a natural period for transverse vibration Little is known at present of the various types of damping forces due to the air, elastic hysteresis in the wires and in the lattice towers Luckily, there is, in general, little probability of vibrations ever building up to large amplitudes, as a very slight change in the wind velocity alters the resonant harmonic Experience has shown that the vibrations increase the larger the conductor and the more tightly it is strung Wind velocities of between two and twenty miles per hour are the most effective in producing these vibrations Some guiding principles were given for the design of damping devices

Indian Lac Research.

THE Annual Report (to Mar 31, 1930) of the Indian Lac Association for Research gives evidence that the important work carried on at this Institute is making steady progress The Institute and its connecting buildings are almost completed, and the staff, which now numbers 24, has had added to it Dr R W Aldis, in charge of the physico-chemical section As the director and bio chemist, Mrs Dorothy Norris, states, "it will now be possible to examine closely each stage of the ordinary process of lac manufacture, with a view to checking waste and devising improvements"

For those interested in lac and its development and economics this report will well repay a study Briefly, the work at the Institute resolves itself into the following main features The formation of plantations of species of trees which are considered likely to produce the largest amount of lac The chief factors under study are (*a*) the sylviculture and requirements in soils, etc, of the different species and their success under varying climatic conditions, (*b*) the success attainable by employing manures in the plantations, (*c*) the chemical factors affecting or encouraging the growth of the trees on different soils, (*d*) the chemical differences in the sap of the twigs and their influence on the lac insect itself, (*e*) the seasonal variations in host plants of the lac insect, also under investigation in the laboratories of the bio-chemist and assistants, together with analysis work of lac obtained from different host plants

The other important section of the Institute is that on entomology, under Mr P M Glover, helped by a staff of nine Mr Glover divides the work of his branch into two groups—first, the bionomics of the lac insect, *Laccifer* (*Tachardia*) *lacca*, and secondly, the investigation of the insect enemies and friends of the lac insect, the latter including the enemies of lac host trees It is impossible to follow Mr Glover in the interesting account of the problems with which he is faced As an example it will be sufficient to state that one well known lepidopterous (Noctuidæ) pest, *Eublemma amabilis*, passes through six life cycles in a year and eight days, to indicate the complications which insect depredators add to the study of this valuable lac insect and its habits, and to the best methods of propagation and so forth The theory that ants preyed upon the lac insect and consequently diminished the crop is now officially disproved in the majority of cases investigated

That the work of the entomological branch, however, is of the greatest importance is supported by Mr Glover's statement on the damage done by pests "The annual stick lac production of India, including Burma and Assam, is in the neighbourhood of 1,700,000 of maunds [1 maund = 80 lb] valued at about Rs 6,80,00,000 The average percentage damage by insects to lac crops is 60 per cent; this means that the annual lac crop is roughly one-third of the hypothetical undamaged crop, giving an annual loss due to insect damage of Rs 13,60,00,000" It will be apparent that the study of the pests of lac and methods of combating them should well repay the sums expended on the research undertaken with this object in view

Fossil Wood from the Bituminous Sands of Alberta.

SINCE 1913 the Mines Branch of the Department of Mines of Canada has been carrying out, under the direction of Mr S C Ells, an extensive investigation of the bituminous sands (McMurray Tar Sands) of Northern Alberta In a long communication to the Editor, dated Jan 12, Mr Ells directs attention to the presence of fossil wood in these sands The discovery of fossil wood on the Ells River was first recorded by him in 1914, and later similar wood was obtained in shaft sinking operations near McMurray (*Report* 632, Mines Branch, Dept of Mines, Canada, p. 55, 1925) Many of these specimens and others found later were sent to Prof I W Bailey at Harvard University, who reported that one of the fossil woods belongs to some gymnosperm, not found growing in North America at the present day, which closely resembles in its wood structure *Sciadopitys*, the parasol pine of Japan Another he refers to the conifer *Keteleeria*, which is found in China and Formosa at the present day, while a third appears to belong to the type of wood called *Xenoxylon*, which has been found in Jurassic rocks These three types, which may be referred to the three form genera of fossil woods, *Phyllocladoxylon*, *Protopiceoxylon*, and *Xenoxylon*, from other records appear to have a stratigraphical range from the Jurassic onwards

The fossil wood, which is found in the McMurray Tar Sands in various sized fragments, up to trunks at least 40 ft in length, must have been transported, according to Mr Ells, by water, and afterwards embedded in sand The sands at a later date became saturated with asphaltic base petroleum, which impregnated and preserved the cellular structure of the wood

Other samples of these fossil woods were examined at the University of Alberta by Prof F J Lewis, who, in a letter to the Editor, dated Dec 23, 1930, states that some of the fragments of wood belong to the form genus *Cupressinoxylon*, a type of wood found in the cypress and several other conifers, living and extinct He also mentions that some of the wood is "Cordaitean in character with centripetal xylem" Without fuller details and photographs, it is impossible to express more than a guess as to the significance of these discoveries and identifications Wood of Cordaitean type with centripetal xylem is what one might have expected to find in Palæozoic rocks On the other hand, *Cupressinoxylon*, *Phyllocladoxylon*, *Protopiceoxylon*, and *Xenoxylon* would suggest a Mesozoic age for the beds This is consistent with the fact that the beds immediately below are found to contain a Jurassic flora It is to be noted that all the woods apparently belong to coniferous trees and there are no Angiosperms represented in the collection This negative evidence is in favour of a Jurassic or very early Cretaceous age, before the advent of the Angiosperms According to Mr Ells, the discovery in the beds of two shells, of a *Campeloma* and a Melanoid belonging to the genus *Pachymelania* on Hangingstone River gives an additional clue to the age, for *Campeloma* has hitherto not been found in beds older than the basal part of the Cretaceous in America

These various pieces of evidence, though not of much weight taken separately, point, on the whole, to an early Cretaceous age (or perhaps late Jurassic age) for the bituminous sands in which the fossil woods are found However, until these fossil woods have been identified specifically and compared carefully with similar woods of known geological age, they are of little value as stratigraphical indices One looks forward to the appearance of an adequately illustrated memoir on these interesting finds The specimen of "Cordaitean wood" may be of considerable botanical interest

Cancroid Crabs of America.

MISS MARY J RATHBUN has completed a third part of her series of handbooks on American crabs in a work entitled "The Cancroid Crabs of America of the Families Euryalidæ, Portunidæ, Atelecyclidæ, Cancridæ, and Xanthidæ" (Smithsonian Institution, United States National Museum, *Bulletin* 152, 1930) This monograph is on the same lines as those previously published, namely, "The Grapsoid Crabs of America" and "The Spider Crabs of America", and is equally valuable and well got up Not only does it enable one to identify the American crabs, but also it helps all carcinologists with its detailed and carefully prepared classification, synonymy, and tables of distribution

The Smithsonian Museum has recently been much enriched by large collections of crabs from South America obtained by Dr Waldo L Schmitt during his two series of explorations under the auspices of the Walter Rathbone Bacon scholarship These, together with several exchanges from various museums, make the South American collections very valuable Further investigations at the Tortugas and neighbourhood for the Carnegie Institution by Dr Schmitt and Mr Clarence R Shoemaker in co-operation with Dr William H Longley, in charge of the Laboratory, have contributed much that is of interest, and collections have been added from the University of Southern California and the California Academy of Sciences

A specially valuable find was a specimen of the extremely rare little crab *Metopocarcinus truncatus* Stimpson, of which the type is not extant, and this is the only one known to exist in any collection It is recorded from Cape St Lucas, Lower California, Mexico, and Valparaiso, Chile

It is with some reluctance that we call the common green crab *Carcinides* instead of *Carcinus*, but this alteration and the substitution of Euryalidæ for Corystidæ, to quote only one of many changes, are sound from the point of view of the International Rules of Nomenclature, as is also the restriction of the genus *Portunus* to those forms with nine lateral teeth each side of the carapace Mr Richard Palmer in his paper, "A Revision of the Genus *Portunus* (A Milne Edwards, Bell, etc)", in the *Journal of the Marine Biological Association*, N S, vol 14, No 4, 1927, discusses the subject with much fairness, and one cannot help hoping that the general opinion will be in favour of keeping our British forms with five teeth each side of the carapace in the genus *Portunus*

Nothing at all is said of the larval forms of any of the crabs, although now a good deal is known which is helpful in classification This is, of course, in keeping with the other volumes, but it is to be hoped that the time is not far distant when larval characters will be as important as any of those of the adult, and that the structure of larvæ and adults together will form the basis of all systematic work

The volume consists of 593 pages, containing many excellent figures, besides 229 beautiful photographic plates

The Atlantic Cod and its Races *

DR JOHS SCHMIDT'S happy intuition as to the choice of successful investigations is again exemplified by his latest memoir Here he has examined samples of cod from all over its north Atlantic region of distribution In each fish (about 20,000 in all) the numbers of vertebræ and the numbers of rays in the second dorsal fin have been counted The results are fully displayed in a series of tables and charts They are very remarkable and unexpected

The highest numbers of vertebrae (54 to 55 46) are found in the cod taken from the sea off the coasts of Newfoundland and Labrador, and the lowest numbers are those found in Irish Sea fish, we may summarise these results

Newfoundland Labrador	54 55 46 Vert	Temperature		0° 5°
Greenland, Iceland East Baltic	52 41 53 09	„	„	5° 10°
North from Scotland, North Sea	52 52 4	„	„	5° to > 10°
Rockall, West from Scotland Irish Sea	51 47 51 90	„		10° 15°

Thus there is an undoubted correlation between the values of a certain morphological character and the general sea temperatures throughout the whole region inhabited by the cod Dr Schmidt gives other examples of similar correlations (1) in respect of the number of rays in the second dorsal fin of the cod, (2) the numbers of vertebræ in both winter and summer spawning herrings, and (3) the numbers of vertebræ in the fish *Zoarces* The latter investigation was the subject of a previously published memoir and it is very interesting in a single fiord, for example, the numbers of vertebræ in the fish diminished regularly from the shore regions immediately outside the fiord to those at its inner extremity

Returning to the cod results, it is clear that there are local races with relatively restricted regions of distribution, and that there cannot be much intermigration between these localised regions This probably applies also to the distribution of the herring The conditions responsible for these segregations require investigation, and Dr Schmidt only touches this question Probably there is 'direct impression', or action, upon the developmental factors of the fish, during some 'critical period', by the external physical factors Certain experimental results actually suggest this, but, obviously, much more investigation is required Such a conclusion does not rule out the hypothesis that differences between the races are of a "hereditary, genotypical nature" It is, on the whole, improbable that the differences are due to selection of the variates Dr Schmidt's memoir is a model of clear and accurate exposition, and the results themselves are of unusual interest J J

* *Comptes-rendus des travaux du Laboratoire Carlsberg*, vol 18, No 6 'Racial Investigations, 10 The Atlantic Cod (*Gadus callarias* L) and Local Races of the same By Johs. Schmidt Pp 722 + 10 plates

University and Educational Intelligence.

CAMBRIDGE —The Appointments Committee of the Faculty of Biology "B" has reappointed Dr W E Dixon to be University lecturer in biochemistry, and has appointed Mr E T C Spooner, of Clare College, and Mr A A Miles, of King's College, to be University demonstrators in pathology

The following Grace has passed the Senate "That the Degree of Master of Arts, *honoris causa*, be conferred upon Ebenezer Everett, for many years assistant to Professor Sir J J Thomson at the Cavendish Laboratory"

THE Cecil Peace Prize of £100, which is offered yearly for an essay on some subject connected with the maintenance of international peace, to any undergraduate of any university or university college in Great Britain or Northern Ireland who has not attained the age of twenty five years, has been awarded to Mr G G Thomson (University of Edinburgh) for 1930, with Freda Marrison (University College of Swansea) as *proxime accessit*

THE annual meeting of the Association of Technical Institutions will be held in the Merchant Taylors' Hall, Threadneedle Street, London, E C 2, on Friday and Saturday, Feb 27 and 28 The proceedings will commence at 11 A M on Feb 27, when the chair will be taken by the president, the Right Hon Lord Eustace Percy, M P, who will introduce the president elect, Major General Sir Philip Nash Following this, an address will be given by Principal B Mouat Jones, on "Technical Education in Russia" Members and guests of the Association will afterwards be received by the Master and Wardens of the Merchant Taylors' Company, and luncheon will be served in the Company's Hall Friday afternoon and Saturday morning will be devoted to the reading of papers by Mr G H Gater, Chief Education Officer, London County Council, on "A Descriptive Account of Technical Education in London", Mr Comyns Carr, on "Industrial Administration", Principal J A Todd, of the City School of Commerce, Liverpool, on "National Certificates in Commerce", Mr J W Ramsbottom, Director, City of London College, on "Commercial Education in America"

THE report of a consultative committee, under the chairmanship of Sir W H Hadow, which was appointed by the Board of Education to inquire into the courses of study suitable for children (other than children in infants' departments) up to the age of eleven years, with special reference to the needs of children in rural areas, has just been published under the title of "The Primary School" (London H M Stationery Office, 1931 2*s* 6*d* net) The report may be regarded as the logical complement to the consultative committee's report on the "Education of the Adolescent" (1926) (Hadow Report), dealing as it does with the upper stage of primary education This important period in the development of children has, up to the present, been comparatively neglected by physiologists and psychologists Recognising this fact, the Consultative Committee obtained memoranda on the physical growth and mental development of children up to the age of eleven years from Prof H A Harris and Prof Cyril Burt The data contained in these memoranda (Appendices 2 and 3) and in other evidence obtained from various specialists are discussed in Chaps 2 and 3 Chap 4 deals with administrative problems, while Chap 5 discusses questions of the internal organisation of primary schools Chap 6, on the problem of retarded children at the primary stage of education, dealing especially with the chief causes of retardation, should be of considerable interest to teachers and administrators Chap 7 gives the views of the Committee on the general problem of the curriculum for children up to the age of eleven The sections on the "Study of Nature", and the memorandum on the anatomical and physiological characteristics and development of children between the ages of seven and eleven, by Prof H A Harris, and that on the mental characteristics of such children, by Prof. Cyril Burt, are of special interest

Societies and Academies.

LONDON

Royal Society, Feb 12 —**J Cohen, K Cooper**, and **P G Marshall** Some aliphatic and aromatic amino derivatives of α-quinoline methodide Many of the amino and acylamino compounds obtained by the condensation of derivatives of α-methyl quinoline with nitrosoarylamines possess active antiseptic and in some cases mild trypanocidal properties Sub stances obtained by attaching a basic aliphatic or aromatic side chain directly to the α carbon of the quinoline nucleus exhibited no marked antiseptic or trypanocidal character Diamino compounds of ali phatic and aromatic series with basic groups at both ends of the chain did not exhibit the expected anti malarial action —**C H Browning, J B Cohen, S Ellingworth**, and **R Gulbransen** The antiseptic and trypanoidal action of certain styryl and anil benzthiazole derivatives The anil benzthiazole de rivatives are relatively weakly antiseptic for *Staphylo coccus* and *B coli*, as compared with the quinoline analogues, which are highly active in this respect Several benzthiazole styryl compounds have pro duced cure of mice infected with *Trypanosoma brucei*, and the same relationships between chemical con stitution and trypanocidal action have been found to hold as in the styryl quinoline series Thus the maxi mum effect is produced when one nucleus contains a basic group and the other an acetylamino group The anil benzthiazole series, in general, possesses some trypanocidal action, but cure has only excep tionally been produced

Physical Society, Jan 16 —**L C Martin** The theory of the microscope The paper examines the diffraction effects produced by (*a*) two adjacent apertures, and (*b*) a series of apertures in an opaque screen situated in the focal plane of a lens system, when the illuminating system is projecting the ele mentary image of a point source of light into this object plane The diffraction effects and geometrical resolving power of the grating are shown to be inde pendent of the concentration of the light in the object plane, they depend rather on the number of aper tures free to transmit light The theory is then ex tended to the case where the illumination of the object is produced by a source of finite area —**J H Vincent** Further experiments on magnetostriction oscillators at radio frequencies The coil surrounding the bar can be in either branch of a simple tuned anode circuit When the bar coil is in the inductive branch the circuit may be operated as a series or parallel arrangement, in the latter case the direct plate current does not pass through the inductive branch of the fly-wheel circuit The variation in either the anode or the grid current can be used to indicate resonance Comparative experiments with corronil, nickel, and glowray suggest that glowray is the most suitable of these materials for high-frequency oscillators —**S Butterworth** and **F D Smith** The equivalent circuit of the magnetostriction oscillator The equivalent electric circuit is developed and ex pressions for its elements in terms of the fundamental constants of the material are given The circle diagram of impedances is deduced, and the modifying effects of eddy currents and hysteresis are investi gated Some simple geometrical relations between the vectors in the diagram are derived An experi mental investigation of the resonant radial vibrations of solid and laminated nickel rings verifies the theo retical deductions For nickel in the annealed state, $\lambda = 1\ 76 \times 10^4$ and $\kappa = 22\ 1 \times 10^4$ at a point on the curve corresponding to $H_0 = 14\ 5$ gauss

Geological Society, Jan 28 —**J. F N Green** The South West Highland sequence The present suc cession near Ballachulish can be paralleled in detail with Islay On attempting to apply the result to the neighbouring areas of Glencoe, Onich, and Cuil Bay, several amendments to current views are suggested The evidence supporting these amendments is given The three areas, Islay–Jura, Ballachulish–Appin, and Tayvallich–Loch Awe, are regarded as complex synclines of correlated rocks Between these synclines appear grey calcareous phyllites Between the phyllites and the flags or discontinuous quartzite occur shallow water beds, composed essentially of quartzitic conglomerate and calcareous sandstone, accompanied usually, but not always, by black slate

PARIS

Academy of Sciences, Dec 22 —**P Vincensini** A property relating to the deformation of surfaces —**Bertrand Gambier** Voss Guichard surfaces —**J Herbrand** A new demonstration and generalisation of a theorem of Minkowski —**Kourensky** The general isation of the Poisson Jacobi parentheses —**Henri Mineur** The K terms of the radial velocities When the mean radial velocity of the stars is developed in a series of spherical functions, the development con tains a constant, called the K term, which cannot be explained by the movement of the sun, or by the rotation of the whole of the stars The K terms for stars of known radial velocities have been calculated, classifying by types of spectra, by the distances from the sun, and by galactic latitudes —**André Lallemand** The photometric study of the solar corona for radia tions in the red and infra red The relation between the brightness (B) of an element of the corona and its distance from the sun (p) has been found to be

$$\log B = \alpha p + \log B_0$$

For a given wave length, α is constant and inde pendent of the region explored —**G C Moisil** The systems of Dirac equations of elliptical type —**Marcel Chopin** An apparatus for measuring the surface tensions of liquids The apparatus described and illustrated can be used for measuring surface tension in absolute values with quantities of liquid of the order of 0 15 c c —**J Basset** and **R Dupinay** The compressibility of nitrogen and of hydrogen at ultra pressures of 5000 atmospheres 1 c c of hydrogen at 1000 kgm /cm ^{2} becomes 0 456 c c at 5000 kgm /cm ^{2} 1 c c of nitrogen at 1000 kgm /cm ^{2} becomes 0 610 c c at 5000 kgm /cm ^{2} Apparatus is under construction for studying gases at pressures of 25,000 atmospheres —**P de la Gorce** The realisation of a resistance for measurements at very high voltages Description, with diagram, of an arrangement in use at the Labora toire central d'électricité for a steady load at 150 kilovolts —**P Girard** and **P Abadie** The hypothetical existence in water of resonators of Hertzian frequency Measurements of the dielectric constant of a solution of sodium silicate of concentration $1\ 5 \times 10^{-4}N$ for wave lengths between 50 18 cm and 60 28 cm have not proved the existence of dispersion bands, and the experiments of Weichmann and of Frankenberger cannot be confirmed —**Georges Fournier** The graphi cal calculation of the magnitudes connected with the electron in motion —**Z Zajac** The fluorescence of excited mercury atoms —**Louis Goldstein** The introduction of the exchange in the statistics of a gas of electrons —**André Guilbert** The thermal phenomena produced along hysteresis cycles —**Marcel Dufour** The representation of the astigmatic pencil and the auxiliary straight line of Mannheim —**J Dourgnon** and **G Waguet** Theorems relating to the brilliancy of secondary sources —**Constantin**

Salceanu The magnetic rotatory polarisation of organic substances liquefied by fusion Measurements are given of the magnetic rotation (field 36,000 gauss) of naphthalene and of β-methylnaphthalene for varying temperatures above the melting points of these substances the results are compared with those deduced from Mallemann's theory —**R de Mallemann and P Gabiano** The magnetic rotatory power of hydrocarbons in the gaseous state Special attention has been paid to the purification of the gases examined, fractional distillation being used where possible Data are given for the first six hydrocarbons of the paraffin series —**Charles Dufraisse and Léon Enderlin** *Contribution to the study of the reversible oxidisability of organic substances* the thermochemistry of the oxidation of rubrene The determination of the heats of combustion of rubrene and its oxides, proves that there is a loss of 23 calories when passing from rubrene to its dissociable oxide —**E H Buchner** The vapour pressure of jellies The author has been unable to confirm the results obtained by Paul Bary on the vapour pressure of jellies, and hence thinks it unnecessary to discuss the theoretical explanation given by the latter —**Paul Bary** The vapour pressure of jellies Reply to E H Buchner —**Marcel Godchot and Mlle G Cauquil** The dispersion of refraction of cyclanic hydrocarbons The refractive indices (n, n') for two wave lengths (λ, λ') have been determined for 23 hydrocarbons of the cyclo pentane, cyclo hexane, cyclo heptane, and cyclo octane series The specific dispersion $(n - n')/d$, where d is the density taken at the same temperature as the optical observations, shows certain regularities —**G Mahoux** The influence of high frequency oscillations on the treatment of metallurgical products When a steel containing nickel, chromium, and molybdenum was heated to 500° C for nine hours in a current of gaseous ammonia, its hardness and resilience are not appreciably changed Under similar conditions, but with the test piece submitted to high frequency oscillations, the hardness is increased to about three times the original value Other steels show similar changes —**Léon Guillet** Remarks on the preceding communication The importance of these researches is emphasised and the necessity for further work indicated —**Augustin Boutaric** A method of following the variation of the number of particles in the course of the evolution of a colloidal solution Application to blood serum The change in the number of particles in suspension can be followed by the comparison of measurements of viscosity and the optical density —**P Laffitte and M Patry** The detonation of explosive solids —**M Paić** The fusion diagram of the systems $HgBr_2 - HgSO_4$ and $HgCl_2 - HgSO_4$ —**Edouard Urbain** The acid magnesium potassium carbonates and magnesium ammonium carbonates —**A Travers and Franquin** The estimation of piperidine in a mixture of pyridine and its higher homologues —**J Wyart** The dehydration of heulandite studied by means of X rays —**L Royer** The possible orientation of cubical crystals deposited on a sheet of mica —**F Dupré la Tour** The polymorphism of the saturated dicarboxylic fatty acids as a function of the temperature —**R Weil** The peculiarities of amethysts and quartz rich in solid inclusions —**Albert Michel-Lévy** Crushed granulite and ante Stephanian mylonites at the north-east of the mountains of Espinouse —**Maurice Blumenthal** The transversal extension of the betic mass in the "Hoya de Malaga" —**Henri Termier** The existence of Caledonian folds in central Morocco —**J Devaux** The photometric study of the penetration of solar radiations in the interior of the Pyrenees glaciers—**J Thoulet** Aerial columns and submarine liquid columns —**R G Werner** The formation of lichens —**Maurice Hocquette** The evolution of the nucleus in the cells carrying bacteria of the nodules of *Ornithopus perpusillus* during the phenomena of infection and of intracellular digestion —**Marc Simonet** The cytological study of some hybrids of *Iris* —**Charles Pontillon** Variations in the unsaponifiable matter and lipoid phosphorus of *Sterigmatocystis nigra* as a function of the mineral composition of the culture fluid —**Paul Guérin** The development of the egg and polyembryony in *Erythronium dens canis* —**J R Denis and P Paris** The influence of light on the free plankton of fresh water —**M Bridel and C Charaux** Frangularoside, a new rhamnoside of recently dried alder buckthorn bark It is the custom to store this bark for a year before sale, and Schwabe has stated that franguloside does not exist in the fresh bark The authors confirm this view, since on applying the method which extracts 25 grams of franguloside from a kilogram of commercial bark, a different rhamnoside is obtained, to which the name frangularoside is given Hydrolysis of this new compound gives 41 per cent of rhamnose —**G Nicholas and Mlle Aggéry** New observations on *Phyllosticta Daphniphylli* and the increase of its action by bacteria —**Mme Lucie Randoin and Mlle Andrée Michaux** Variations in the proportion of chlorine in the blood serum and the variations of the chloride elimination in the course of acute experimental scurvy —**H Bierry** Protein, sugar and animal species —**L Bugnard and C Soula** *Cholesterolic regulation* —**C N Dawydoff** The post-embryonic development of the annamite *Cœloplana* The organisation of the larva —**E Roubaud** The existence of genetically distinct biological races in the common mosquito, *Culex pipiens* —**R Fosse, A Brunel, P de Graeve, P E Thomas, and J Sarazin** Application of the seed of *Soja hispida* deprived of uricase The qualitative and quantitative analysis of allantoin —**Jean Loiseleur** The state of the biochemical constituents, especially the proteins, in anhydrous solutions Proteins and other biochemical constituents are soluble in certain fatty acids, forming, in the absence of water, true solutions —**G Ramon** The production of the tetanus antitoxin —**Georges Fontès and Lucien Thivolle** Tryptophane and histidine deficiency regarded as contributing to Biermer's disease (progressive pernicious anæmia)

Melbourne

Royal Society of Victoria, Dec 11 —**J H Gatliff and C J Gabriel** Additions to, and alterations in, the Catalogue of Victorian Marine Mollusca Of the new records, ten are chitons, three bivalves, and twenty-two univalves, of which nine are included in the family *Turridæ* —**F Chapman and W J Parr** Notes on new and aberrant types of Foraminifera A new genus, *Heronallenia*, is proposed for some previously described species of *Discorbina* The genus is found fossil in the Oligocene of Muddy Creek, the Miocene of Batesford, and the Pliocene of England The recent specimens are recorded off the Falkland Islands, the Antarctic, New South Wales, and Japan The new genus, *Hofkerina*, has for genotype Howchin's *Pulvinulina semiornata*, and is a member of the family *Victoriellidæ* —**F Chapman** Occurrence of a fossil *Hydractinia* in Australia *Hydractinia thatcheri* is here newly described, from the Miocene of the Murray River Cliffs, South Australia It is quite distinct in specific structure from any previously described, and is the first occurrence of the genus in Australian rocks The perisarc is papillate and encrusts a once existing gasteropod shell —**W J Parr** Victorian and South Australian shallow water Foraminifera. One hundred and ninety four species and varieties are

recorded, including sixteen described as new Several usually warm-water species are found in Bass Strait, but not on the South Australian coast, while other species described from the Miocene of Victoria are now recognised for the first time as living in the same area

Diary of Societies.

FRIDAY, FEBRUARY 20.

ASSOCIATION OF ECONOMIC BIOLOGISTS (Annual General Meeting) (in Botany Department Lecture Room, Imperial College of Science and Technology), at 11 30 A.M.—*Discussion on Biological Races and their Significance in Evolution, to be opened by the President.* Other speakers — Dr W B Brierley (Fungi), Dr P Bruce White (Bacteria), Dr T Goodey (Nematodes), Dr W H Thorpe (Insects), Dr W B Turrill (Seed Bearing Plants).

GEOLOGICAL SOCIETY OF LONDON (Annual General Meeting), at 3.—Prof E J Garwood Presidential Address

LONDON SOCIETY (at Royal Society of Arts), at 5 —H. Robertson Modern Architectural Possibilities.

ROYAL SOCIETY OF MEDICINE (Balneology and Climatology Section), at 5 —Discussion on Research on Physiological Effects of Baths.

PHYSICAL SOCIETY (at Imperial College of Science and Technology), at 5.—G G Sherratt and J H Awbery On the Velocity of Sound Waves in a Tube —P S. H Henry The Tube Effect in Sound velocity Measurements —W A Wood Note on the Elimination of the β wave length from the Characteristic Radiation of Iron

BRITISH INSTITUTE OF RADIOLOGY (Medical Meeting) (at 32 Welbeck Street), at 5 —Dr H Cohen and Dr P H Whitaker Cinematograph of Ventriculography —Dr R E Roberts (*a*) Lympho-sarcoma involving the Stomach, (*b*) Carcinoma of Lung with Pathological Specimens —Dr J B Mather X Rays of a Case of Idiopathic Myositis Ossifican 1896 and 1930 —Dr H K Graham Hodgson Demonstration of the Technique of Method of Sinus Investigation —C T Holland Radiographs of Unique Conditions

SOCIETY OF CHEMICAL INDUSTRY (Liverpool Section) (Annual Meeting) (at Liverpool University), at 6 —L Wild Modern Developments in Printing

INSTITUTION OF MECHANICAL ENGINEERS (Annual General Meeting), at 6 —Capt A Swan, H Sutton, and W D Douglas An Investigation of Steels for Aircraft Engine Valve Springs —R. G C Batson and J Bradley The Fatigue Strength of Carbon and Alloy Steel Plates as Used for Laminated Springs

SOCIETY OF DYERS AND COLOURISTS (at Manchester Literary and Philosophical Society) at 7 —J S Wilson Solazol Dyestuffs

ROYAL PHOTOGRAPHIC SOCIETY OF GREAT BRITAIN (Pictorial Group—Informal Meeting), at 7 —Discussion on the Work of M Puyo

SOCIETY OF CHEMICAL INDUSTRY (Newcastle Section) (jointly with Northern Coke Oven Managers Association) (at Armstrong College Newcastle upon Tyne), at 7 30 —Dr S R Illingworth Some Aspects of the Carbonisation of Coal

ELECTRICAL DEVELOPMENT ASSOCIATION (at Royal Society of Arts), at 7 30 —T I Bernard Electrical Methods Ventilation and Air Conditioning

JUNIOR INSTITUTION OF ENGINEERS (at Royal United Services Institution) at 7 30 —A I Grant The Construction of the Variable Density Tunnel for the National Physical Laboratory at Teddington

SHIPLEY TEXTILE SOCIETY (at Shipley Technical School), at 7 30 —A B Shearer Rayon Its Uses in Woven Fabrics

INSTITUTION OF STRUCTURAL ENGINEERS (at Merchant Venturers Technical College Bristol) at 7 30 —R T Morgan Thames House

ROYAL SOCIETY OF MEDICINE (Obstetrics and Gynaecology Section), at 8. —*Dr A A Osman and Dr H G Close Observations on the Plasma Bicarbonate and the Value of Alkalies in the Treatment of some of the Renal Complications of Pregnancy*

ROYAL SOCIETY OF MEDICINE (Electro Therapeutics Section) at 8 30 —Discussion on the Future Policy of the Section

ROYAL INSTITUTION OF GREAT BRITAIN, at 9 —Prof J B S Haldane Prehistory in the Light of Genetics

GEOLOGISTS ASSOCIATION (North East Lancashire Group) (at Technical College Blackburn).—W L Turner With the Geologists Association in Czechoslovakia (Lecture)

ROCHDALE TEXTILE SOCIETY (at Technical Schools Rochdale) —Gregg Modern Weaving Methods

SATURDAY, FEBRUARY 21

NORTH OF ENGLAND INSTITUTE OF MINING AND MECHANICAL ENGINEERS (at Newcastle upon Tyne) at 2 30 —T V Simpson Old Mining Records and Plans —*Paper open for further discussion* —W H Connell Some Recent Improvements in Surveying Instruments

ROYAL INSTITUTION OF GREAT BRITAIN at 3 —J Stephens On the Reading and Speaking of Verse (2) Difficult Poets

MONDAY, FEBRUARY 23

INSTITUTE OF ACTUARIES at 5 —D Houseman Suggestions on the Legal Aspects of Life Office Practice

INSTITUTION OF MECHANICAL ENGINEERS (Graduates Section, London), at 6 45 —D G Sopwith Fatigue in Metals

INSTITUTION OF ELECTRICAL ENGINEERING (North Eastern Centre) (at Armstrong College, Newcastle upon Tyne) at 7 —E T Norris and F W Taylor High Voltage Testing Equipments —B L Goodlet, F S Edwards, and F R. Perry Dielectric Phenomena at High Voltages

ROYAL SOCIETY OF MEDICINE (Odontology Section), at 8 —A. Hopewell Smith (*a*) Evidence against the Theory of Metabolic Properties of Human Enamel (*b*) The Head of an Egyptian Mummy

ROYAL GEOGRAPHICAL SOCIETY, at 8 30 —P C Visser The Karakoram and Turkistan Expedition of 1929-30

CAMBRIDGE PHILOSOPHICAL SOCIETY (in Botany School Cambridge), at 8.45 —Prof E V Appleton Wireless Exploration of the Upper Atmosphere

INSTITUTION OF ELECTRICAL ENGINEERING (Western Centre) (at Cardiff). —Prof W Cramp The Birth of Electrical Engineering (Faraday Lecture).

TUESDAY, FEBRUARY 24

ROYAL SOCIETY OF ARTS (Dominions and Colonies Meeting), at 4 30 —A. Wigglesworth The Hard Fibre Industry, with special reference to the British Empire

IMPERIAL COLLEGE CHEMICAL SOCIETY (in Main Chemistry Lecture Theatre, Royal College of Science), at 5 10 —Prof G T Morgan The High Pressure Plant at the Chemical Research Laboratory, Teddington (Lecture).

ROYAL INSTITUTION OF GREAT BRITAIN, at 5 15 —Sir William Bragg Recent Experimental Physics (3) Adhesion (1).

INSTITUTION OF CIVIL ENGINEERS, at 6

INSTITUTION OF MUNICIPAL AND COUNTY ENGINEERS (North Western District) (in Geological Department, University, Manchester), at 6.30 —E. Morton The Properties, Selection, and Specification of Sandstones for Use as Kerbstones on Main Thoroughfares.

INSTITUTION OF ELECTRICAL ENGINEERS (North Midland Centre) (at Hotel Metropole, Leeds), at 7—E Fawssett and G E Moore Apparatus and Methods for Accurate Maintenance of Large A C Energy Meters.
INSTITUTION OF ELECTRICAL ENGINEERS (North Western Centre) (at Engineers Club, Manchester) at 7—E T Norris and F W Taylor High Voltage Testing Equipments.—B L Goodlet, F S Edwards, and F R Perry Dielectric Phenomena at High Voltages.
ROYAL PHOTOGRAPHIC SOCIETY OF GREAT BRITAIN (Scientific and Technical Group) at 7—E R Davies The Electrical Measurement of Reflection Densities, and a New Photoelectric Reflection Density Meter—M Games Demonstration of the Taxiphote
INSTITUTION OF ELECTRICAL ENGINEERS (Scottish Centre) (at 39 Elmbank Crescent Glasgow), at 7 30—Prof G W O Howe Wireless Telegraphy and the Upper Atmosphere
INSTITUTION OF ENGINEERS AND SHIPBUILDERS IN SCOTLAND (at 39 Elmbank Crescent Glasgow) at 7 30.—G J Lugt Supercharging with special reference to Werkspoor Engines
NELSON TEXTILE SOCIETY (at Nelson Technical College), at 7 30—J Yates Manufacturing Efficiency
QUEKETT MICROSCOPICAL CLUB (at 11 Chandos Street, W 1), at 7 30—Gossip Meeting
BRITISH KINEMATOGRAPH SOCIETY (at Film House, Wardour Street) at 7 45
ROYAL ANTHROPOLOGICAL INSTITUTE, at 8 30—Miss Winifred Lamb Excavations at Thermi in Lesbos
ROYAL AERONAUTICAL SOCIETY (Manchester Branch)—Alfred Herbert Ltd Machine Tools

WEDNESDAY, FEBRUARY 25

SOCIETY OF GLASS TECHNOLOGY (in Applied Science Department, University Sheffield) at 2—The Use of Ammonium Sulphate in Accelerating the Melting of Glass—M Parkin, Prof W E S Turner, and W J A Warren Part I Experimental Small Scale Meltings—The Research Staff of Imperial Chemical Industries, Ltd Part II Experimental Meltings in a Tank Furnace—Dr J T Howarth and Prof W E S Turner The Temperature of Incipient Glass Formation
BRITISH ASTRONOMICAL ASSOCIATION (at Sion College), at 5
GEOLOGICAL SOCIETY OF LONDON, at 5 30—Dr W J Arkell The Upper Great Oolite, Bradford Beds, and Forest Marble of South Oxfordshire, and the Succession of the Gastropod Faunas in the Great Oolite—Dr A Heard and J F Jones A New Plant (*Thallomia*), showing Structure from the Lower Downtonian Rocks of Llandovery, Carmarthenshire
NORTH EAST COAST INSTITUTION OF ENGINEERS AND SHIPBUILDERS (Teesside Branch—Graduate Section) (at Cleveland Scientific and Technical Institution Middlesbrough), at 7—H McIvor Some Aspects of Mechanical Design
INSTITUTE OF CHEMISTRY (Belfast Section) (at Royal Belfast Academical Institution), at 7 30—J A Matthew Effects of Air Humidity on Cellulose
ROYAL SOCIETY OF ARTS at 8—W G W Mitchell Developments in Television
C.B C SOCIETY FOR CONSTRUCTIVE BIRTH CONTROL AND RACIAL PROGRESS (at Essex Hall Strand), at 8 30—Dr Marie Stopes The Lambeth Resolutions and the Papal Encyclical—Some Contrasts and Comments
BRITISH PSYCHOLOGICAL SOCIETY (Medical Section) (at 1 Wimpole Street), at 8 30 Dr Adrian Stephen On Defining Psycho-analysis

THURSDAY, FEBRUARY 26

ROYAL SOCIETY at 4 30—J C Eccles and Sir Charles Sherrington Studies on the Flexor Reflex, I V—Prof A V Hill and J I Parkinson Heat and Osmotic Change in Muscular Contraction without Lactic Acid Formation
ROYAL COLLEGE OF PHYSICIANS OF LONDON at 5—Surgeon-Comdr S F Dudley *Some Lessons of the Distribution of Infectious Disease in the Royal Navy* (Milroy Lectures) (1).
ROYAL INSTITUTION OF GREAT BRITAIN, at 5 15—Prof J B S Haldane Respiration (2)
INSTITUTION OF MINING AND METALLURGY (at Geological Society) at 5 30
CHILD-STUDY SOCIETY (at Royal Sanitary Institute), at 6—Sir Philip Hartog English Composition for Children of Twelve and Upwards
INSTITUTION OF ELECTRICAL ENGINEERS at 6—Prof W Cramp The Birth of Electrical Engineering (Faraday Lecture).

Work of the Forestry Commission Progress and Promise

II

IN view of the fact that the first ten years period of the Forestry Commissioners' work was to expire at the end of March 1929 and that a new grant to continue the work would have to be obtained from Parliament, the Commissioners in 1927 discussed with the Government the question of a forest policy for Great Britain under the heads (1) general forest policy, (2) programme for the second decade (being an instalment of policy) which the country was in a position to undertake

Under the question of a general forest policy the Commissioners held that in order to ensure a supply of home grown timber (both softwood and hardwood) adequate for the normal well being of the nation and for safety in time of national emergency, it was necessary to proceed steadily with the afforestation of uncultivated land and the improvement of existing woodlands (almost totally neglected during the first decade) A census of existing woodlands was published by the Commissioners in 1924 An analysis of this most valuable and interesting report showed that the acreage of hardwoods in Great Britain was depreciating, and that the existing woods and the areas which had been felled were in a far from satisfactory position—that, in fact, there was little chance of the private proprietor being able to undertake the work

In the forecast of the present decade's work, it is stated " It had been hoped that the first decade would witness the planting up of arrears of fellings accumulated during the War, and the second (decade) improvement of existing woodlands and a large extension of the area under forest These expectations are very unlikely to be realised " This statement is a most surprising one to find in the report From 1922 onwards it must have been patent to the Commissioners, several of them important landowners, that the heavy taxation and death duties would make it impossible for the private owner to do much to assist the reafforestation of the areas felled during the War Further, the Commissioners presumably had at their disposition official statistics showing the position of the country generally *vis à vis* taxation, the breakup of estates, and so forth All that was needed was a broad forestry administrative experience to point the way to efficient handling of a difficult position

The Commission, however, was tied to a fixed annual coniferous planting programme This next

decade it is again tying itself down in a similar fashion There have already been many complaints throughout the country on the neglect to replant hardwood areas throughout the first decade, an insignificant 7000 acres being the total area dealt with by the Commissioners The latter comment upon the difficulty of dealing with the owners of such areas, touch upon the possibility of asking for powers for compulsory acquisition, etc But the proposed programme definitely shows preoccupation with the coniferous planting programme and a lukewarm attitude towards the existing forest or, better expressed, woodland areas, throughout the country—whether felled during the War, exploited since 1919, or being exploited (as are many oak woods) at the present time Owing to the neglect of the areas felled during the War, they have now been lying disforested for at least twelve years, the forest soil has deteriorated by that period of years, the surface is covered with a heavy weed growth, which will be expensive (and is proving so) to remove The Commission has offered grants to private proprietors to assist in the replanting of such areas, but admit the practical failure of this policy

The ten year forecast furnishes no evidence that the Commissioners have advanced any further towards a solution of this important matter It would appear that they intend to allow the bulk of these areas, possessing a true forest soil, to remain for twenty years unplanted, whilst they purchase elsewhere bare areas of necessarily poorer soil, to grow a coniferous crop, of problematical value at the end of a first rotation Surely the Commissioners realise that the discovery of a solution of this very urgent problem rests at their door At present they do not appear to have got further than the suggested possible course of asking Parliament for compulsory powers to acquire such areas It may be suggested that such a step would not unlikely prove widely unpopular and would do serious damage to the cause of forestry in Britain

That the value of the Commissioners' work since 1919 is recognised by Parliament is evidenced by the grants made for the next decade At the instance of the late Conservative administration, Parliament voted a sum of £5,500,000 into the Forestry Fund, commencing from April 1, 1929 This sum was increased by the succeeding Labour Government to £9,000,000 Forest receipts during the decade are estimated at £2,160,000—giving a total sum for expenditure during the period of £11,160,000.

For forestry operations the estimated cost for the decade is slightly more than £8,000,000 Provision is made for the acquisition of plantable land at a uniform rate of 60,000 acres a year The total planting programme is placed at 353,000 acres, made up of 330,000 acres of afforestation and 23,000 acres of replacements—that is, of replanting existing plantations! It is proposed to continue the system of planting grants, and it is anticipated that between £140,000 and £150,000 may be expended on this work during the decade On the subject of forest workers' holdings, it is laid down that 3000 will be established during the period, at an average cost of approximately £625 each Education and research are each to have allotted £100,000, and special services £20,000

The objects and aims of a forest policy in a country are not necessarily always involved in direct revenue returns in cash The indirect returns, in so far as they are advantageous to the community at large, may have a higher value In Britain it is this latter point of view which must govern the forestry question for some time to come So far as can be judged in these very difficult times, the grants made by Parliament may, through the indirect benefits accruing to the people, be fully justified, and the public may be obtaining a full return for the money expended Future generations will be able to give the true answer But it is believed that the advent of the Commissioners and of their work has already proved of benefit to the community on the countryside The second decade of their activities would be of even greater value to the country as a whole, if the Commissioners would tear up the Acland Report—of admitted value in its day, up to a certain point—and adopt a wider vision and broader principles of forest administration

Physiographic Evolution of Britain.

The Physiographical Evolution of Britain By Dr L J Wills Pp viii + 376 (London Edward Arnold and Co, 1929) 21*s* net

IT is one of the primary aims of stratigraphical geology to integrate into a picture or chart the results of the mapping of rocks or deposits and the palæontology of each noteworthy geological period From the early years of the last century, if no earlier, the pioneers such as Lyell and Trimmer had resorted to this method of portrayal, and the device has been employed by many, perhaps most, of their successors. Some have been content to represent an 'ideal landscape' or a restoration of the assumed distribution of land and water at some specific period of

an area of limited extent, while others, greatly daring, have transgressed narrower limits and attempted to depict regions of continental or even wider extent

In these exercises, more than in most speculations, an author is giving hostages which he may, to his sorrow after, have to redeem, at the same time, the discipline of a preliminary essay upon a map may, and doubtless often does, disclose incompatibility, quite as often as it opens wider vistas

The subject of the present work has been dealt with comprehensively by only two previous writers—Hull in 1883 and Jukes-Browne in successive editions in 1888, 1893, and 1911 These works still have a value, especially the last, for the stratigraphical data they furnish, allowance being made for corrections and results that have accrued from later researches, but Dr Wills's book approaches the subject with a fullness of knowledge to which the earlier writers could make no claim Though in the preface Dr Wills modestly defines his aim as "to fill a certain gap in student literature", there is, we venture to say, no geologist, adept or novice, who will fail to benefit by attentive reading, whether for its copious references to British and foreign literature or for the critical faculty which is brought to bear on the strong and weak points of attractive hypotheses

Part 1 is devoted to the physiographical principles upon which these reconstructions are based, and the subject is illustrated by a large number of well-chosen diagrams, most of which are original, either in their entirety or as the author's amplified interpretation of verbal descriptions of other writers (for example, Fig 9, c Ring-dykes and cone-sheets) A short discussion on the nature of the geological record completes Part 1, our author then plunges very literally *in medias res*—into, not the restoration of Pre-Cambrian physical geographies, but into the Post-Carboniferous systems! This is because "the newer rocks of the geological column on account of their greater simplicity are better fitted than the more ancient systems for a study of the physiographical phenomena of the past"

In these "newer rocks" the author includes the uppermost Coal Measures and Permian rocks, as they and the Trias, in his judgment, originated under more or less similar conditions on the surface of a new continent that he considers to have begun to emerge first in Coal Measure times The present reviewer is disposed to antedate the emergence of this land mass, in view of the many signs of continental conditions seen in the Old Red Sandstone and in the Lower Carboniferous beds throughout the greater part of the British area "It was during the latter part of the Carboniferous period that great earth-movements [the Hercynian] set in, which continued intermittently until its close and for long after"

At the close of the Cretaceous period, a critical condition had again come about which brought with it vast modifications of the European geography, by which the widely extended Chalk Sea was expelled from the greater part of northern Europe, at the same time that the Tethys maintained the character and to some extent the position of the Mediterranean

In our own region great events transpired, earth-movements began which were accompanied by volcanic activity affecting a tract extending from Cornwall to Greenland While these momentous changes were in progress in north-west Europe, others still more impressive were developing farther south The Tethys, which had long sustained the rôle of a great settling vat for the detritus of two continents, now began to yield in a reverse direction, and from a mainly synclinal arrangement became, under compressive stresses, mainly a geanticline nipped between the jaws of the two relatively rigid masses of Hercynian Europe and Africa The effects of this compression are seen in the overriding of the Alpine foreland by successive 'nappes' and the less pronounced reversals of the African slopes These features are illustrated by text-figures 72-84

The Cainozoic system in the Anglo-Parisian 'cuvette', a convenient term introduced by the author to signify "a basin in which sedimentation is going on", is discussed in Chap xvii, and the Quaternary Period under the headings "Glaciated Areas" and "Earth-movement and Climatic Changes in the British Extra-Glacial Area", in Chaps xviii and xix, is a valuable summary of the results of recent work in glacial geology, in which the author has played an important part, and the noteworthy effects of Pleistocene earth-movements in Britain and especially in Scandinavia

The author then reverts to the consideration of the Pre-Cambrian and Palæozoic systems which were held in abeyance until the more accessible record of the Post-Carboniferous series had furnished a readily intelligible illustration of the processes involved Parts 3-8 are therefore devoted to the review of the topics of the Pre-Cambrian

conditions, especially the physiographical processes indicated

"If we limit our studies to the era after a solid crust with continents and oceans had developed with an atmosphere and hydrosphere not greatly differing from those that have obtained in the Cambrian and more recent periods, it seems logical to assume that the processes of change were similar to those of later times, though they may have differed in degree and in the tempo at which they worked"

The Lower Palæozoic systems, embracing Cambrian, Ordovician, and Silurian, are treated as a study of a geosyncline developing in a marine area with insular or submarine volcanoes This geosyncline had for its foreland a continental mass, 'Atlantis', of which the portion now visible consists of the Outer Hebrides and the north-west Highlands, the foredeep comprised Scotland, the Lake District, and northern Ireland, a second deep, at times connected with the foredeep, extended from north Wales to south-east Ireland The sinking of the sea floor persisted in its main features throughout the Lower Palæozoic systems, and the distribution of the types of deposition is explained by reference to the regions of the sea floor

At or near the close of the Silurian period a new restlessness affected the British area, of which some indications had already appeared The geosyncline began to give way, just as in Tertiary times we have seen that of southern Europe did It was in fact nipped, as the type was later, between two massive jaws, of which that on the south-east is obscure The culmination of this movement is placed by the author in the time immediately preceding the Dittonian, or upper part of the Lower Old Red Sandstone, it affected not only the north-west and west of the British Isles but also extended in one direction through the length of Scandinavia, where its course is approximately north-east with overthrusting to the north west In its extension through Scotland and Ireland the alignment was changing to a more east to west direction in the south of Ireland, where it encounters the Atlantic Beyond the two apparent termini these Caledonides may with much probability be traced on the north in a majestic curve through Spitsbergen into northern Greenland In the opposite direction, in the Acadian chain of North America, comparable structures have long been known, the connexion being by an assumed syncline crossing the present floor of the North Atlantic, with a branch passing up Davis Strait and Baffin Bay

A transgressive series, marine in the south and continental in the north of Britain, brought in a new continental condition indicated by the Old Red Sandstone and Carboniferous series, to the description of which the author devotes some fifty pages The conditions of deposition of the Lower Carboniferous appear to have been more fully marine in the south and deltaic growths in the north, with occasional periods of balance between deposition and subsidence, leading to the formation of swampy flats upon which peat-beds to form coal seams were accumulated The clearer waters of the Anglo-Welsh area gave origin to great beds of Carboniferous limestone, the deposition of which was, however, controlled by faulting movements, of which the Craven faults marking off the 'Rigid Block' of Prof Marr are examples The researches of Garwood and his school have enabled the mapping of the components of the limestones and of the Yoredale facies to be traced over large areas through the British area

This phase was brought to a close by the invasion from the north of the great series of coarse grits of mainly deltaic origin with intercalations of marine shales characterised by a succession of goniatites, forms by the aid of which the baffling complication of sandstone beds has been unravelled A very full discussion of the conditions attending the deposition of the Coal Measures, perhaps the most complete 'restoration' which is possible for any British formation, and the formation and constitution of coal seams brings this section to a close

A concluding chapter is devoted to the description of the succession of volcanic rocks in the British series

It remains to say that the book is very fully indexed P F K

The Problem of Chemical Affinity

Le problème de l'affinité chimique et l'atomistique étude du rapprochement actuel de la physique et de la chimie Par Prof Charles Brunold Pp v + 118 (Paris Masson et Cie, 1930) 20 francs

THE author of this very interesting essay has dealt with the theme of chemical affinity in its relation to physical theories from the early period to the present day His treatment is historical and critical, and the main conclusion which he reaches is that the problems of chemical combination grouped together under the concept

'affinity' have always proved, and are for some time likely to prove, much too complex and specific to allow of any explanation by prevailing physical theory which will prove at all satisfying to the chemist He begins his historical account by the statement that "the notion of affinity was introduced into science in 1733 by Boerhaave", whereas it is well known that the name was used by Albertus Magnus, and that very detailed investigations on elective affinity were published by Mayow in 1674, based on earlier quite definite and clearly expressed opinions of Boyle These ideas, carried further by Stahl (whose results seem to be incorporated, without acknowledgment, by Newton in his "Opticks"), were summarised in the Affinity Tables of Bergman The first attempt to explain the results on the prevailing physical theory made use of mechanical conceptions, since mechanics was then the senior branch of theoretical physics Newtonian attractions were introduced, and when the researches of Berthollet had removed the foundation of Bergman's theory, their author could still make appeal to the mechanical attractions between the particles to account for the action of mass

With Davy and Berzelius another epoch began The study of electricity had become of predominating interest in physics, and the electrochemical theory sought to subordinate all chemical theories to the laws of electrostatics This view, in turn, soon proved insufficient, and the study of carbon compounds and substitution turned the thoughts of chemists away from the views of Berzelius The latter, however, had much in them which has reappeared in modern theory, especially in the views of Kossel, and as M Brunold says, the explanations which may serve for the compounds of one single element, carbon, need not necessarily apply to the other ninety-one It has gradually become clear that there are, in fact, two different types of valency at least, 'polar' in ionic salts and 'non-polar' in compounds such as those of carbon The ordinary valency formulæ, which may express well enough the reactions of carbon compounds, fail completely in the chemistry of other elements The theory of Werner has filled an important place in this field, and it would have been desirable for M Brunold to have devoted a little more space to its explanation With the advent of the theory of energy, a relation between affinity and heat of reaction was introduced, but this in turn proved abortive

After the new advances in physics leading to the isolation of the electron and the study of the structure of the atom, another attempt to explain the phenomena of chemical combination could be made The earlier atom models are considered one by one, and the reasons for their abandonment (after they had promised to provide explanations of valency) are explained In the closing pages of the book it is made clear that the latest atom models are in turn fading from the screen, and that "the mechanics of Bohr seems to-day out-of date" In this section, the important part played by the Periodic Table, an achievement of pure chemistry, is properly emphasised "Every time that the theories or methods of physics have, in the study of chemical problems, attacked a case of some slight complexity, they have been compelled to make an appeal to the results of chemistry, that is to say, to renounce at least provisionally a development according to their own proper means"

It will be seen that the opinions of the author, all of which are most carefully reinforced by relevant chemical facts, are not without a certain vigour, and the book is one which both chemists and physicists can read with interest and profit The molecule with which the chemist operates is to a large extent static, and whatever relation it may have to prevailing physical theory, the 'octet' is something which, according to M Brunold, 'works'

Philistine Cities

(1) *Gerar* By Sir Flinders Petrie Pp vii + 34 + 72 plates 50*s*

(2) *Beth-Pelet I (Tell Fara)* By Sir Flinders Petrie, with a Chapter by Olga Tufnell Pp vii + 26 + 72 plates 50*s*

(3) *Corpus of Dated Palestinian Pottery* By J Garrow Duncan Including Pottery of Gerar and Beth Pelet dated and arranged by Sir Flinders Petrie, and Beads of Beth-Pelet dated and arranged by J L Starkey Pp 21 + 83 plates 30*s*

(London British School of Archæology in Egypt, Bernard Quaritch, Ltd, 1928–1930)

THE British School of Archæology in Egypt has widened the scope of its activities, and since 1926 has conducted excavations in the coast plain of south Palestine For this change there was the excellent reason that the only period of Egyptian history of which even the outlines are obscure is that of the Hyksos conquest, and for this it was in this quarter, whence those conquerors apparently came, that clues were most likely to be found

(1) In 1926 and 1927 the selected site was Tell

Gemmeh, identified with the Biblical Gerar, eight miles south of Gaza and from the coast, a natural hill of fifty feet, covered by another fifty feet of debris, scarped by the Wady Ghuzzeh and deeply eroded by wind and rain, so that only a small area of its original platform-top remains Six successive periods of building were uncovered, within a depth of thirty feet, each ignoring its predecessor, so that there was good evidence for distinguishing the contents of each They were assignable, respectively, the latest to the Persian conquerors in the sixth century B C , the earliest to the Egyptian protectorate of Thothmes III in the fifteenth Between these there were reoccupations by Rameses III about 1194 B C , by Shishak about 930 B C , by the Jewish Amaziah about 810 B C , and by Psammetichus I about 660 B C

Among architectural remains, the great military granaries are notable among the small objects, an interesting series of safety pins, of local workmanship, and surprisingly early date, according to the excavators , the copious strings of amulets and beads, of the centuries from 1200 to 950 B C , the evidence not only for iron smelting but also for the tempering of swords, about 870 B C , and the rudely sketched linear designs on limestone incense-burners resembling those of iron age Cyprus The pottery, especially in the 'Philistine' period, is influenced, as at Lachish and Askalon, by Minoan pot-painting from oversea The numerous weights give a clue to successive commercial systems which have prevailed along the great corridor between Asia and Egypt, in which Gerar lay

(2) In 1928 work was begun at Tell Fara, a large site, rather farther inland, and deeply eroded by the Wady Ghuzzeh so that its structure was revealed, with nearly fifty feet of ruins on a natural hill a hundred feet high Practical difficulties were greater here than at Gerar, the nearest water, for example, being eleven miles off The position and contents of this site identify it, as its name also suggests, with Beth Pelet, the home of the Pelethites, King David's royal bodyguard Besides the contents of the fort and its houses, the cemeteries yielded instructive material The Hyksos period, with characteristic un-Egyptian pottery, and scarabs imitated from a series of Egyptian models, runs from the days of the XIIth Dynasty to the XVth, which represents the Hyksos conquerors of Egypt, as known from graves at Yehudiyeh and it is claimed that the sequence of scarab designs at Tell Fara shows that the XIIIth and the XVIth Dynasties were parallel, and began together at the close of the XIIth.

The Egyptian protectorate of the XVIII-XIXth Dynasties is a period of conflicting influences Egyptian from the south, and Minoan from oversea Debased Minoan decorations are here dated surprisingly early, and oddly identified The scarabs seem to be still the basis of chronological sequence A steel dagger (Pl xxi 90) about 1370 B C is noteworthy both for form and for material Tutankhamen's dagger is of the same generation Flange hilted daggers of bronze are also early of their kind , and there are some interesting forms among the ear rings A terra-cotta horseman (TM 379) is oddly described as "Scythian" though dated "to the age of David and Solomon"

A notable group of tombs is described as "Solomonic" They are stone-lined and roofed with stone-slabs, and contained ornaments of gold, with occasional electrum and silver and fine cornelian beads The ivory gaming board, 188, is described as "unique" on p 12, but as "a well-known form" on p 109 Among the later tombs, the Egyptian lotus ornament on a vase (17 K7 in text, cf 17 P5 in Pl xxxix) is notable, if it be so early as is said , and the calendar reckoner (Pl xl 481) very curious On the small face-amulets (xl 493-5) the feather head-dress of the 'sea-raiders' of Ramessid times reappears Far the finest art works from this site are the silver bowl and bronze ladles, and the jointed bedstead of iron, bronze, and wood, from a fine tomb of about 850 B C

The fort itself shows the same characteristic glacis defences as Hyksos sites at Yehudiyeh and Heliopolis Its inner arrangements have naturally been much remodelled under Egyptian, Philistine, and Israelite rule , and the site was heavily refortified during Shishak's occupation of Palestine in the tenth century

(3) Mr J Garrow Duncan's "Corpus of Dated Palestinian Pottery" includes the new material from Gerar and Beth-Pelet, and also from the American excavations at Bethshan. The arrangement is by shapes, and consequently fabrics are often mixed, as well as periods and sites , but for ready reference the shapes are most easily recognised , and a convenient notation gives a clue to date and provenance Decorative designs are also analysed into their component motives, again irrespective of style or fabric , which is much less convenient or instructive At the end is a similarly constructed key to Palestinian beads There are some useful notes on the general discrepancies in dating among earlier excavators in Palestine, and on the uselessness of certain well-known pieces of work, through neglect of obvious precautions.

Our Bookshelf.

Leçons de géométrie projective Par Prof Federigo Enriques Traduit de la quatrième édition italienne par Prof P Labérenne Pp iv + 430 (Paris · Gauthier-Villars et Cie, 1930) 60 francs

THE present French translation from the fourth edition of these lessons on projective geometry by the eminent Italian mathematician-philosopher to a certain extent meets a long-felt want Perhaps the most striking feature of the book is the remarkably clear and consistent way in which the subject is developed from its logical foundations solely by means of graphical methods, based upon five purely geometrical postulates together with a sixth which is the geometrical equivalent of Dedekind's continuity theorem Although so much stress is laid upon projective constructions, the relations between projective and metrical geometry are expounded in the text whenever occasion arises, whilst the connexions with group theory and algebraic geometry are touched upon in several appendices

As regards the detailed arrangement of the book, it is sufficient to state that the first five chapters deal with definitions, fundamental propositions and preliminary theorems, the law of duality, the postulate of continuity, and Staudt's theorem Then follow chapters on projectivities and involutions between forms of the first and second ranks, with applications to conics, their projective and focal properties, and to cones, ruled quadrics, and twisted cubics A chapter on projectivities between forms of the third rank completes the work The perusal of this book is sure to afford great pleasure to all interested in the development of projective geometry

Testing Radio Sets By J H Reyner Pp vii + 178 + 8 plates (London Chapman and Hall Ltd , 1930) 10s 6d net

THIS book gives a series of suggestions for the tracing of faults in the simpler types of receiving apparatus It is not likely to be of assistance to qualified radio engineers , but, as there are few books on the subject, it will be useful to amateurs with a limited amount of technical knowledge The author's discussion of the effects produced in a high frequency choke coil is correct, provided that it is not in parallel or virtually in parallel with other components of the receiver. The conclusion he draws (p 59), that it acts like a small capacitance which has the property of allowing direct current to pass through it, is too vague The advisability of discharging the condensers in an eliminator or mains-driven receiver is pointed out The way he suggests, however, of placing the metal part of a screwdriver across the terminals of the reservoir condenser, is open to criticism, for such violent discharges have been known to damage the condenser. It would be better to discharge it through a resistance

The part of the book dealing with 'laboratory testing' seems to be a brief outline of the measurements that can be made in the author's own laboratory In places it would be well if the author had been more explicit On p 23, for example, we read, "we will assume that this circuit functions, but in a poor manner" There are many different 'poor manners' in which a circuit can function The chapter on American test data will be useful

Growing Tree and Small Fruits By H B Knapp and E C Auchter (The Wiley Farm Series) Pp xiii + 510 (New York John Wiley and Sons, Inc , London Chapman and Hall, Ltd , 1929) 15s net

THE needs of practical fruit-growers and students are here specially catered for by providing them with a text book which can also be used as a reference volume for points of detail To this end, an attempt has been made to render the various sections of the book complete and independent, in order that information unnecessary for the individual may be passed over without fear of losing other points germane to the question in hand Each of the main fruits is dealt with separately, from harvest to harvest, marketing operations being included , and in addition special chapters are devoted to wider problems of more general application, including, amongst others, orchard establishment, pruning, propagation, thinning fruit, and the control of diseases and pests Here again, where necessary, the application of the problem to particular fruits is indicated individually and adequately indexed The scientific names of some species of the common fruits are appended , and hints for practical work, given at the end of each chapter, increase the usefulness of the volume for students' class work

The Journal of the Institute of Metals Edited by G Shaw Scott Vol 43 Pp xii + 838 + 40 plates (London Institute of Metals, 1930) 31s 6d net

STUDIES of the influence of gases on cast metals occupy an important place in this volume Both hydrogen and sulphur dioxide cause unsoundness in copper and bronze, and removal of them by means of nitrogen or some other insoluble gas, or by melting under reduced pressure, has been found to improve the quality of the ingots or castings The four papers on this subject all owe their origin to the Non-Ferrous Metals Research Association, whilst the same body is responsible for the work by R Genders on the increased resistance to corrosion produced by the addition of small quantities of aluminium to brass, this being one of a number of instances now known of the protection of an alloy by an external film consisting mainly of aluminium oxide A communication by C F Elam is interesting as recording the progress of solid diffusion of zinc through brass by the application of X-ray methods A lengthy paper by T A Rickard on the early use of the metals led to a discussion in which archæologists as well as metallurgists took part The scope of the Institute of Metals is wide, and its journal is an invaluable source of information concerning the progress of metallurgy

The Meaning of Existence.

PROF. MUIRHEAD'S illuminating letter in NATURE of Feb. 7, p. 197, raises innumerable questions which I am not qualified to discuss with him, but I should like to add a comment on the narrower scientific aspect of the problem.

Here are two quotations, forty years apart, from eminent men of science:

(1) Lord Kelvin in 1889:—"[The ether] is the only substance we are confident of in dynamics. One thing we are sure of, and that is the reality and substantiality of the luminiferous ether."

(2) Sir Arthur Eddington in 1929:—"Among leading scientists of to-day, I think about half assert that the ether exists, and the other half deny its existence; but as a matter of fact both parties mean exactly the same thing and are divided only by words."

We are in the paradoxical position that two scientific workers of to-day who say "Yes" and "No" both mean precisely the same thing, while two scientific workers forty years apart, who both say "Yes", mean diametrically opposite things. The key to the paradox is, I think, to be found in Prof. Muirhead's words: "before there can be any talk of existence you must define the world within which it is affirmed—what the logicians call 'the universe of discourse'."

The physicist of forty years ago did not suspect the need for any such definition. Surrounding and conditioning our world of consciousness, he saw a vast independent universe of concrete machinery, which he unthinkingly and unconsciously accepted as his 'universe of discourse'. On the other hand, the scientific worker of to-day finds his 'universe of discourse' in the phenomenal universe as apprehended by his brain. The crux of the matter seems to me to be that this does not—like the old ocean of machinery—provide a single, clearly defined 'universe of discourse'. It rather gives us a collection of universes of discourse, some greatly overlapping but some almost independent, some objective but some largely subjective.

First there is the universe of the astronomical observatory and the physical laboratory, which is "continuous with the world of the felt, waking body", experience showing that this is identical for all of us, at any rate outside lunatic asylums. I think science now compels us to give an unqualified denial to the existence of an ether in this universe of discourse.

Then there is the mathematical universe of discourse, which deals only with such phenomena as can be reduced to 'pointer readings'. Those who want an ether in this universe may have it, just as they may have Cartesian or polar co-ordinates if they want them; but it will be a mathematical ether, not 'continuous with the world of the felt, waking body'.

Finally, there is the universe of discourse provided by that world which, in Prof. Muirhead's words, "resolution into mathematical symbols or 'pointer-readings' fails to make intelligible", including—if one must use the word—the world of 'values'. Although I am in almost complete agreement with Prof. Muirhead, I differ from him in thinking that an ether can have any existence in this world, or even any meaning, mainly, I suppose, because 'values' do not enter into clearly defined relations with time and space. In brief, I would contend that in the physical world an ether is non-existent; in the mathematical world it comes into being at the beck and call of the mathematician; in the world of 'values' it is meaningless.

J. H. JEANS.

Validity of the Genus *Sinanthropus*.

PROF. MARCELLIN BOULE, Director of the Museum National d'Histoire Naturelle in Paris, has written to me with reference to my Henderson Lecture, "The Significance of the Peking Man", extracts from which appeared in NATURE of Feb. 7 (p. 202), to direct my attention to the fact that long before Dr. Weinert expressed doubt as to whether the Peking man should be excluded from the genus *Pithecanthropus* he had made the same protest. To quote his own words: "Je crois être le premier à avoir rapproché intimement le *Sinanthropus* du *Pithécanthrope*. Voyez *L'Anthropologie*, t. 39 (1929), pp. 455-460."

In my Edinburgh lecture I purposely refrained from mentioning Prof. Boule's name, because his opinion was expressed before the fuller information was available, which seems to me to be fatal to his view. Dr. Weinert's book was written, however, after this evidence was issued. Hence it was not unfair to quote him as the supporter of an opinion which I think is mistaken.

The question of priority is not a matter of any particular consequence. As a matter of fact, at a meeting of a students' society in this College (the University College and Hospital Anthropological Society), before either Prof. Boule or Dr. Weinert raised this question, Dr. H. S. Harrison, of the Horniman Museum, started a discussion by suggesting that the fossil from China was a representative of the genus *Pithecanthropus*.

I should like to point out that in his preliminary announcement of the discovery of the skull (on Dec. 2, 1929) Prof. Davidson Black directed attention to its resemblance to the calvaria of *Pithecanthropus* but gave cogent reasons for according it generic distinction. The profound contrast of a fossilised human tooth from China to those of *Pithecanthropus* was pointed out so long ago as 1903 by Prof. Max Schlosser (*Abhandl. d. k. Bayerisch. Akademie Wissensch.*, Math. Phys. Klasse, Bd. 22, p. 20), and in his great monograph (*Palæontologia Sinica*, 1927) on the tooth which served as the type of the genus *Sinanthropus*, Prof. Davidson Black still further emphasised the contrast and justified his action in creating the genus, the validity of which is admitted by every palæontologist who has seen the actual specimens. As I have emphasised in my Henderson Lecture, the form of the brain case, the morphology of the individual bones, and even the architecture of the diploe, all corroborate the inferences drawn from the teeth that *Sinanthropus* is a distinct genus. Although the fossil from China definitely approaches more nearly to *Pithecanthropus* than to any other genus, the monograph which Prof. Davidson Black has written for immediate publication in *Palæontologia Sinica* (ser. D, vol. 7, fasc. 2) provides the full evidence, comparative data, and the statistical justification for its generic independence.

While the question of determining what criteria are necessary to justify the creation of a separate genus is one that does not admit of an exact answer, I do not think that anyone who has compared, as I have recently done, the actual Chinese fossils with those of other men and apes and the casts of fossil human skulls, would fail to realise that the inclusion

of the Peking man in the genus *Pithecanthropus* would introduce an undesirable element of confusion into this difficult field of interpretation

Raman Lines in X-Ray Spectra

A VERY interesting and significant phenomenon has been described by Ray [1] and by Majumdar,[2] in which it is shown that a quantum of the radiation energy, say of the wave length comprising the copper K_α lines, may, on passing through carbon or aluminium, be diminished by an amount sufficient for the ejection of a K electron from a carbon or an aluminium atom, and then pass on in the same or very nearly the same direction with a reduced energy $h\nu'$, and consequently a greater wave length

$$\nu' = \nu_{a1} - \nu_k,$$

where ν_{a1} is the frequency of the copper K_{a1} line, and $h\nu_k$ is the energy required to remove a K electron from the carbon atom

In the communications mentioned above, photographs are shown in which lines may very plainly be seen corresponding to this part absorption in carbon, nitrogen, and oxygen It was stated that carbon in the form of soot was used, but nothing was said as to how thick the absorbing layer was, nor regarding the manner of employing nitrogen and oxygen Since, in every case reported, a line due to at least one of these gases appeared along with the line due to carbon, it is evident that the three substances were all used at the same time In discussing the work of Ray, Bhargava [3] says the X rays passed through air, and Ray, in his later paper,[4] makes no comment on this point, but mentions that a Siegbahn vacuum spectrograph was used

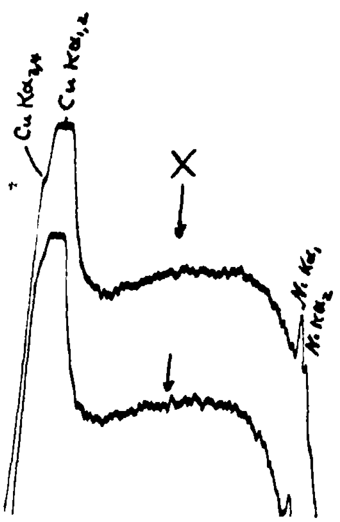

FIG 1 —Photometric curves of spectrum taken through a carbon absorbing screen

The question of such absorption is so important that I have also attempted to obtain these lines photographically, but have been quite unable to find them In my work a copper target was used, first with a tungsten filament, and later with one of nichrome, so that the layer of tungsten, which sputters on the target from a tungsten filament, might not be present, thus giving greater intensity to the copper radiation, and also avoiding the stronger continuous spectrum from tungsten

The carbon, first in the form of graphite, and later in the form of so-called amorphous carbon, was placed in the X ray tube immediately before the slit Afterward it was also used just against the slit on the other side, facing the crystal The optimum thickness of the carbon screen for manifesting the effect sought should be $\frac{1}{\mu}$, where μ is the linear coefficient of absorption of the given wave length for carbon Screens were used of varying thickness, some thicker than the above value, and some thinner

The spectrograph had a radius of about 14 cm It was not evacuated The calcite crystal was rotated uniformly over nearly one degree, by means of clockwork In some trials it was also turned by hand about every ten minutes, and in other cases it was left stationary during the entire exposure The time of exposure varied from five to nineteen hours The tube current was from 10 to 25 milliamperes, and the voltage, while not accurately measured, was perhaps from 15 kilovolts for some exposures to 35 for others

In cases where the crystal was allowed to stand, or was moved irregularly, certain lines, often quite sharp, appear, especially near the limit of the continuous radiation If the crystal is moved, these lines also move and appear in another place It is a common experience that such lines may be found with almost any crystal if it is not properly rotated In my best photographs, with uniform rotation of the crystal, it is quite impossible to see any line in the place required for the partial absorption in carbon, and as found by Ray Unfortunately, he does not state how the crystal was rotated in his experiments

Ray has estimated the relative intensity of these Raman lines to be about $\frac{1}{100}$ or $\frac{1}{500}$ that of the copper K_α lines Now Richtmyer and Taylor [5] give the intensity of the satellites $K_{a3,4}$ of copper as about $\frac{1}{100}$ the intensity of copper K_{a1} On my plates the line copper $K_{a3,4}$ is strong, hence I conclude that the exposures are sufficiently long to produce the lines sought, if they were present in anywhere near the above intensity

Fig 1 shows a photometer record of one of the plates obtained The two curves were taken at different levels across the spectrum to show that the irregularities are due to the grain in the plate X marks the point in the spectrum at which the displaced line due to carbon should appear The $K_{a3,4}$ line can be seen plainly

Modification of Quanta by Photo-Ionisation

IN continuation of our previous communication of experiments on the phenomenon described by Dr B B Ray,* we wish to report that we allowed silver $K\alpha$ radiation to pass through nickel foil 0 06 mm in thickness, and photographed the spectrum of the emergent ray We found, after an exposure of 150 mA hours, a modified band with a sharp edge at ν/R = 1019 7, fading towards the long wave length side, but with no trace of blackening on the short wave length side The difference between ν/R of silver $K\alpha_1$ and that of the sharp edge obtained is ν/R – 612 9, while, according to Siegbahn, ν_k/R of nickel (K absorption edge of nickel) is 612 The experiment, therefore, clearly supports the view that the quantum on its passage through the atom may impart to the electron in the K shell all energies from $h\nu_k$ to $h\nu_0$ and become modified to quanta of any frequency less than $\nu_0 - \nu_k$

Raman Spectra of Organic Sulphides

IT is more or less generally accepted that the various Raman frequencies of a molecule correspond to the oscillations of its component parts with respect to one another, each frequency being associated with one particular mode of oscillation This conception of the origin of the frequencies is very fruitful in correlating the Raman spectra of molecules with their structure One particular aspect of the application of this idea has attracted considerable attention during recent years, namely, the assigning of certain frequencies to each type of chemical bond and tracing their variation from compound to compound We have made a detailed study of the Raman spectra of a number of organic sulphides and we give below the results obtained in two typical cases, ethyl sulphide and allyl sulphide, one representing the saturated and the other the unsaturated compound

The Raman spectrum of ethyl sulphide is very simple, while that of allyl sulphide is rich in lines and also presents a continuous background A comparison of the scattered spectrum of ethyl sulphide with that of ethyl ether shows a general agreement so far as the long shifts are concerned The effect of the substitution of the heavier sulphur atom in the place of oxygen is to diminish the frequency shift, the changes in the shift getting smaller as the value of the shift increases

	Wave numbers per cm
Ethyl Sulphide $(C_2H_5)_2S$	652, 1061, 1282, 1439, and 2923
Allyl Sulphide $(C_3H_5)_2S$	410, 588, 741, 917, 1011, 1101, 1210, 1291, 1312, 1420 1534, 1636, 3007, and 3088

Thus, corresponding to the sulphide shifts 1061, 1439, and 2923, we have the other shifts 1082, 1457, and 2936

The Raman spectrum of the sulphide resembles that of the corresponding alcohol in the region of the longer frequency shifts, while conspicuous changes are observable in the region of the shorter shifts The frequency 652 in ethyl sulphide, which is presumably due to the C–S bond, is also the prominent frequency in carbon disulphide, the nature of the bond apparently having no effect on the oscillation frequency This frequency is absent in allyl sulphide Similarly, the prominent frequency 741 in allyl sulphide (which is also present in allyl thiocyanide) is absent in ethyl sulphide It seems that the frequency 741 is characteristic of the unsaturated sulphides, and the frequency 652 of the saturated sulphides

The General Factor in Spearman's Theory of Intelligence

I HAVE recently undertaken an investigation of the theory of 'factors' from a mathematical point of view This work is now complete and I hope to publish it shortly in full The conclusions in brief are that, with certain reservations, the theorems relied on by psychologists are correct. They are, further, independent of the theory of probability that is to say, no questions of distribution arise until we come to applications

It is surprising that this comparatively simple work has not been done before The reason seems to be that it has always been approached from the probability point of view, whereby difficult but irrelevant considerations have been introduced. It may, however, be noted that Yule in his classical paper on partial correlation (*Proc Roy Soc*, 1907) proved his results independently of distribution, and that Spearman (*Proc Roy Soc*, 1922) stated that the theorem proved by Garnett for error distributions (*Proc Roy. Soc*, 1919) had a similar generality This is the subject of Prof Piaggio's letter in NATURE of Jan 10 Another reason why mathematicians have as a rule failed to interest themselves in the theory lies in the special meanings assigned to common mathematical terms by statisticians and psychologists independent for orthogonal, factor for component, array for section, etc, and the extension of the term 'error' to cover all components not under consideration

The subject matter of statistical science is sets of measures of variates, that is, sequences of numbers, which for theoretical purposes may be reduced to standard deviation measure These sequences can, like real functions of which they are a reduced case, be subjected to orthogonal partition and can be developed in series of sequences N being the number of elements in each sequence, all sub-sets of N-1 independent sequences, orthogonal or not, are 'complete', and all sequences of the whole set can be developed linearly in terms of any complete sub set The possibilities for the expression of a sequence in terms of 'factors' are therefore unlimited, a fact upon which Godfrey Thomson has insisted from a rather different point of view The theory can at this point be linked with that of linear substitutions or with that of unit vectors in multispace, but for the object in view there does not appear to be any advantage in doing so

I have obtained the conditions for the existence of a sequence having given correlation coefficients with a given sub set, and for the existence of a sub-set having a given array (mathematical sense) of correlation coefficients, together with the method of obtaining such a sequence and such a sub set In view of its great interest, I have also made a study of Spearman's two factor form following the above methods This form may be said to have the general validity claimed for it, it may be remarked, however, that there is another class of cases, besides those with negative correlations mentioned by Garnett, in which 'equiproportionality' (Dodd) does not imply the form I do not entirely agree with Prof Piaggio's statement that the arbitrary sequence i can be made as small as we please, this depends on the divergence of a certain series, which is not bound to diverge

When we come to application, distribution is all important An orthogonal partition of a sequence is of course not invariant for monotonic transformations, so that a partition such as Spearman's two-factor form is entirely dependent on the distributions adopted In statistical measurements as a rule, and in psychological measurements always, there is no measuring rod, so that distributions are at our mercy, and it is usual to make them fit some standard such as the curve of errors and to insist on the linearity of the regressions It is therefore on this standard distribution that the two-factor theory must rest, and not on the general method of partition. Karl Pearson has criticised Spearman's 'hierarchy' of correlation coefficients from the point of view of closeness of fit A mathematician with a less severe statistical morality will, however, have no objection to Prof Spearman making his fit perfect by small monotonic transformations or linear substitutions.

Orthogonal partition often connotes physical reality, as, for example, with harmonics in sound, but it must be remembered that in such cases the partition is completely specified by physical laws and conditions,

expressed as differential equations and boundary conditions Orthogonal partitions not so specified exist in infinite variety and have no physical significance. The question is, when do orthogonal partitions of sequences have a physical meaning ? Spearman has discovered a remarkable method for the analysis of statistical data , the greatest caution is necessary in interpretation H B HEYWOOD

Talking Beacon of the Cumbrae Lighthouse

IN NATURE of Jan 24, p 138, a statement appears regarding the talking beacon of the Cumbrae Lighthouse which calls for some comment The use of synchronous signals in air, water, and ether for navigational purposes dates, so far as I know, from experiments carried out near New York in 1911 These led to the installation of such signals on the Fire Island Lightship, where submarine bell and wireless dots were used to enable an approaching vessel to determine its distance from the lightship

In complete ignorance of this pioneer work, I contributed several papers to the Royal Society between 1915 and 1918 on synchronous signalling in navigation, and more especially on the prevention of collision at sea Two of these were reprinted on the North Atlantic Chart of the Hydrographic Office of the U S A for June 1917 A discussion of the subject appears in a book (London Fisher Unwin) in 1916 and finally, a general account up to date appears in the *Phil Mag* of July 1918

In the last mentioned paper (p 18) the de Forrest system, as used at Point Judith at the western approach to Narragansett Bay, is referred to ' A phonograph [= gramophone] speaks the words It cries the name of the lighthouse or lightship into the transmitter The system is entirely automatic The voice, translated into ether waves, reaches the antenna on the ship and is there re translated to the spoken words by a detector and telephone After every third repetition of the name of the station a much feebler voice speaks the warning ' You are getting closer , keep off ' "

Much of this is identical with the system installed at the Cumbrae Lighthouse , but Messrs Stevenson replace the feebler etherial message by the now well known method of synchronous signalling , that is to say, by signals issued simultaneously in different media This method is available in two forms signals travelling in air and in ether or signals travelling in water and ether The latter is far more trustworthy, but is only of use to such vessels as are fitted with receptors for submarine sounds

That risks attend the use of synchronous signals in which the atmosphere is one of the media is well known This risk arises out of the fact that ' silent areas ' under certain weather conditions may exist around the vessel—especially in fogs, *but also in quite clear weather* This risk is specially referred to in every " Sailing Directions " issued by the Admiralty " Sound is conveyed in a very capricious way through the atmosphere Apart from wind, large areas of silence have been found in different directions and at different distances from the origin of a sound, even in clear weather Therefore too much confidence should not be felt in hearing a fog-signal Taken together these facts should induce the utmost caution in closing the land in fogs The lead is generally the only safe guide " In my yachting days I have more than once experienced such conditions ; and, on one occasion, lasting for more than eight hours This was off the western coast of Ireland, between Loop Head and Tearaght Island

While it is very certain that the use of sound transmitted in air, as taking part in the estimation of distance, will in many cases prove available, it is questionable if this modification of the de Forrest system is wise The latter acts as ' a still small voice ' which is only heard when there is real danger and of course two or more observers may listen in Its directions reach the mariner as a spoken warning not to be misunderstood The voice cries to him again and again " Keep off—you are getting closer ", " Keep off—you are getting closer "

The addition of Dr de Forrest's warning voice to the name call of the gramophone at Cumbrae would be easy, and the whole system would become more generally reliable

I would like to add an expression of my complete concurrence with all that is said in the article on the Cumbrae Lighthouse beacon in the *Times* of Jan 13 regarding the noble work for coastal navigation accomplished by the late Robert Stevenson and his successors, Messrs C A and D A Stevenson

Effect of Desiccation on the Bed-bug (*Cimex lectularius*)

IT is well known that, during starvation, the bed bug, like many other insects, swallows considerable quantities of air, which serve to maintain the body volume in place of the food and tissues that are consumed I have recently observed that if the first stage larvæ of the bed bug are kept for several weeks in a moderately dry atmosphere (for example, 50

FIG 1 FIG 2

per cent relative humidity at 23° C), as the circulating fluids become less, the gut, containing bubbles of air, becomes herniated into the bases of the limbs, and may extend far down the femora (Fig 1)

If such insects are exposed now in a saturated atmosphere, although most of them die in a few days, others recover , moisture is taken in, and the bubbles of air disappear from the limbs On the other hand, if they are retained in the dry atmosphere, the gut wall eventually breaks, and bubbles of air are set free into the body cavity (Fig 2) The larva in this state is often still capable of sucking blood, and if given a moderate meal, both the bubbles in the gut and the free bubbles in the limbs disappear into solution During this process a certain amount of blood usually escapes into the body cavity, and the red corpuscles can be seen circulating in the blood of the insect I have had larvæ in which such corpuscles have continued to circulate, apparently unchanged, for three weeks—long after the blood in the gut had been completely digested

Apart from the curious circumstance of desiccation in an insect leading to a femoral hernia which perforates to give rise to a surgical emphysema, these observations present two points of interest first, that in the desiccated condition the larvæ are apparently hygroscopic and can absorb water vapour from a moist atmosphere (though the possibility of their taking up minute droplets of fluid condensed on the proboscis has not been entirely excluded), and secondly, that small foreign bodies, such as the blood corpuscles of vertebrates, can circulate in the blood stream, apparently indefinitely, without being removed by phagocytosis or otherwise

I am indebted to Dr H B Newham for taking the photographs of living *Cimex*

London School of Hygiene and Tropical Medicine, Jan 22

Conjunctival Halos

THE letter on this subject from Mr Sidney Melmore, in NATURE of Jan 3, leads me to describe an experience of my own which may be of some little interest Recently I was accidentally struck in the right eye with a dog whip, and I was conscious of a faint mistiness in front of that eye But I was surprised to find on looking at an electric light, on the same evening, that it was surrounded by a set of diffraction halos, two orders being visible Unlike the case described in Mr Melmore's letter, the space round the electric light was white and only the red ring of the first order halo was visible whereas all the colours of the second order could be seen A very approximate measurement of the first red ring gave its angular diameter as 7°, in fair agreement with the value quoted in Mr Melmore's letter An examination of the eye in a mirror showed that it was bloodshot, but revealed no trace of any abnormality in the part of the cornea immediately in front of the pupil The intensity of the halos decreased with time, and they disappeared completely after five days It would be interesting to know the nature of the small particles responsible for the halos, and how they were produced by the blow

A W BARTON

Repton School, Derby

THE probable explanation in Mr A W Barton's case is a transient œdema of the corneal epithelium, produced by the blow The basal corneal epithelial cells average about 10μ in breadth by 18μ in height, and the other epithelial cells are somewhat smaller These elements appear to be of about the right order in size

J HERBERT PARSONS

54 Queen Anne Street, Cavendish Square, W

Embryology and Evolution

IN the issue of NATURE for Feb 7, p 200, Mr Malcolm E MacGregor revives a form of vitalism that has lain dormant for a number of years, and well might it have been permitted to do so for as many more It is surely well recognised that science is only a conceptual scheme which presumably bears some relation to the percepts that it attempts to correlate What lies outside that scheme may indeed be of the greatest importance, but it is not science Mr MacGregor adduces no evidence that the force primarily operating the living cell is an external one His wishes would be equally fulfilled by some form of hylozoism, but then it would be very difficult to acclaim the view as likely to be a guiding star for biological advance If one wishes to hold such vitalistic theories as being true, one cannot remain immune from scientific attack except by rigid adherence to some form of dualism, such as that of the great Nicholas of Cusa. Thus, if it be contended, as he did, that there is an external form of experience subject to natural law but separate from an inner form that has no relation to such law and is beyond reason, then no scientific criticism is possible

The sterility of vitalistic hypotheses in the past leads one to doubt their fertility in the future, and the deification of entelechy does not carry us far

The Photo-Reaction of Hydrogen and Iodine Monochloride

WE are able to confirm the observations of D P Mellor and T Iredale [1] on the photo reaction between iodine monochloride and hydrogen, as against the photo inactivity of the mixture reported by Rollefson and Lindquist [2] A rapid photo reaction between these substances when not specially purified had been observed by us before the appearance of Rollefson and Lindquist's paper, the reaction, however, is much influenced by traces of impurities, for when special pains are taken to avoid contamination by organic materials, stopcock grease and the like, the rate of reaction under the influence of light is much decreased There remains, however, an easily measurable reaction under the influence of the light of a mercury arc The main products are hydrogen chloride (HCl) and iodine (I_2), no appreciable amount of hydrogen iodide has been found The photo reaction between iodine chloride and methane has also been established in this laboratory, the rate here is great compared with that of the hydrogen reaction Both reactions are being investigated in detail

Transmission of *Leishmania donovani*

WE have received the following telegram from New Delhi, dated Feb 19

"Lieut Col Shortt reports successful transmission of *Leishmania donovani* to Chinese hamster by bites of artificially infected *Phlebotomus argentipes* Hamster bitten repeatedly during twelve months, generalised infection found seventeen months after experiment began —Scientific India"

We understand that the telegraphic address "Scientific India" refers to the Scientific Advisory Board of the Indian Research Fund Association.

Scientific Congresses in 1931.

During the summer of this year five important scientific gatherings will take place in London, all of which will be of an international character The first of these will be the International Congress of the History of Science and Technology, the second the jubilee celebrations of the Society of Chemical Industry, the third the International Illumination Congress, and the fourth and fifth the centenary celebrations of the discovery by Faraday of electromagnetic induction and the centenary meetings of the British Association Though the programme of the International Illumination Congress includes meetings at Glasgow, Edinburgh, Sheffield, Birmingham, and Cambridge, the delegates will meet in London before visiting the provinces, while the meetings of the other bodies will be held entirely in London

Organised by Le Comité International d'Histoire des Sciences, of which the permanent secretary is Prof Aldo Mieli, the Second International Congress of the History of Science and Technology is supported by Le Comité International des Sciences Historiques, the Newcomen Society for the Study of the History of Engineering and Technology, and the History of Science Society, and the aim of the Congress is to provide opportunity for intercourse and exchange of thought between all those who are interested in the various departments of the history of science and technology The programme has been arranged to cover the period Monday, June 29, to Friday, July 3, and the headquarters of the Congress will be the Science Museum Besides scientific communications, there will be social gatherings, visits to historic institutions, and excursions to places of scientific interest The president is Dr C Singer, the honorary treasurer Sir William Bragg, and the honorary secretary Mr H W Dickinson, Science Museum, South Kensington, S W 7, from whom further particulars can be obtained The Congress, it may be added, originated with the Comité International d'Histoire des Sciences, which was founded at Oslo on Aug 17, 1928, and meets annually in Paris

The jubilee celebrations of the Society of Chemical Industry, it has been announced, will be of a domestic character, the functions being thrown open only to members and a very few distinguished guests who will be the recipients of special honours The Society was founded in 1881, and to-day has upwards of 7000 members, associate members, and subscribers The meetings will commence on July 13 and will extend over the succeeding seven days It is hoped the Lord Mayor of London will open the proceedings by receiving the delegates at the Guildhall, and succeeding events will include the annual dinner, the annual general meeting, the delivery of the presidential address, and the presentation of the Society's Medal Visits to many works typical of the manufactures of London are being arranged, the Chemical Engineering Group of the Society is arranging an exhibit of special recording and measuring instruments in the Central Hall, Westminster, where there will also be an exhibit of British chemical plant arranged by the British Chemical Plant Manufacturers' Association. To mark the occasion permanently, Dr Stephen Miall, editor of *Chemistry and Industry*, is writing a history of the chemical industry, to be published at a low cost immediately prior to the meeting, and a special jubilee number of the *Journal* of the Society will be published containing reprints of outstanding papers, biographies of presidents, medallists, and honorary members, and a history of the Society While the preliminary programme was being arranged, the late Lord Melchett held the presidency of the Society, but he has now been succeeded by Sir Harry McGowan The headquarters of the Society are at Central House, 46 Finsbury Square, E C 2, Mr H J Pooley being the general secretary

The meeting of the International Illumination Congress, the ninth of its kind, will be divided into two parts, the first part consisting of a Congress which will be held on Sept 2–12, and the second part consisting of meetings of the technical committees of the International Commission on Illumination, to be held on Sept 13–19 The Congress, of which Mr C C Paterson is the president, is being organised by the National Illumination Committee of Great Britain, in co-operation with the Illuminating Engineering Society, 32 Victoria Street, S W 1, Col C H S Evans being the honorary general secretary After assembling in London on Sept 1–3, the delegates will then spend two days at Glasgow, three days at Edinburgh, two at Sheffield, two at Birmingham, and the remainder of the time, Sept 13–19, at Cambridge At the latter place will be held the plenary session of the International Commission on Illumination A comprehensive list of subjects for discussion has been drawn up, and papers will be presented on the lighting of factories, offices, houses, vehicles, streets, museums, and lighting for traffic control, together with others on lighting for aviation and navigation, flood lighting, architectural lighting, laboratory technique, and the lighting of mines Many institutions are represented in the general council of the Congress, the chairman of which is Lieut-Col K Edgcumbe The first three International Illumination Congresses were held at Zurich, and the others have since been held at Berlin, Paris, Geneva, Bellagio, and Saranac, New York

We have on a previous occasion referred to the general arrangements for the commemoration of the centenary of Faraday's discovery, which are in the hands of the Royal Institution and the Institution of Electrical Engineers While these two institutions have joined forces in making the plans, they are indebted to other societies for their cooperation Thus, the Royal Society will entertain the delegates to the celebrations, the Federal Council for Chemistry will participate in the arrangement of the Faraday Exhibition, and assistance has been offered by Government, university, and other bodies with scientific interests The provisional programme includes the reception of the delegates in the Lecture Theatre of the Royal Institution, and the Faraday commemoration meeting at the

Queen's Hall on Sept 21, conversaziones at the Royal Institution and the Institution of Electrical Engineers on Sept 22, and the opening of the Faraday Exhibition at the Albert Hall to the public on Sept 23 This exhibition will remain open for about ten days, and it is hoped to publish a catalogue and description of it The preparation of a souvenir of the whole celebrations is under consideration, and progress is being made with the preparation for publication of Faraday's famous diary Of the six or eight volumes in which the work will ultimately be completed, it is hoped to have one or possibly two ready by September

The second day of the Faraday celebrations, Sept 22, will coincide with the opening of the summer meeting of the Institution of Electrical Engineers, while the third day, Sept 23, will be the commencement of the centenary meeting of the British Association for the Advancement of Science, which has not hitherto met in London During the afternoon of Sept 23, Lieut Gen the Right Hon J C Smuts will be installed as president of the British Association and a reception of delegates will be held in the Albert Hall, this arrangement allowing the members to have a private view of the Faraday Exhibition On the same evening General Smuts will deliver his address at the inaugural general meeting in the Central Hall, Westminster The sectional and other scientific transactions will be carried on daily from Thursday, Sept 24, until Wednesday, Sept 30, inclusive For the majority of these transactions meeting rooms will be used in and near Exhibition Road, South Kensington, while the reception room will be in the Great Hall of the University of London A preliminary notice has been issued by the Association giving the names of the presidents of the thirteen sections, among whom are Sir J J Thomson, Sir Alfred Ewing, Sir Halford Mackinder, Sir Harold Hartley, Sir C Grant Robertson, and Sir John Russell The usual programme of visits and excursions will be arranged, and in view of the very large number of institutions and buildings, houses, and memorials in London connected with the scientific men of the past, and the wealth of scientific work now being done in the metropolis, these should prove of wide and general interest A large attendance of scientific workers from both the Dominions and foreign countries is expected, for whom the Association hopes to obtain private hospitality by residents in London The full preliminary programme is expected to be issued in April, and this will be obtainable from the Secretary, British Association, Burlington House, W 1

In addition to these congresses, two other scientific gatherings of unusual interest will be held in Great Britain At Manchester on Mar 17 the Manchester Literary and Philosophical Society will commemorate the 150th year of its foundation, while at Cambridge on Oct 1–2 the centenary of the birth of James Clerk Maxwell will be celebrated Founded in February 1781, the Manchester Literary and Philosophical Society will always be associated with the work of Dalton, who for half a century was a member Other distinguished scientific men connected with the Society include Joule, Sturgeon, Hodgkinson, Fairbairn, Nasmyth, Wilde, Osborne Reynolds, Balfour Stewart, and Roscoe The commemoration will include an address in the Athenæum Hall by Sir J J Thomson, to whom the Dalton Medal will be presented, and a dinner in the Midland Hotel During the week the Society's house, 36 George Street, will be open to visitors At the Maxwell centenary celebrations at Cambridge, addresses will be given by Sir James Jeans, Sir Joseph Larmor, Sir J J Thomson, and Profs Einstein, Langevin and Planck Maxwell was born on June 13, 1831, and died on Nov 5, 1879 He was the first Cavendish professor of experimental physics and the founder of the great school of experimental physics at Cambridge His contributions to optics, geometry, molecular physics, and other subjects are to day less widely known than his fundamental work on electromagnetic theory, and his connexion with Faraday makes it appropriate that his centenary should follow the September celebration of the centenary of Faraday's discovery of electromagnetic induction

Glasses for Use with Invisible Rays *

By Dr S English, Holophane Research Laboratory

WHENEVER light is produced, invisible radiations—ultra-violet (U V) or infra red (I R)—are, almost without exception, produced at the same time Glasses which are transparent to the visible rays are not necessarily transparent to either the ultra-violet or infra-red, and similarly, opacity to one set of radiations does not imply opacity to the other two sets In order to control these invisible rays, therefore, it is necessary to have ranges of glasses for transmitting and for absorbing these various bands of rays

Ultra Violet Radiation

Of recent years the extraordinary biological activity of a small band of ultra-violet rays lying near the extreme end of the sun's spectrum, and extending from this wave-length (295 $M\mu$) up to about 320 $M\mu$, has established the fact that though ordinary glass, as used for windows and artificial lighting equipment, is transparent to the longest ultra-violet rays, it becomes opaque at about 310 320 $M\mu$ It is thus useless for transmitting rays of the biologically active wave-lengths Several types of glass have been developed which are transparent to these so-called 'health rays', and to a limited extent to radiations of rather shorter wave lengths than are found in the sun's spectrum

Investigations in this field have proved that silica and boric oxide are the best two materials for making glass with a good transparency for the ultra-violet, while iron oxide and titania are the two most dangerous oxides in this respect In

* Substance of a paper read before the Illuminating Engineering Society on Dec 12

making U V. glass, besides reducing the amount of iron oxide entering the glass from various sources, it has been found necessary to melt the glass under chemically reducing conditions, for ferric oxide reduces the U V transparency much more than does a corresponding amount of ferrous oxide For this purpose organic reducing agents are generally used, but recently, in some cases, inorganic reducing agents have been used very successfully With these inorganic reducing agents it is possible to obtain a higher proportion of the total iron oxide content of a glass in the ferrous condition, and as a result the colour of the glass through a considerable thickness is pale blue, whereas the colour of glass reduced with organic agents is pale green or blue green, or it may be a pale amber colour if too much carbonaceous matter has been used

In connexion with that much-debated matter, the ageing of U V glasses, it has been shown that certain types of glass more easily lose a certain proportion of their transparency to the ultra-violet than do others This loss of U V transparency appears to be due to the reoxidation of the ferrous iron in the glass to the ferric state, a process which proceeds slowly under the influence of direct sunlight until an equilibrium between the relative amounts of the two oxides is reached When once this equilibrium is reached, no further loss of U V transparency occurs unless the conditions of exposure are altered The extent of this loss of U V transparency depends on the total iron oxide content of the glass and on the conditions of manufacture, it varies from so low a figure as 7 per cent at 300 Mμ for one type of glass up to 20 per cent or more for other types

For the manufacture of medical and scientific U V lamps, clear fused quartz is an ideal material, but it is too transparent to the shorter ultra violet rays and too expensive when worked into the desired sizes and shapes that are required for certain new types of U V lamps These lamps, it is claimed, give sufficient ultra-violet light of the active wave-lengths to produce a light erythema, but, it is also claimed, they are safe to use—continuously without medical supervision—either as a substitute for, or in parallel with, ordinary artificial lighting One of these lamps consists of a daylight blue globe of U V transparent glass surrounding a tungsten filament, which is distinctly over-run, so much so that its average life is reduced to 300 hours Another lamp has a clear U V glass bulb containing a drop of mercury, a tungsten filament, and tungsten electrodes between which a mercury vapour arc is struck almost as soon as the lamp is switched on, the heat from the filament being sufficient to vaporise enough mercury to start and maintain the arc (Fig 1) A third lamp of this type is a low-pressure mercury arc enclosed within a vitreosil tube which is surrounded by a framework carrying sheets of U V glass The lamp is meant for use along with ordinary artificial lighting units

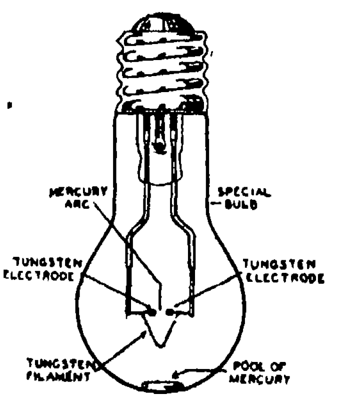

FIG 1 —New type of U V lamp

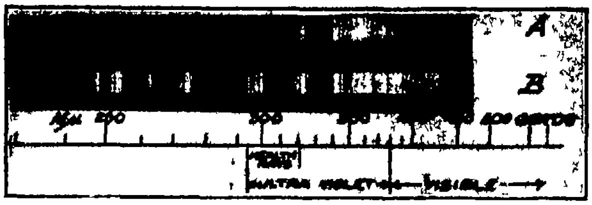

FIG 2 —A, iron arc through Wood's glass, B, iron arc

Glasses containing sufficient nickel oxide on a potash base to colour them a very deep blue are so deep that in thicknesses of 3 mm they are opaque to ordinary light, but are transparent to ultra-violet rays from about 390 Mμ down to about 310 Mμ (Fig 2) They are referred to as Wood's glasses With such glass it is possible to have a room completely dark but flooded with ultra violet rays that only need to impinge on suitable fluorescent materials to reveal their presence One such material is the so called canary glass, which owes its fluorescent properties to the presence of a small percentage of uranium oxide on a soda lime base Under the action of ultra-violet rays, this glass shows a very strong greenish-yellow fluorescence Certain other glasses show a weak fluorescence, but none of them is in any way comparable to uranium glass in this respect Besides its attempted use in invisible signalling, Wood's glass is finding many avenues of usefulness in research and commercial laboratories

For absorbing ultra-violet rays while at the same time transmitting the visible spectrum without very much selective absorption, there are several glasses available, all based on Sir William Crookes's work, and all containing, as an essential constituent, cerium oxide If selective absorption in the visible region is not objected to, then an amber-coloured glass made by the inclusion of iron oxide and manganese dioxide in the batch is very effective in absorbing ultra violet rays

INFRA RED RADIATION

On turning to the infra-red rays, extending from 0 78 μ upwards, we again have three types of glass (1) for transmitting both visible and infra-red rays, (2) for transmitting the visible and absorbing the infra-red, and (3) for absorbing the visible and transmitting the infra red Considering them in this order, fused quartz, which of course transmits the vision rays freely, also transmits the infra-red radiations up to a wave-length of about 5 μ It is not to be expected that glasses containing 70-75 per cent of silica will show any better infra-red transparency Soda and lime, the other principal constituents of ordinary glass, appear to cause a

slightly decreased infra-red transparency, but this may be due to small amounts of impurities that are usually found in such glasses

Sir William Crookes, in his work published in 1914, showed that many oxides conferred on glass the property of absorbing the infra-red rays to varying extents Most of these oxides also gave a distinct colour to the glass He also showed that by far the most effective material for this purpose was iron oxide melted into the glass under reducing conditions In his work Crookes measured the infra-red radiation transmitted through his glasses by the total heating effect His general conclusions have recently been confirmed by the work of Gehlhoff, Schmidt, and Thomas, who have determined the infra-red transmissions at various wave-lengths

Several heat-absorbing glasses are available They all employ iron oxide in the reduced condition, the only essential difference being the means that are employed to obtain the iron oxide in the ferrous state Generally the iron and its reducing agent are introduced together by using iron oxalate as Crookes did Recently, however, attempts have been made, with a certain degree of success, to use inorganic reducing agents, which retain a greater proportion of the iron in the ferrous state Such glasses are blue-green in colour, instead of the green of ordinary iron-containing glasses

Measurements show that the heat absorption of glasses of this type is to a certain extent related to the colour of the glass, but there is no close parallel, as is shown in the accompanying table

Light Transmission and Heat Absorption of Various Glasses, 2 5 3 0 mm Thick.

Glass	Percentage heat absorption.	Percentage light transmission.		
		Red	Green	Blue
H (Clear)	74	59	72	71
T (Clear)	72	59	71	71
C (Cath)	93	17	36	35
A (Clear)	79	59	75	75
5 (Experimental)	86	50	70	69
12 (Experimental)	93	25	45	44

As a last type of glass to be considered, there is a very interesting glass which has the power of absorbing all visible rays but transmitting infra-red rays Such a glass, of course, appears black in thickness of 2 mm and upwards, but in very thin sections it has a reddish amber colour As a means of invisible signalling, this glass has almost, if not quite, superseded Wood's glass, since infra-red rays are easier to produce in quantity than ultra-violet rays , they also have the great advantage of carrying farther, as they are not so easily absorbed by the atmosphere For burglar alarms and apparatus of that type, this glass has an interesting field of usefulness

British Industries Fair.

THE British Industries Fair, 1931, to which brief reference was made in our last issue (p 281), has exceeded its previous records in the total area occupied by the stands, in the number of exhibitors, and probably, also, so far as the evidence is available at the time of writing, in the number of overseas and home buyers, as well as of the general public, that have visited it The integrated effort to demonstrate visually the extent, variety, and quality of the products of British industry required this year no less than four separated, but not unrelated, exhibitions for the light industries, at Olympia, London , for the heavy industries, at Birmingham , for textiles, at the White City, London , and for artificial silk goods, at the Albert Hall, London In the critical industrial period through which the country is now passing, the Fair was a remarkable and bold achievement, and tribute must be paid to the Department of Overseas Trade, to the Birmingham Chamber of Commerce, and to the various trade and industrial organisations, as well as to individual firms, that co-operated in its organisation Information is not yet available, but will be eagerly awaited, as to the business orders that have been received for British goods, as the direct result of the Fair

It will not be possible to review, even cursorily, the exhibits shown at the four separate sections of the Fair mentioned above, but it may be worth while to record a general impression of the exhibitions at Olympia It is difficult to believe that any visitor could thoughtfully go through the Fair without being greatly impressed by the vast range, the great variety, the excellent quality, and often, be it said, the great beauty of the goods displayed Despite the disheartening aspect of our unemployment figures and the faintness of our hopes of an early industrial revival, the evidence that Olympia afforded of the vigour and quality of so many British industries was reassuring and uplifting An industrialist, recently returned from journeying overseas, related that, in foreign countries and in the British dominions overseas, he had again and again noted how confident was the expectation that, whatever might happen in other countries, Great Britain at least would win through the difficulties of the world slump What could be seen at Olympia went far to justify this confidence In the heavy industries and in the great staple exporting industries, Great Britain has been for so long in the forefront that the quality of their products has almost come to be taken for granted, but even in those lighter industries associated in the popular mind with foreign manufacture—for example, toys and certain kinds of fancy goods—the exhibits at Olympia provided striking evidence of the progress that has been made by British manufacturers

The grouping of the exhibits according to industries was not only convenient for the buyer and

visitor, it necessarily created a series of mass effects also, so that it was impossible to escape getting, from each group, a general impression of the respective industry as a whole In this regard, the china, earthenware, stoneware, and glassware exhibits formed a notable display, which included, it may incidentally be noted, some remarkably beautiful developments in decorative glassware It is well worth the consideration of future exhibitors how they may develop what may be called the organised group exhibit There can be no doubt that, so far from exhibitors losing anything by close association of their exhibits with those of similar, and even competitive, firms, they gain in mere advertisement value from the mass effect produced by the associated exhibit The individual firm must ultimately benefit from any good impression created of the whole industry of which it is a constituent

In this connexion, special praise should be given to the exhibit of the British scientific instrument manufacturers, which this year excelled, in area, in the number of exhibitors, and in the range and variety of exhibits, the achievement at last year's Fair The total effect of the two great contiguous stands on which the British optical and scientific instrument manufacturers had arranged their exhibits was an assurance of the vitality and a guarantee of the future of this important British industry Perhaps one of the most striking features of these associated exhibits was the manifestation of the extent to which scientific instruments are being used in all sorts of other industries in which, not so very long ago, they were unknown In order to direct attention to this modern development, the exhibiting manufacturers published a brochure, for distribution at the Fair and otherwise, on scientific instruments in industry, from which it is interesting and encouraging to learn *inter alia* that ninety per cent of the cinematograph-taking lenses used at Hollywood are of British manufacture, and that an equal or even a greater percentage of the best cinematograph projectors used in the United States are fitted with British lenses The exhibits on the combined stand of specimens of optical glass, of photographic lenses, and of prismatic binoculars lent point to the remarkable tribute paid to the superiority of certain British over corresponding foreign optical products in a letter by Dr C V Drysdale, Director of Scientific Research at the Admiralty, which appeared in the *Times* of Feb 14 That letter, as its writer claimed, but confirmed and amplified the statement made in a letter in the *Times* of Oct 19, 1925, from Dr Drysdale's predecessor in office, Dr (now Sir Frank) Smith

"It is a commonly held belief that optical instruments and optical glass of British manufacture are inferior to the instruments and glass produced by certain well advertised Continental firms and sold in large quantities in this country I wish to state that this belief is erroneous, and that it is based on prejudice rather than upon a knowledge of the facts Comparative tests made with rigid accuracy in the laboratory, and trials under stringent service conditions, prove that British optical instruments and glass are inferior to none"

We have not space to notice, by way of example, more than a few of the instruments exhibited by the British scientific instrument manufacturers Various types of temperature indicating and recording instruments, for use in industry, were shown by the Cambridge Instrument Co, Ltd, and by Negretti and Zambra The display of microscopes by R and J Beck, Ltd, W Watson and Sons, Ltd, James Swift and Sons, Ltd, and Charles Baker ranged from the simple student's form to the elaborate research microscope, and included types designed specially for industry Adam Hilger, Ltd, showed, besides an interferometer, a colorimeter and a spectrograph, a 'steeloscope' which has been produced for the rapid identification, by visual observation by unskilled labour, of different varieties of steels Newton and Co showed an epidiascope, ingeniously fitted with mirrors so as to increase the illumination of the object to be projected, and Charles Baker had an epidiascope fitted with a fan to prevent the evil effects of overheating Among the navigating instruments shown, reference may be made to a dead beat compass shown by Henry Hughes and Son, in which increased steadiness and damping are secured by an ingenious use of fine radial filaments Messrs Ross, Ltd, exhibited, besides their great range of photographic lenses, a cinematograph projector and a telescope of exceptionally light design, in which the body tube is of light fabric instead of metal, and which was mounted on a light and easily folded tripod Ensign, Ltd, had an interesting and recently designed aerial camera

Of the other scientific exhibits displayed at Olympia, mention must be made of the Chemical Section The Imperial Chemical Industries, Ltd, relied mainly, as last year, on a small cinema in which films were shown of the manufacture of some of their typical products, as well as of the social welfare work associated with the various units of this great organisation The stands of the gas companies and of the various chemical manufacturing firms showed almost a bewildering range of exhibits, from the simplest raw materials to the most refined analytical reagents and 'fine' chemicals Hopkin and Williams, Ltd, for example, showed a collection of radioactive uranium bearing minerals and the products obtainable from them, and also an exhibit of barium sulphate for X-ray diagnosis

It would be but random selection to refer further to particular exhibits Taking the Fair, as it could be seen at Olympia, as a whole, it was a noteworthy and encouraging demonstration that Great Britain is still in the forefront of the manufacturing nations of the world It is to be hoped that all the thoughtful planning, the careful organisation and the zealous co-operation that went to the making of the Fair will have their merited reward in a great and needed stimulus to British industry

Obituary.

The Hon Sir Charles Algernon Parsons, O M, K C B, F R S

By the death of Sir Charles Parsons on Jan 12, while on a voyage to the West Indies, the world has lost the greatest engineer engaged in the production of power from steam since the time of Watt It is due to his genius and perseverance that the steam turbine now produces practically all the electricity derived from steam power and every fast ship of large size, both naval and mercantile, is driven by steam turbines

Sir Charles, who was in his seventy seventh year, was the fourth and youngest son of the third Earl of Rosse, who built the great 6 ft telescope at Birr, Ireland He was educated privately and at Cambridge, where he was eleventh wrangler He became a pupil at Elswick Works and in 1883 joined Clarke, Chapman and Co of Gateshead, where he made his first steam turbine of 4 h p , which ran at the unprecedented speed of 18,000 revs per minute The design of the dynamo to be coupled to it—and it must be remembered that the design of electrical machinery was in its infancy then—was quite as great a feat as the steam turbine itself With increasing size, and improvements in design, the efficiency of the steam turbine increased until in 1888 a 32 kw machine running at 8000 r p m with 100 lb per sq in saturated steam and non-condensing gave a consumption of 51 lb per kw hour, a figure that would be good even at this day

In 1889 Parsons parted company from Clarke, Chapman and Co and started the Heaton Works, Newcastle-on-Tyne, to manufacture steam turbines and other steam and electrical machinery Here he met with the great setback that Clarke, Chapman and Co retained his original patents for turbines with the steam flow parallel to the axis He, however, designed a turbine clear of the original patents with the steam flowing radially, which, with the addition of condensing, culminated in a 100 kw turbine running at 4800 r p m giving the then record consumption of 27 lb per kw hour with 100 lb per sq in steam pressure, 50° F superheat, and 27 in vacuum

In 1894, however, as Clarke, Chapman and Co had failed to make a success of the steam turbine, Parsons got back his original patents for a fraction of the sum originally asked for them, and the parallel flow turbine was reverted to, in a form, except for size and improvements in construction and design, essentially the same as the reaction turbine of to-day In the forty-five years that have elapsed from the time he made his first turbine, the size has increased from the 4 kw turbine of 1884, which is now in the Science Museum, South Kensington, to 50,000 kw and even 200,000 kw

In the same year Parsons resolved to apply the steam turbine to marine propulsion, and an experimental boat, the *Turbinia*, of 40 tons displacement, was built At first it had one turbine, but, on account of what was then the little-known phenomenon of cavitation, not more than about 20 knots was attained For one turbine, three in series were substituted, and on each of the three shafts there were three propellers, and thus, in 1897, the then record speed of 34 knots was attained Two destroyers followed, one of which attained on trial 37 knots—which, it must be remembered, was obtained with coal and not oil fuel Unfortunately, both these were lost at sea about 1901, due to causes which had no relation to the turbines Soon afterwards two comparison ships, the *Amethyst* fitted with turbines and the *Topaz* with reciprocating engines, were built by the Admiralty, with the result that the performance of the turbine ship was much the better As a result, in 1905 turbines were fitted into the battleship *Dreadnought*, and then became the standard for the Navy On the mercantile side the growth was also very rapid, culminating in the *Mauretania* of 40,000 tons displacement and 68,000 s h p , which was designed in 1904 and finished in 1907, or just ten years after the *Turbinia* of 40 tons displacement In 1912 the difficulty of a slow-speed turbine having to be coupled to a high speed propeller was overcome by the introduction of gearing enabling each to run at the most suitable speed, and geared turbines have now become standard practice In 1926 a further step was made in the *King George V* , a Clyde passenger boat, where a steam pressure of 550 lb per sq in was adopted

Besides steam turbines, Parsons had many other interests he made several experiments with very high pressures and temperatures, a 2000 ton press and large storage battery being installed for this purpose, chiefly in the hope of being able to make diamonds but without success He also experimented on still higher pressures by firing steel bullets into a block of steel having a hole the same diameter as the bore Another experiment was to fire a large shot into a chamber containing a mixture of acetylene and oxygen, where it was estimated a temperature of some 16,000° C was attained on the explosion of the gases None of these gave any result The reproduction of sound was another of his activities , he made a valve worked from a gramophone or violin which, when supplied with compressed air, gave a great augmentation of sound combined in many cases with improved quality

Parsons was always interested in optical work largely inherited from his father, and so early as about 1887 devised greatly improved methods of producing search light reflectors, resulting in Heaton Works constructing nearly all the parabolic search light reflectors made in Great Britain He also made reflectors with one axis a parabola and the other a hyperbola or ellipse, so as to give a flat beam for use on the Suez Canal or other purposes By taking over the Derby Crown Glass Works where he was able to make many improvements in the manufacture, he to a large degree saved the production of optical glass in Great Britain , and he also had a controlling interest in Messrs Ross Ltd , makers of binoculars and other optical instruments He also took over the telescope works o

Sir Howard Grubb, F R S , which are now carried on at Walker Gate, Newcastle-on-Tyne

Sir Charles was a firm believer in the importance of research in industry, and very large sums were set aside for this purpose Also, accurate tests were invariably made of each machine as it was made, so as to give data for subsequent designs He also firmly believed in the utilisation of what may be called highly educated labour, and had always on his staff university men and others with high education, but in all cases it had to be combined with good practical knowledge

The Royal Society elected Sir Charles a fellow in 1898, and he served on the Council in 1907–9, being a vice-president in 1908–9 , he was awarded the Copley and Rumford medals He was made a K C B in 1911 and received the Order of Merit in 1927 He was given many honorary degrees by various universities, and among other medals had the Grashof Commemoration medal of the Verein Deutscher Ingenieure, the Albert medal of the Royal Society of Arts, and the Faraday medal of the Institution of Electrical Engineers He was an early member of the Advisory Council of the Department of Scientific and Industrial Research, and was on numerous other committees

Sir Charles married in 1883 Katherine, daughter of W B Bethell, of Yorkshire, and had one son, who was killed in the War, and one daughter He was a large benefactor to science, giving £5000 to the Royal Institution and £10,000 to the British Association, besides numerous gifts to various institutions GERALD STONEY

IT is difficult to write of Charles Parsons, a great inventor, one to whom civilisation owes more than a friend's feeble pen can well express Try to picture the world without his inventions, in the days when Atlantic travel took place in ships like the old *Scotia* of the Cunard Line, or the first *Oceanic*, which, when the White Star Line started some sixty years ago, created so much interest on Merseyside Contrast these with the *Mauretania* and the *Lusitania*, the first great ships propelled by Parsons' turbine, or to come to our own days, with the Cunard *Aquitania* or the *Bremen* of the North German Lloyd Line Maybe in 1931 we pay too much attention to speed, but time has a high value, and the minutes saved for useful work by the invention, which startled the world when the *Turbinia* first showed herself at the Jubilee Review in 1897, total many millions in number These are due to Charles Parsons

But for far more than speed and comfort in ocean travel are we indebted to the turbine and its inventor Imagine modern life without electric power This is neither the place nor the opportunity to collect statistics and estimate the percentage of that power generated through Parsons' work on the turbine, generated, too, in a manner so efficient that it is scarcely possible to hope for an improvement— unless, indeed, another Parsons shows us how to use atomic energy For Parsons was never content to leave an invention until it was nearly perfect, nor was he stopped by difficulties which to many seemed insuperable At first, the turbine was not a great success , he knew how efficient it ought to be, and he reached his mark Kelvin well described his invention as the greatest advance in steam practice since the days of Watt

So, too, with other problems Parsons tried to produce a diamond, and at the end of his life agreed, no doubt, as Prof Henry E Armstrong has told us, that there is no valid evidence to show that it can be obtained by any of the hitherto asserted means , but the work is there, of the highest value—a contribution to knowledge impossible for any but a great man, applying to the problem all the resources of the engineer, all the inventive power of a brilliant mind

Nor were Parsons' powers less shown in his more recent work Telescopes and optical glass had for him a hereditary interest and so he applied his genius to replace English optical glass in the position it held before the days of Abbé and Zeiss, and he did it, while in quite recent years he was devoting himself to further Hale's plans for a giant reflecting telescope

Parsons made no special mark at Cambridge, where he graduated as eleventh wrangler in 1877 After the usual training of an engineer, he set to work to develop the turbine, but it was not until the end of the century that he received any distinct recognition

No one meeting Parsons casually would have recognised in the gentle, modest man, somewhat quiet and hesitating in speech and manner, one of the world's great benefactors In public he said little, but interest him in a problem, ask his advice on some knotty point of scientific or engineering practice, give him, perhaps, a little time for quiet thought, and your problem was solved, or if solution was not at once to be found, you were set on a track promising to lead to the desired end Moreover, if the attainment of that end seemed of importance, you secured for the rest of your journey the support and assistance of a most wise counsellor and, what is more, a most kind friend

For Charles Parsons was that to all who earned his friendship , and we, who have enjoyed it for the last twenty five or thirty years, are the poorer for his loss, happy though we are to have known such a man, and to have learned from him some of the elements of true greatness

R T GLAZEBROOK

I FIRST met Sir Charles Parsons when he was appointed by the Lord President to the Advisory Council for Scientific and Industrial Research, on the resignation of Prof Bertram Hopkinson owing to pressure of War work Thus he was not an original member of the Council as has been stated in some obituary notices, though he joined it in the course of its first year of work His acceptance of the office was a proof of his willingness to subordinate his personal views to the common good, for it was no secret that he thought the national

organisation of scientific research for industrial purposes would have been better placed under the ægis of the Royal Society than under the State Yet he was as regular and active a member of the Council at its long and anxious deliberations as any of that brilliant group of seven distinguished men of science who formed the first Advisory Council As he came to realise that the formulation of policy lay in fact, as it was intended to lie, with the Council rather than with the Minister or his officials, I think his old doubts disappeared, though he was always a little inclined to be suspicious of the 'machine', which, as the range of the Council's activities grew—and it grew very rapidly—necessarily entailed a great increase in administrative business and a corresponding enlargement of the Department This watchfulness was all to the good of the cause, for the bureaucratic spirit will always be destructive of the aims and ideals of any organisation for the promotion of research, and more particularly industrial research, in which the utmost degree of co-operation between interested and independent bodies and the largest measure of decentralisation are essential to success

Parsons was essentially a shy man, and his interventions in discussions at the Council were generally brief, and often by way of critical question rather than dogmatic statement The longest speech I ever heard him make was a remarkable analysis of the conditions necessary for the successful application of new inventions or processes in industry, made before a departmental committee appointed by the Lord President to consider the problem of adequate rewards to scientific workers in government service for discoveries made by them in the course of their employment He emphasised the comparative cheapness in time and money of small-scale laboratory research, and the high scientific ability, the costliness, and the patience needed for translating a new technique or process or device into industrial practice He maintained that for this part of the work, where the risks were greatest, the greater reward was justly given As a great industrialist himself, he would have liked to see, though he realised its inherent difficulty, direct assistance given to selected firms in working new ideas on a manufacturing scale Failing that, he was a whole-hearted supporter of the policy of establishing co operative research associations in the industries, for he hoped they would have a freedom in dealing with individual firms which was impossible to a department of State

In two directions this belief of Parsons was influential He was closely associated, as an original member of the Fuel Research Board established in 1916, with the late Sir George Beilby's scheme for the station at East Greenwich, where research into fuel problems is conducted both on a laboratory and a full manufacturing scale, and again, it was his active support which helped to secure for the British Scientific Instruments Research Association more generous and continuous assistance than was given to any other of these organisations A letter from the Director of Scientific Research and Experiment at the Admiralty to the *Times* of Feb 14, in which he records the proved superiority of British optical glass and optical instruments, is evidence of the wisdom of this policy Parsons was himself a prime contributor to this result, for after his retirement from the Advisory Council in 1920, he became not only chairman of the Scientific Instruments Research Association, but also successively the owner of the Derby optical glass works and the controlling influence in the famous firms of Sir Howard Grubb and Messrs Ross and Co

Parsons entered the glass and instrument industries with the same high courage which had created his great engineering firms, and certainly with no expectation of monetary reward He knew the conditions too well for that, but he remarked that he believed a good man of science ought to be able to make optical glass without a previous training in glass technique, and his family traditions gave him pride in a conquest which would benefit both science and his country I have always thought that his interest in glass had its origin in the work of his father, and in the researches he himself undertook at Newcastle on the large reflectors he manufactured there for search lights

I remember, when Parsons took me over his works shortly after the War, that he showed me the shop in which these great reflectors were made, and explained how he had solved the problem of annealing them to withstand the strains set up in use It was impossible to walk with him through his great works without realising that the research spirit informed the whole undertaking, while simultaneously the practical engineer was in control of every part He was intimately acquainted with every machine in his shops, and again and again he would stop to explain how a weakness had been removed or better performance achieved by his personal intervention Yet as we moved over to the small building in which he had for years experimented in the artificial production of diamonds, one began to realise the range of his interests, and his willingness to expend large sums and all his ingenuity on problems of no immediate practical importance

Parsons was not, I should think, an altogether easy man to work with No genius is Like most shy men, he was a keen observer and sometimes a sharp critic of others When he set himself to a task, he would work at it continuously, so he told me, for twenty-four or thirty six hours or longer at a stretch This intensity of application and speed must often have left his collaborators and assistants gasping behind him Yet no man, I believe, did more than he to train his men in the method of his work Had he been one half as careful of his own health as he was for that of his staff, this grave loss to industry, to science, and to Great Britain might have been postponed

H FRANK HEATH

WE regret to announce the following deaths:

Mr H O Beckit, reader in geography in the University of Oxford, on Feb 19, aged fifty-six years.

Mr G E Birkett, director of the Manchester and District Radium Institute, on Feb. 5, aged thirty-seven years

News and Views.

According to Dr. S. C. Lind, director of the School of Chemistry, University of Minnesota, research has shown that starting with a single, simple mother-substance, a complex mixture of hydrocarbons such as occur in natural petroleum may be synthesised by suitable reactions The latter include the application of heat and pressure and, what is perhaps more novel, the bombardment of the initial substance with the alpha rays from radioactive compounds The *Daily Science News Bulletin* issued by Science Service, D C, records a recent communication of Dr Lind's to the American Association for the Advancement of Science, and quotes him as saying "The simplicity of such a mechanism may lend indirect support to the old idea of an inorganic origin from one or a few hydrocarbon gases such as might be produced by the action of water on metallic carbides in the earth's interior On the other hand, it does not preclude animal or vegetable origin, but strongly suggests that the primary material, whether gaseous, liquid, or solid, is later subjected to thermal or ionic agents or both, which produce the complexity found in Nature"

While we may discern radioactivity in a new, but none the less possible, rôle in this (Dr Lind's) theory of petroleum genesis, any support to the moribund inorganic hypothesis, whether direct or indirect, must inevitably be completely razed by the overwhelming geological evidence now available with the progress of time and discovery of vast oilfields, the data of oil occurrence of which were not available to enlighten the earlier views But there is decided merit in the postulation of radioactivity as effecting some degree of ionisation of organic matter during the baffling process of destabilisation and actual formation of oil It is this phase of the genesis which is still so hazy, and anything that chemists can do to throw light on the reactions involved, either mechanism or process, will prove of unquestioned service to science But is radioactivity a potential function in the type of environment and at the comparatively shallow depth in the crust which modern views seem now to imply for the birth of the oil globule?

In 1929, a laboratory for the study of the cold working of iron and steel was established in the University of Sheffield and equipped by firms engaged in the steel wire and strip industries with a rolling mill and draw-bench for experimental work, a fellowship and two research scholarships were provided by the Ironmongers' Company This laboratory has now been at work for a session, and has in progress a programme of research on the influence of the conditions of drawing on the properties of steel wire, especially with regard to its resistance to fatigue, and special instruments have been constructed for the purpose of the measurements. The behaviour of the cold-drawn wire in torsion, both continuous and alternating, is found to give a convenient means of following the changes in the progressive stages of drawing The influence of the form of the die and of other factors on the properties of cold-drawn mild steel bars is also under examination The rolling programme consists in a study of mild steel strip of the deep-drawing variety, and instruments have been constructed for the measurement of the pressures during rolling, and of the energy stored in the cold-worked metal

At the Fourth International Congress for Psychical Research, which was held this year at Athens and of which the *Transactions* have recently been published (London Society for Psychical Research, 1930), Sir Oliver Lodge discussed the reasons for the non-recognition of psychical research by the majority of the scientific world It would appear that he is of the opinion that eventually the sheer weight of evidence will overpower this hostility, which he thinks arises partly from a pardonable scepticism and partly from a vague recognition of the significance of psychical phenomena and consequent upheaval of ideas which must follow the acceptance of their reality It may well be, however, that the chief reason that scientific men are chary of recognising psychical research is that they are unable to perceive the weighty mass of evidence of which Sir Oliver speaks These, *Transactions* indicate the kind of things which engage the attention of psychical researchers Here are tales of raps and lights, of falling mortar and broken crockery, and even of showers of pebbles—of which some, strange to say, seemed to come out of the medium's hair! We read of sacred oleographs oozing human blood one day and on another exuding an organism usually found in very foul water we are told of an incident where a ghost had to come back to earth to persuade a medium to burn some letters which suddenly appeared in her hands Even Sir Oliver Lodge tells us a story of an occurrence in the presence of Sir William Crookes "on a well-lighted" dining table and in "full light", whereas in what appears to be the actual record of the case, it states that the phenomena took place at night in a room lighted only by three spirit lamps From the official proceedings at the Congress it appears that the next meeting will be held in London in the autumn of 1932, on the occasion of the jubilee of the Society for Psychical Research Although the French, Italian, and American representatives seem no longer to be associated with the organisation controlling the International Congress, its continuance is assured so long as it is supported by the British and German national committees

The projected opening of the Cape Cairo flying route on Mar 5 gives interest to a paper on air communication in Africa recently read to the Royal Society of Arts by Mr G E W Humphery, and published in its *Journal* on Feb 6 The route will follow British territory in the main, although it starts at Cairo As far as Khartoum the direction is straight and there is little difficulty about landing grounds Then a difficult bit of country begins and continues almost as far as Lake Victoria. For some months in the

year much of that country is under water, and on this part of the route it will be necessary, for the present at least, to use flying boats that can alight on the Nile and the lakes It is hoped, however, that before long aerodromes will be available, making an aeroplane service possible From Kisumu on Lake Victoria to Cape Town the surface conditions of the country offer no difficulties in the provision of landing places, but the aeroplanes must fly at a considerable elevation The proposed route is via Nairobi, Broken Hill, Salisbury, Bulawayo, Johannesburg, and Kimberley Three types of air craft will be employed, changes being made at Khartoum and Kisumu Speed will be about 100 miles per hour throughout, and a weekly service for passengers and mails is proposed There will be no night flying, and the through journey will take eleven days The opening flight on Mar 5 will provide connexion with Kenya and Tanganyika, but the first through flight to the Cape will be deferred about three months

The aims and methods of the land utilisation of Britain were explained by Dr L Dudley Stamp in a paper entitled "Land Utilisation Survey" read before the Royal Geographical Society on Feb 16 The primary object is to make a complete record of the uses to which the land of Britain is put at the present time Six different categories are recognised meadow and permanent grass, arable land, including rotation grass, heathland and moorland, forests and woodlands, gardens, and land agriculturally un productive The survey is to be recorded on the 'six-inch' Ordnance maps This entails roughly 22,000 quarter sheets, each showing six square miles The work is being done by volunteer surveyors in various parts of the country and is of such a nature that schools can give valuable help The Board of Education has re commended it to the notice of schools and emphasised its educative value The sheets when marked are to be sent to the central office at the London School of Economics There they will be reduced to a one inch scale It is then planned to publish, through the Ordnance Survey, a series of sheets corresponding to the 'one inch' popular series Many areas of the country are already arranged for, and several hundred volunteers are at work It is obviously desirable that the whole country should be surveyed simultaneously, so that useful comparisons can be made and con clusions drawn on the existing state of agriculture The completed survey will give precise information where statistics can give only average information

At the meeting of the Royal Microscopical Society on Feb 18, Dr Robert Chambers, professor of biology in the University of New York, gave a remarkable demonstration of his method of micro-dissection and micro-injection in an address on "The Nature of the Living Cell" Probably the most striking peculiarity of living matter, or protoplasm, is the fact that it exists only within the confines of microscopic dimensions Protoplasm is protoplasm only in the form of living cells, plant or animal, therefore the only direct method of studying its properties is through the compound microscope under magnifications varying from 150 to more than 1000 diameters. The micro-dissection and micro injection technique of Prof Chambers was evolved in order to make it possible to manipulate the protoplasm within the living cell The apparatus is a mechanical device for controlling the movements of spun glass micro-needles and pipettes within the field of the microscope An apparatus of this kind, built in 1920, was first demonstrated before the Royal Microscopical Society about six years ago Since then several different types of instrument have been developed by various workers The present apparatus is a model based upon the original one of 1920, but has been modified from year to year by the addition of various improvements, and is so constructed as to permit operations upon the living cell under the highest magnifications By means of this instrument many new facts have been discovered regarding the physical and chemical properties of protoplasm We now know, for example, that the nucleus in many cells is a fluid body and is more alkaline in reaction than the cytoplasm in which it is immersed The oxidation intensity of living protoplasm has also been determined by the injection into the living cell of dyes which are reducible, thus, when the colour disappears upon injection and can be made to reappear by the injection of an oxidising agent, we can be fairly certain that the protoplasm had reduced it in the first instance Similarly, by this method, the physical properties of the hitherto hypothetically regarded cell membrane have been made the object of intensive study

The new series of *Bulletins* which are being issued by the Ministry of Agriculture and Fisheries are attractively produced on antique paper and bound in stiff cut covers *Bulletin* No 20 (1930), entitled "Some Beneficial Insects", was formerly *Miscellaneous Publication* No 37, but has been rewritten and, in its new form, is now in its third edition There seems to be no doubt that an increasing number of practical growers and others are interested in knowing something about those insects that confer benefit upon man and which, for this reason, should not be destroyed This bulletin provides the general inquirer with the elementary facts concerning the life and behaviour of insect parasites and predators It also gives some idea as to how, in some cases, it is possible to take advantage of their propensities and utilise them on a large scale for controlling noxious forms of insect life We can commend the bulletin as being one of considerable educational value for rural and other schools It explains and directs attention to an aspect of Nature too often overlooked The two coloured plates add to its utility, since they represent accurately some of the chief kinds of beneficial insects prevalent in Great Britain The bulletin may be obtained from the Ministry of Agriculture and Fisheries, price 4*d*, post free

In the Ministry of Agriculture's new *Bulletin* No. 9 (1930), entitled "Bee Keeping", what was originally a sectional volume of collected leaflets has been revised and largely rewritten It has been prepared for the information and guidance of those who wish to keep bees, and to assist those who have already

gained some experience of the craft It is written in a plain, non-technical style, and controversial matters, such as those concerning the causative agents of foul brood, for example, are obviously outside the scope of an elementary publication of this kind The bulletin contains 55 pages of text and 26 illustrations, and may be purchased direct from the Ministry of Agriculture and Fisheries, price 9*d*, post free We welcome the new series of bulletins thus inaugurated, for there are many subjects that lend themselves to this method of treatment Accurate up-to-date information and reliable illustrations are a *sine qua non* in such publications The two bulletins briefly referred to are essentially popular in character, and the question may be raised as to whether there is also an opening for a second series of a more technical description

In his presidential address to the American Society of Parasitologists (published in *Science* of Jan 9), Dr N A Cobb pleads for more adequate and more accurate treatment of the Nematoda in text books and in courses of zoology He attributes the present unsatisfactory teaching on this subject to the fact that *Ascaris* is so commonly regarded as typical of the Nematodes, and this is responsible for such statements as that the only sense organs are papillæ on the lips, whereas "there is no lack of sense organs" in Nematodes He admits the difficulties of classification and of laboratory studies on the free living forms, which outnumber the parasitic forms, but would, nevertheless, so far as morphology is concerned, relegate *Ascaris* to the background, as it is "devoid of a single curious or interesting external feature to attract attention" There is much to be said for his plea that the study of the group would be more satisfactorily approached by the microscopic examination of small, living, transparent forms These could be supplemented by the study of a transverse section, and for this purpose it would be difficult to find a better example than *Ascaris*, in which the histology, especially of the gut, muscles, and reproductive organs, is so diagrammatically clear The retention of *Ascaris* in this way in the practical course would afford the opportunity of directing the student's attention to the great historical importance of *Ascaris* in the development of our knowledge of germ cells and of the nature and behaviour of chromosomes and other cell elements

An interesting and suggestive subject is discussed by A S le Souef in the *Medical Journal of Australia* for November—"Actions, Reactions, and Traits common to Men and Animals" From his own observations in the Zoological Garden at Sydney and from the writings of other naturalists, the author has collected examples of activities in birds and beasts which recall human actions Some of these are the play of elephants, seals, and emus, the collecting instinct of many rodents and of bower-birds, which he suggests may be a forecast of the human collecting of birds' eggs and 'hard cash'; the song of birds and the dances of birds and monkeys, the thieving and the teasing tendencies of certain birds, instinctive fears, and so on It is possible that there may be a direct ancestral connexion between these animal actions and human actions, but it is unlikely, and Mr le Souef pushes his conclusion beyond the evidence when he states that "man in his body and mind and the resultant actions therefrom is an almost complete embodiment of the lower animals, combining in some degree the attributes of all species" Man, as a living being, possesses the functions common to all living organisms, and that these should sometimes find similar modes of expression, even in creatures which have no direct ancestral relation, like man and birds, is scarcely to be wondered at In these actions and reactions we are looking upon common expressions of the essential life activities, but perhaps this is all that Mr le Souef means

Volume 22 of the *Collected Researches* of the National Physical Laboratory is a quarto volume of more than 400 pages devoted entirely to electrical matters The 21 memoirs which are included have appeared in the *Proceedings* of scientific or technical societies or in other scientific publications during the past six years, and more than half of them during the last two years Five of the memoirs relate to the carrying capacity and other properties of cables used in power transmission and come within the purview of the Electrical Industries Research Association or the Engineering Standards Association One is devoted to the design of an air condenser which is a pure capacitance, and another to an accurate method of measuring dielectric constants of liquids The remaining memoirs deal with problems which have arisen in wireless telegraphy—the properties of the antennæ and of the beam propagated, the construction and performance of instruments or apparatus used in wireless measurements, including quartz oscillators, nine of these memoirs relate to researches which were undertaken for the Radio Research Board No one can look through the volume without being struck by the importance of the part the Laboratory is playing in the solution of the problems which arise in the work of the research associations which the industries have formed under the auspices of the Department of Scientific and Industrial Research

The 'Text' volume, the final one of the three annual volumes constituting the Registrar General's Statistical Review for 1929, has recently been published (H M Stationery Office 2*s* 6*d* net) It contains the official analysis of the vital statistics contained in Parts 1 (Medical) and 2 (Civil), issued recently The population (England and Wales) at the middle of the year is estimated at 39,607,000 persons—18,969,000 males and 20,638,000 females The figures indicate a higher growth among males, and the sex inequality, expressed as 1096 females in 1921, is thereby assumed to have been reduced to 1088 females, at the mid year, per 1000 males The deaths ascribed to cancer numbered 56,896, the highest number yet recorded for any one year There is a marked decrease of mortality from conditions associated with alcoholism Tables have been introduced

showing the mortality of the first 30 minutes of life, the reduction in the mortality from diabetes since the introduction of insulin (mortality from this disease at ages above fifty-five years, however, continues to increase), and reduction in the mortality from pernicious anæmia as a result of the new treatment with liver

The honour of knighthood has been conferred by the King upon Capt Malcolm Campbell for his achievement of the world's land speed record on Feb 5

An earthquake was recorded at Kew Observatory at 5 h 44 m 42 s G.M T on Feb 20 The epicentre is estimated to have been in Korea, near lat 39° N, long 126° E The initial impulse was very sharp, but the amplitudes of the main phase were small The shock is believed to have originated at a greater depth than usual, probably about 250 miles

Sir James Jeans has been awarded the Franklin Medal for 1931 by the Franklin Institute, Philadelphia, "in recognition of his many fruitful contributions to mathematical physics, especially in the realms of the dynamical theory of gases and the theories of radiation, and of his challenging explanations of astronomical problems and his illuminating expositions of modern scientific ideas"

It is announced in the *Times* that Capt W P B Beal, formerly principal veterinary officer of the Gold Coast, has been appointed superintendent of the new zoological park of the Zoological Society of London at Whipsnade Capt Beal has had considerable experience in supervising the health of animals, planning experimental stations, and road making, and will be largely engaged in the development of the Whipsnade estate It is expected that the new park will be open at Whitsuntide

Influenza has been prevalent all over Great Britain during the last few weeks, and for the week ended Feb 14 the deaths from this disease numbered 458 in England and Wales and 116 in London The disease is also widespread in the United States of America, and we learn from a *Daily Science News Bulletin* (Science Service, Washington, D C) that for the week ended Jan 31 a total of 8362 cases was reported to the U S Public Health Service

The Ministry of Health has issued a circular respecting the outbreak of paratyphoid fever in Essex Between Feb 1 and 14, 172 known cases have occurred in the Epping Urban, Epping Rural, and Loughton districts, and the Borough of Walthamstow The infection in all cases has been caused by the paratyphoid B type of bacillus, the illness has been severe in many cases, and up to Feb 21 seven deaths occurred The epidemic has been traced to infection of a particular milk supply at a dairy farm in the Epping Rural District. The infection appears to have been introduced by one of the employees on the farm, who, unknown to himself, was suffering from a mild attack of paratyphoid fever while at work and handling the milk before distribution

The third annual exhibition of apparatus relating to television, picture telegraphy, and talking films is to be held by the Television Society at University College, London, on April 15, from 2.30 P.M to 9 P M The Exhibition Committee invites offers from research laboratories and institutions and from individual research workers and those engaged in experiments in any of these subjects, such offers to be sent as soon as possible to the Hon Secretary, Mr W G W Mitchell, Television Society, 4 Duke Street, Adelphi, London, W C 2, and giving particulars of space and any other facilities required. As on previous occasions, members of the Society exhibiting apparatus have the right of entering their exhibit in the annual competition for the Tuke Cup, which is awarded by an independent committee of judges for the most meritorious exhibit, in relation to television or cognate subjects

A catalogue of second-hand books, some 500 in number, on botany, ecology, entomology, forestry, natural history, ornithology, zoology (invertebrate and vertebrate), has just been issued by Messrs W and G Foyle, Ltd, 119 Charing Cross Road, W C 2 Copies are to be had free upon application

The Prague Summer School was inaugurated last year to afford English speaking visitors, especially those interested in educational matters, an opportunity of attending a series of lectures on various aspects of Czechoslovak and central European civilisation and cultural life The Summer School will again be held this year during the long vacation, on July 20–Aug 8 The scope of the syllabus has been extended to include, in addition to other new subjects, an account of Czechoslovak contributions to the natural sciences. In connexion with the lectures a number of interesting excursions have been arranged so that members may see places of historical interest, the Karlsbad and Marienbad spas and springs, the radium mines at Jáchymov, etc The director of the Summer School is Dr B Trnka, 55 Smetana Square, Prague, Czechoslovakia

An advanced course in oriental studies will be held at the School of Oriental Studies, Finsbury Circus, London, on Mar 2, 3, and 4 The lectures will be given by Prof B Hrozny, professor of ancient eastern history in the Charles University of Prague, the subject being the "Excavations of Kultepe" and "The Hittites" The first lecture will deal with Prof Hrozny's travels in Asia Minor and the excavations at Kultepe which led to the discovery of the now famous Assyrian merchants' archives of 2000 B C This lecture will be illustrated by some hundred coloured lantern slides The second and third lectures, on the Hittites, will deal with the decipherment of the Hittite language and its recognition as Indo-European, the non-Indo-European Khattish and other newly discovered peoples of Asia Minor and North Mesopotamia, the Luish, in essence non-Indo-European, the Khurrish, who spoke a non-Indo-European language and are identified with the Horites of the Old Testament, and the Mitanni, who are of Aryan, or rather Indian, origin. Finally, Prof Hrozny will discuss the relations of

the Hittites and the Greeks At the first lecture the chair will be taken by Dr A E Cowley, Bodley's Librarian in the University of Oxford The lectures, which will be delivered in English, will begin on each day at 5 15 P.M, and admission will be free and without ticket

APPLICATIONS are invited for the following appointments, on or before the dates mentioned — A reader in statistics in the University of Cambridge —The Registrary, The Registry, Cambridge (Mar 4) A scientific instrument maker at the University College of South Wales and Monmouthshire—The Registrar, University College, Cathays Park, Cardiff (Mar 7) An assistant lecturer in science at the National Society's Training College for Teachers—The Principal, Training College, Berridge House, Fortune Green Road, W Hampstead, N W 6 (Mar 9) Senior technical assistants and technical assistants at Admiralty establishments near London and in Portsmouth—The Secretary of the Admiralty, C E Branch, Whitehall, S W 1 (Mar 10) A director of the Manchester and District Radium Institute—The Hon Secretary, Radium Institute, Nelson Street, Manchester (Mar 14) A lecturer in economic history in the University of Liverpool—The Registrar, The University, Liverpool (Mar 16) A principal and professor of organic chemistry at the Royal Institute of Science, Bombay—The High Commissioner for India, General Department, India House, Aldwych, W C 2 (Mar 21) A biochemist, a technician in the research laboratory, and a junior biologist, each under the Newfoundland Fisheries Research Commission—The Newfoundland Government Office, 58 Victoria Street, S W 1 (Mar 22) A professor of chemistry at the Heriot Watt College, Edinburgh—The Principal, Heriot Watt College, Edinburgh (Mar 26) A professor of mechanical engineering in the Engineering College of the Benares Hindu University—The Principal, Engineering College, Benares Hindu University, Benares, India (April 5) A principal of the Northern Polytechnic—The Clerk, Northern Polytechnic, Holloway, N 7 (April 17) Lecturers in, respectively, pure mathematics, civil engineering, and botany in the Queen's University of Belfast—The Secretary, Queen's University, Belfast (April 19) A lecturer in geography and elementary science at the Truro Training College—The Principal, Training College, Truro A lecturer in physical training and hygiene at Southlands Training College—The Principal, Southlands Training College, Wimbledon Park Side, S W 19

Our Astronomical Column

A Large Sunspot —A large group of sunspots recently visible is the largest that has appeared for over a year The group when near the sun's east limb on Feb 14 was quite small, but between Feb 17 and 19 it developed rapidly, and by Feb 21 had become a conspicuous stream of spots easily visible to the naked eye The central meridian passage of the group occurred on Feb 20 8, its latitude was 6°, and its area on Feb 17, 19, and 21 was respectively 150, 900, and 1700 millionths of the sun's hemisphere On Feb 19, spectroscopic observations made at 15^h showed a mass of hydrogen to be descending into the following member of the group with the velocity of about 30 km /sec On succeeding days the group was not unusually active, so far as rather limited observations showed It may be remarked that sunspots during 1930 were both appreciably less in number and smaller than in 1929 The sunspot minimum may be expected in two or three years' time

A Faint Cluster near Betelgeux —*Circular* No 309 of the U A I Bureau contains a report from Dr Schuller, of the National Observatory, Prague, on a hitherto unknown cluster of faint stars in the position R A 5^h $40 \cdot 7^m$, N Decl 7° 21′, equinox 1855 0 Exposure of $5\frac{1}{2}$ hours showed an open cluster of stars the magnitude of which is between 16 and 18, close to the edge of Barnard's dark channel No 36 The cluster is not shown on Barnard's photographs, the Franklin Adams plates, or on those in the Atlas of selected areas None of these extend to such faint magnitudes, their limit is about $15\frac{1}{2}$ mag The distance of the cluster is roughly estimated as 30,000 light years, assuming that its brightest stars are of type *A* Its proximity to the dark lane suggests, however, that there may be some absorption of light, which would make the distance less

Search for Possible Additional Satellites of Distant Planets.—It is well known that Sir W Herschel announced the existence of six satellites of Uranus, but only four are now recognised The possibility of the existence of additional satellites both of Uranus and Neptune, has been considered by many, we learn from a *Daily Science News Bulletin* issued by Science Service of Washington, D C, that a photographic search for possible new satellites has been made by Mr W H Christie, using the 60 inch reflector and giving exposures from one to three hours. The result however, was negative in each case Mr Christie concludes that if any bodies of the kind exist, they are not brighter than mag 19 in the case of Uranus, or mag 18 5 in that of Neptune Even this negative result is of interest, and may save time, as establishing the uselessness of searching for such bodies with any smaller instrument It would seem worth while to make an attempt in the case of Pluto, success is unlikely, but would be of value in giving Pluto's mass

New Star Catalogue from Yale University —Prof F Schlesinger inaugurated a new era in star catalogues when he published, four years ago, a catalogue of stars in the zone between 50° and 55° North Declination, the places being derived from photographs with a wide angle lens that included the whole width of the zone on each plate He has now produced a similar catalogue of 7727 stars in the zone 55° to 60° The zone was covered by 72 plates, the centres of which were 20^m of R A apart, so that nearly all the stars appear on two plates They were taken between 1915 and 1917, but not measured until 1926 and 1927, this being done by Miss Ida Barney Proper motions are deduced for almost all the stars in the catalogue These will enable improved places to be obtained for the stars used as reference stars in the astrographic zones They had previously been brought up from the Astr Gesell Catalogues without proper motion in the majority of cases The probable error of the star positions in the new catalogue is given as $\pm 0 \cdot 15''$ in each co-ordinate

Research Items

Finger-prints of Twins.—A study of the finger-prints of twins has been made by Prof. H. H. Newman (*Jour. Genet.*, vol. 23, No. 3). The material consisted of the prints of 100 pairs of same sexed twins, 50 of whom were classed as identical and 50 as dizygotic or fraternal. He regards the whorl as the most primitive pattern, while some have given this place to the loop, which occurs in primitive form in anthropoids. He finds that the finger-prints of identical twins may be extraordinarily alike in pattern, although they always differ in minutiæ. The distribution of whorls, loops, and arches is the same in both types of twins and agrees with that of the general population. Radial loops and radial whorls are largely confined to the index finger. This is interpreted as a result of the early dichotomy of the limb bud, separating the thumb primordium from the rest of the fingers and tending to produce in the index finger a pattern the reverse of that in the thumb. Tented arches, which are common on forefingers, are interpreted as cases of partial asymmetry reversal. In identical twins the patterns on one or both hands resemble the hands of the other twin more strongly than do opposite hands of the same individual. The reverse is true of fraternal twins, and this difference can be used as a criterion for classifying doubtful twin pairs. If the finger patterns in human twins are compared with the scale patterns in armadillos, it is found that in both man and the armadillo parallel imaging is about twice as frequent as mirror-imaging of asymmetrical peculiarities. This leads to the conclusion that monozygotic twins in man arise in the same general way as the quadruplets which normally occur in the armadillo, that is, by a process of budding in the early embryo.

Botulism in Wild Ducks.—For several years the death of millions of wild ducks in the western States of America has been attributed to poisoning due to the alkalinity of inland waters after a spell of drought. Further investigation, according to Science Service of Washington, D.C., has shown that there are difficulties in accepting the idea of alkalinity poisoning, one reason being that in some areas where the water was highly alkaline the disease was very much less prevalent than in others where the alkalinity was small, although in general the distribution of the disease agreed with the regions of alkaline waters in the United States. Dr. E. R. Kalmbach, of the U.S. Biological Survey, has now shown that the disease is a form of botulism poisoning, and that the causative organism is different from that which affects human beings. How the organism gets into the duck's body in the first place is not known; but diseased tissues of one bird fed to another produced symptoms of the disease. One attack gives no immunity from another.

Chinese Fishes.—Papers on the fishes of China have appeared in recent numbers of two scientific magazines published in that country; one concludes Henry W. Fowler's account of "The Sharks, Rays, and related Fishes of China" (*Hong Kong Naturalist*, Nov. 1930, p. 177), and has, in addition to short diagnostic accounts of species and clear outline drawings, a list of English, Latin, and Chinese names of all the forms. The second paper, by the same author, describes a collection mainly of fresh-water fishes, obtained at Tsinan, China (*Peking Nat. Hist. Bull.*, vol. 5, Dec. 1930, p. 27). The collection contained twenty-two species, of which two gobies, belonging to the genera *Acanthogobius* and *Aboma*, are described as new. In the same magazine (p. 15) J. T. Nichols gives the synonymy of some Chinese fresh-water fishes in a paper which may be regarded as supplementary to the "provisional check-list" of the fresh-water fishes of China published as a *Bulletin* of the American Museum of Natural History in 1928.

Crustacea of the Vanderbilt Museum.—The *Bulletin of the Vanderbilt Marine Museum*, vol. 2 (Scientific Results of the Cruises of the Yachts *Eagle* and *Ara*, 1921–1928, William K. Vanderbilt commanding. Crustacea: Stomatopoda and Brachyura, by Lee Boone. Huntingdon: privately printed, 1930), is one of the scientific publications of the Vanderbilt Museum owned by Mr. William K. Vanderbilt, who made extensive collections in various parts of the world, and these collections housed in his own museum, Huntingdon, Long Island, are being described in a series of bulletins, of which the present volume is the second, the first dealing with fishes. There are several more volumes to come, which will be a great help to all zoologists. Miss Lee Boone is well known for her studies on crabs, and has dealt here with the Stomatopoda and the Brachyura in great detail. Most of the material was obtained in the West Indian region, five separate cruises in five consecutive years having been conducted by Mr. Vanderbilt, besides later work in the West Indies, supplementing the Galapagan Expedition. There are also collections from the Labrador New England region, the tropical American Pacific region, and the Mediterranean, representing terrestrial and littoral, besides deep water species. A large number of little-known forms are present, and much that is new is included with regard to their distribution, besides colour and notes on habits made on the spot by Mr. Vanderbilt. Some of the crabs are well-known northern species, such as *Portunus holsatus* and *Stenorhynchus longirostris*, but others are extremely rare. All are carefully described and well figured either by excellent photographs or by good line drawings, and the whereabouts of the type specimen (if possible) is given, with notes on general distribution and synonymy.

Culture of Entamœba.—L. R. Cleveland and E. P. Sanders (*Arch. f. Protistenk.*, 70, 1930) state that when *Entamœba histolytica* is cultivated on slants of liver infusion agar, covered with horse serum in saline (1 : 6) and a small amount of sterile rice-flour added to each tube, "the amœbæ become as numerous as blood cells are in the blood stream." A photomicrograph of a culture illustrates the abundance of the entamœbæ in such a culture. A pure line was established from a single cyst and the authors have made many studies on this pure line, for example, variation in size. They state that the size of the cysts when plotted produces a clear-cut unimodal size distribution curve, as would be expected in a pure line. The authors express the view that *Councilmania dissimilis* is an atypical *E. histolytica* "produced, for the most part, by fixation in Schaudinn's fluid heated to 60° C.", that *C. lafleuri* may very well be atypical *E. coli*, and that the genus *Councilmania* is invalid. The authors have been able to produce countless millions of cysts of *E. histolytica*, and they discuss the conditions of encystation. They have also studied the excystation and the production of the quadrinucleate amœba and the eight trophic amœbæ which result therefrom. Their work confirms that of Dobell on these stages. They report that the octonucleate cysts occasionally seen in *E. histolytica* result from the encystation of binucleate trophic amœbæ, and

they describe a process of multiple fission in which "everything occurs that occurs during encystation except that no cyst-wall is formed and motility is not lost" In a further paper Cleveland and Collier (*Amer Jour Hygiene*, **12**, 1930) give details of the improved methods of cultivation of *E histolytica*

A New Endoskeletal Organ in the Hind Leg of the Halticinæ.—In a recent note (*Zool Anzeiger*, **92**, 9/10, 1930) R J W Lever has announced that while he was examining a Halticine beetle (*Oxygona acutangula* Chevr) in Trinidad to confirm the presence of Maulik's organ in the hind femur (see NATURE, Oct 26, 1929, 668), he noticed another structure He gives a short description and six illustrations to show the form and its situation relative to other structures in the femur It seems that the importance of Mr Lever's note lies in the fact that a more comprehensive study of the structure of the femora of these extremely mobile insects is indicated It is suggested that this study may be suitably taken up by those who have the opportunity of getting a variety of fresh material Not only will such study throw light on the general question of jumping locomotion of insects, but it will in a great measure enlarge our views on relationships within the group

Banana Transport—As *Report* No 36 of the Empire Marketing Board, Claude C Wardlaw and Lawrence P M'Guire, of the Low Temperature Station, Imperial College of Tropical Agriculture, give an account of "The Behaviour and Diseases of the Banana in Storage and Transport" In view of the fact that the so called 'Panama disease' has spread to the West Indies from South America, where it has forced the abandonment of thousands of acres cultivated with the 'Gros Michel' strain of banana, it seems imperative to see whether other varieties, apparently not so susceptible to the disease, can be grown for export Many varieties are available but are not such hardy travellers or have other undesirable qualities The authors, as a result of preliminary trials on bulk storage under conditions equivalent to a ship's hold, report favourably on the 'Cavendish' variety They discuss measures for shipping bananas with a minimum of trouble from disease, and examine, from this point of view, the new practice of cutting the stalks with a sterile knife and vaselining the cut surfaces With careful handling of the fruit, this method may give still better results Packing in paper bags may lead to complications because of the difficulty in ventilation and in rapid cooling, perforated paper bags may prove useful, but the practice which is most strongly recommended to the exporter is that, when he packs in crates, the whole bunch should be pre cooled before cutting up for packing

The Outer Layers of the Earth—In the *Bull Seismolog Soc Am*, pp 41 52, 1930, Daly discusses the discontinuities revealed by seismological research on the shell structure of the earth From four different kinds of experimental evidence he deduces that the 'seismically effective' compressibility of a rock is about 20 per cent less than its compressibility as determined by the high-pressure method He notes, however, that specially designed experiments to test this idea are urgently needed The tentative conclusion, combined with seismic data, suggests that the uppermost layer of a continental block is essentially granitic down to about 30 km A shell of granodiorite or quartz-diorite is indicated below this to a depth of some 45 km The next shell is interpreted as gabbro down to 60 or 70 km Below this there is, according to Gutenberg, a drop in the velocities of the longitudinal and transverse waves which is thought to represent the change from crystalline to vitreous conditions Daly considers that vitreous basalt may extend down to 1200 km, and that there is no suggestion in the wave velocities of a shell of peridotite near the earth's surface This interpretation implies that all the exposed peridotite of the earth is a derivative from basaltic magma, a thesis difficult to support It also implies that the basaltic layer has practically no heat of radioactive origin generated within it Moreover, it should not be overlooked that the outer 30 km layer visibly contains large masses of granodiorite and more basic rocks, represented in depth by gneisses and amphibolites, the suggestion of 30 km of granite, therefore, can scarcely be readily accepted

Length of Glaciers—The work of the International Glacier Commission, which from 1894 until 1913 published an annual report on the variations in lengths of certain glaciers, was interrupted by the European War Its work has now been handed over to the Hydrological Section of the International Research Council In order to make up with arrears before the resumption of the annual report, a statistical account has now been published of the observations from 1913 to 1928 (*Rapport de la commission des glaciers, Bulletin* 14, Section d'Hydrologie Union Géodésique et Géophysique Internationale, Venice, 1930) Glaciers are grouped geographically and variations in length, where they have occurred, are given to the nearest half metre In some areas only one figure can be given for the whole period of the War The observations come from various sources, and include the French, Swiss, and Italian Alps, Sweden, and Norway A supplementary report on more scattered and less complete data is promised The general impression given by the figures is one of retreat, but there are notable exceptions The most striking is perhaps the frequent record of the advance of Norwegian glaciers since about the years 1921 and 1922 In the scanty Swedish records there is nothing comparable Alpine records show very variable conditions, but the increase of the Mont Blanc glaciers was most marked about the years 1914–20 Several of the glaciers of the Rhone basin showed an increase towards the end of this period

The Measurement of Spark-over Voltages by a Sphere-gap—In the *Scientific Papers* of the Institute of Physical and Chemical Research, Tokyo, vol 14, p 278, Nov 1930, T Nishi and Y Ishiguro give a helpful account of the anomalous phenomena when spark over voltages are employed for measuring the electrical pressure In high pressure engineering it is common practice to measure the crest value of alternating pressures by means of a spark gap with spherical electrodes It generally happens, however, that a few stray and erratic sparks occur at low voltages before the gap gets into the condition where a definite steady voltage always produces a spark. When the electrodes are small the preliminary sparks at low voltages do not often occur, and rarely affect ordinary testing Neither do they occur when the spark gap is very small compared with the radius of either electrode With spheres a metre in diameter, placed a metre apart, the first flash-over occurred at a voltage which was 6 per cent less than that obtained in the subsequent tests, all of which gave practically the same result When the surfaces of the electrodes were carefully cleaned by a cloth soaked in alcohol and the test repeated, the first flash occurred when the pressure was 30 per cent less than its normal value, the next occurred when the pressure

was 12 per cent under the normal, the subsequent flashes occurring at practically the same voltage Washing the surface with alcohol was very effective in lowering the pressure at which the preliminary sparks took place The curious behaviour of the sparks is attributed to the surface conditions, but the exact cause the authors were unable to determine They advise that the first few readings for a fixed spark setting should be rejected and only the steady value given

An Electrical Pendulum — A novel electrically maintained pendulum which was exhibited by the British Thomson Houston Company at the recent Exhibition of the Physical and Optical Societies is illustrated in Fig 1 A primary coil *A* carries a high frequency current generated by a valve in the box, a secondary coil *B*, forming with its condenser *C* a separately tuned circuit, is suspended from knife

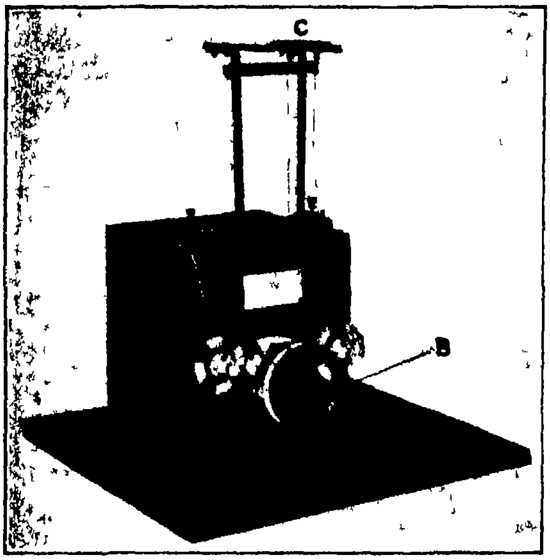

FIG 1

edges, so that when swinging to and from *A* the coupling between the two is varied periodically The electrical constants of the circuits are so chosen that the natural frequency of the secondary is higher than that of the primary when *B* is at the outward point of its swing At this position the two currents are in phase, and *B* is attracted, but as it approaches *A* an abrupt change of phase of almost 180° takes place when the coupling has increased to a certain critical amount, so that the force between the two becomes repulsive Simultaneously the frequency assumes a higher value On the outward path of *B* the converse changes occur, and so the swinging is maintained The two values of frequency are shown by the alternate lighting of two lamps connected to separate coils F_1 and F_2, which are tuned by small condensers The abrupt phase-changes are those which give rise to the well known 'double click' effect obtained with resonant circuits

Trajectories of Electrons in Valves —It is of some importance in connexion with thermionic devices to be able to find the paths of electrons within the apparatus When small quantities of gas are of no consequence, the orbits may readily be demonstrated by their optical effects in the inter electrode spaces —as, for example, has been done by E Brüche in a recent test of Størmer's theory of the aurora (*Die Naturwissenschaften*, Dec 12)—but for various reasons this method is not always permissible, and possibly not always accurate An arrangement due to Mr A J Maddock, of the British Thomson Houston Company, which was shown at the recent Exhibition of the Physical and Optical Societies, still enables the points of impact of electrons on an anode to be found in a high vacuum The anode is coated with carbon, which becomes strongly incandescent at any place where there is a concentration of the electron beams, rendering it very easy to show, for example, the effect of the grid potential in concentrating the beams to a greater or less degree The actual valve exhibited had an *M* shaped oxide coated filament, and was operated with an alternating anode potential of 700 volts peak value
